A complex interaction between the retroviral envelope glycoproteins and a specific cell surface protein initiates viral entry into cells. The avian leukosis-sarcoma virus (ALV) group of retroviruses provides a useful experimental system for studying the retroviral entry process and the evolution of receptor usage. In this study, we demonstrate that evolutionary pressure on subgroup A ALV [ALV(A)] entry exerted by the presence of a competitive inhibitor, a soluble form of the ALV(A) Tva receptor linked to a mouse immunoglobulin G tag (quail sTva-mIgG), can select different populations of escape variants. This escape population contained three abundant ALV(A) variant viruses, all with mutations in the surface glycoprotein hypervariable regions: a previously identified variant containing the Y142N mutation in the hr1 region; a new variant with two mutations, W141G in hr1 and K261E in vr3; and another new variant with two mutations, W145R in hr1 and K261E. The W141G K261E and W145R K261E viruses escape primarily by lowering their binding affinities for the quail Tva receptor competitive inhibitor while retaining wild-type levels of binding affinity for the chicken Tva receptor. A secondary phenotype of the new variants was an alteration in receptor interference patterns from that of wild-type ALV(A), indicating that the mutant glycoproteins are possibly interacting with other cellular proteins. One result of these

altered interactions was that the variants caused a transient period of cytotoxicity. We could also directly demonstrate that the W141G K261E variant glycoproteins bound significant levels of a soluble form of the TvbS3 ALV receptor in a binding assay. Alterations in the normally extreme specificity of the ALV(A) glycoproteins for Tva may represent an evolutionary first step toward expanding viral receptor usage in response to inefficient viral entry.

Men, R., T. Yamashiro, et al. (2004). "Identification of Chimpanzee Fab Fragments by Repertoire Cloning and Production of a Full-Length Humanized Immunoglobulin G1 Antibody That Is Highly Efficient for Neutralization of Dengue Type 4 Virus." *J. Virol.* **78**(9): 4665-4674.

<http://jvi.asm.org/cgi/content/abstract/78/9/4665>

A safe and effective dengue vaccine is still not available. Passive immunization with monoclonal antibodies from humans or nonhuman primates represents an attractive alternative for the prevention of dengue virus infection. Fab monoclonal antibodies to dengue type 4 virus (DENV-4) were recovered by repertoire cloning of bone marrow mRNAs from an immune chimpanzee and analyzed for antigen binding specificity, VH and VL sequences, and neutralizing activity against DENV-4 in vitro. Fabs 5A7, 3C1, 3E4, and 7G4 were isolated from a library constructed from a chimpanzee following intrahepatic transfection with infectious DENV-4 RNA. Fabs 5H2 and 5D9, which had nearly identical VH sequences but varied in their VL sequences, were recovered from a library constructed from the same chimpanzee after superinfection with a mixture of DENV-1, DENV-2, and DENV-3. In radioimmunoprecipitation, Fab 5A7 precipitated only DENV-4 prM, and Fabs 3E4, 7G4, 5D9, and 5H2 precipitated DENV-4 E but little or no prM. Fab 3E4 and Fab 7G4 competed with each other for binding to DENV-4 in an enzyme-linked immunosorbent assay, as did Fab 3C1 and Fab 5A7. Fab 5H2 recognized an epitope on DENV-4 that was separate from the epitope(s) recognized by other Fabs. Both Fab 5H2 and Fab 5D9 neutralized DENV-4 efficiently with a titer of 0.24 to 0.58 {micro}g/ml by plaque reduction neutralization test (PRNT), whereas DENV-4-neutralizing activity of other Fabs was low or not detected. Fab 5H2 was converted to full-length immunoglobulin G1 (IgG1) by combining it with human sequences. The humanized chimpanzee antibody IgG1 5H2 produced in CHO cells neutralized DENV-4 strains from different geographical origins at a similar 50% plaque reduction (PRNT50) titer of 0.03 to 0.05 {micro}g/ml. The DENV-4 binding affinities were 0.42 nM for Fab 5H2 and 0.24 nM for full-length IgG1 5H2. Monoclonal antibody IgG1 5H2 may prove valuable for passive immunoprophylaxis against dengue virus in humans.

Minisini, R., C. Tulone, et al. (2003). "Constitutive Inositol Phosphate Formation in Cytomegalovirus-Infected Human Fibroblasts Is due to Expression of the Chemokine Receptor Homologue pUS28." *J. Virol.* **77**(8): 4489-4501.

<http://jvi.asm.org/cgi/content/abstract/77/8/4489>

An open reading frame (ORF), US28, with homology to mammalian chemokine receptors has been identified in the genome of human cytomegalovirus (HCMV). Its protein product, pUS28, has been shown to bind several human CC chemokines, including RANTES, MCP-1, and MIP-1{alpha}, and the CX3C chemokine fractalkine with high affinity. Addition of CC chemokines to cells expressing pUS28 was reported to cause a pertussis toxin-sensitive increase in the concentration of cytosolic free Ca²⁺. Recently, pUS28 was shown to mediate constitutive, ligand-independent, and pertussis toxin-insensitive activation of phospholipase C via Gq/11-dependent signaling pathways in transiently transfected COS-7 cells. Since these findings are not easily reconciled with the former observations, we analyzed the role of pUS28 in mediating CC chemokine activation of pertussis toxin-sensitive G proteins in cell membranes and phospholipase C in intact cells. The transmembrane signaling functions of pUS28 were studied in

HCMV-infected cells rather than in cDNA-transfected cells. Since DNA sequence analysis of ORF US28 of different laboratory and clinical strains had revealed amino acid sequence differences in the amino-terminal portion of pUS28, we compared two laboratory HCMV strains, AD169 and Toledo, and one clinical strain, TB40/E. The results showed that infection of human fibroblasts with all three HCMV strains led to a vigorous, constitutively enhanced formation of inositol phosphates which was insensitive to pertussis toxin. This effect was critically dependent on the presence of the US28 ORF in the HCMV genome but was independent of the amino acid sequence divergence of the three HCMV strains investigated. The constitutive activity of pUS28 is not explained by expression of pUS28 at high density in HCMV-infected cells. The pUS28 ligands RANTES and MCP-1 failed to stimulate binding of guanosine 5'-O-(3-[³⁵S]thiotriphosphate to membranes of HCMV-infected cells and did not enhance constitutive activation of phospholipase C in intact HCMV-infected cells. These findings raise the possibility that the effects of CC chemokines and pertussis toxin on G protein-mediated transmembrane signaling previously observed in HCMV-infected cells are either independent of or not directly mediated by the protein product of ORF US28.

Moorman, N. J., D. O. Willer, et al. (2003). "The Gammaherpesvirus 68 Latency-Associated Nuclear Antigen Homolog Is Critical for the Establishment of Splenic Latency." *J. Virol.* **77**(19): 10295-10303.

<http://jvi.asm.org/cgi/content/abstract/77/19/10295>

Open reading frame 73 (ORF 73) is conserved among the gamma-2-herpesviruses (rhadinoviruses) and, in Kaposi's sarcoma-associated herpesvirus (KSHV) and herpesvirus saimiri (HVS), has been shown to encode a latency-associated nuclear antigen (LANA). The KSHV and HVS LANAs have also been shown to be required for maintenance of the viral genome as an episome during latency. LANA binds both the viral latency-associated origin of replication and the host cell chromosome, thereby ensuring efficient partitioning of viral genomes to daughter cells during mitosis of a latently infected cell. In gammaherpesvirus 68 ({gamma}HV68), the role of the LANA homolog in viral infection has not been analyzed. Here we report the construction of a {gamma}HV68 mutant containing a translation termination codon in the LANA ORF (73.STOP). The 73.STOP mutant virus replicated normally in vitro, in both proliferating and quiescent murine fibroblasts. In addition, there was no difference between wild-type (WT) and 73.STOP virus in the kinetics of induction of lethality in mice lacking B and T cells (Rag 1^{-/-}) infected with 1,000 PFU of virus. However, compared to WT virus, the 73.STOP mutant exhibited delayed kinetics of replication in the lungs of immunocompetent C57BL/6 mice. In addition, the 73.STOP mutant exhibited a severe defect in the establishment of latency in the spleen of C57BL/6 mice. Increasing the inoculum of 73.STOP virus partially overcame the acute replication defect observed in the lungs at day 4 postinfection but did not ameliorate the severe defect in the establishment of splenic latency. Thus, consistent with its proposed role in replication of the latent viral episome, LANA appears to be a critical determinant in the establishment of {gamma}HV68 latency in the spleen post-intranasal infection.

Muir, W. B., R. Nichols, et al. (2002). "Phylogenetic Analysis of Varicella-Zoster Virus: Evidence of Intercontinental Spread of Genotypes and Recombination." *J. Virol.* **76**(4): 1971-1979.

<http://jvi.asm.org/cgi/content/abstract/76/4/1971>

A heteroduplex mobility assay was used to identify variants of varicella-zoster virus circulating in the United Kingdom and elsewhere. Within the United Kingdom, 58 segregating sites were found out of the 23,266 examined (0.25%), and nucleotide diversity was estimated to be 0.00063. These are an order of magnitude smaller than comparable estimates from herpes simplex virus

type 1. Sixteen substitutions were nonsynonymous, the majority of which were clustered within surface-expressed proteins. Extensive genetic correlation between widely spaced sites indicated that recombination has been rare. Phylogenetic analysis of varicella-zoster viruses from four continents distinguished at least three major genetic clades. Most geographical regions contained only one of these three strains, apart from the United Kingdom and Brazil, where two or more strains were found. There was minimal genetic differentiation (one or fewer substitutions in 1,895 bases surveyed) between the samples collected from Africa (Guinea Bissau, Zambia) and the Indian subcontinent (Bangladesh, South India), suggesting recent rapid spread and/or low mutation rates. The geographic pattern of strain distribution would favor a major influence of the former. The genetic uniformity of most virus populations makes recombination difficult to detect. However, at least one probable recombinant between two of the major strains was found among the samples originating from Brazil, where mixtures of genotypes co-occur.

Narezkina, A., K. D. Taganov, et al. (2004). "Genome-Wide Analyses of Avian Sarcoma Virus Integration Sites." *J. Virol.* **78**(21): 11656-11663.

<http://jvi.asm.org/cgi/content/abstract/78/21/11656>

The chromosomal features that influence retroviral integration site selection are not well understood. Here, we report the mapping of 226 avian sarcoma virus (ASV) integration sites in the human genome. The results show that the sites are distributed over all chromosomes, and no global bias for integration site selection was detected. However, RNA polymerase II transcription units (protein-encoding genes) appear to be favored targets of ASV integration. The integration frequency within genes is similar to that previously described for murine leukemia virus but distinct from the higher frequency observed with human immunodeficiency virus type 1. We found no evidence for preferred ASV integration sites over the length of genes and immediate flanking regions. Microarray analysis of uninfected HeLa cells revealed that the expression levels of ASV target genes were similar to the median level for all genes represented in the array. Although expressed genes were targets for integration, we found no preference for integration into highly expressed genes. Our results provide a more detailed description of the chromosomal features that may influence ASV integration and support the idea that distinct, virus-specific mechanisms mediate integration site selection. Such differences may be relevant to viral pathogenesis and provide utility in retroviral vector design.

Oshima, M., D. Muriaux, et al. (2004). "Effects of Blocking Individual Maturation Cleavages in Murine Leukemia Virus Gag." *J. Virol.* **78**(3): 1411-1420.

<http://jvi.asm.org/cgi/content/abstract/78/3/1411>

A single protein, termed Gag, is responsible for retrovirus particle assembly. After the assembled virion is released from the cell, Gag is cleaved at several sites by the viral protease (PR). The cleavages catalyzed by PR bring about a wide variety of physical changes in the particle, collectively termed maturation, and convert the particle into an infectious virion. In murine leukemia virus (MLV) maturation, Gag is cleaved at three sites, resulting in formation of the matrix (MA), p12, capsid (CA), and nucleocapsid (NC) proteins. We introduced mutations into MLV that inhibited cleavage at individual sites in Gag. All mutants had lost the intensely staining ring characteristic of immature particles; thus, no single cleavage event is required for this feature of maturation. Mutant virions in which MA was not cleaved from p12 were still infectious, with a specific infectivity only [~]10-fold below that of the wild type. Particles in which p12 and CA could not be separated from each other were noninfectious and lacked a well-delineated core despite the presence of dense material in their interiors. In both of these mutants, the dimeric viral RNA had undergone the stabilization normally associated with maturation, suggesting that this change

may depend upon the separation of CA from NC. Alteration of the C-terminal end of CA blocked CA-NC cleavage but also reduced the efficiency of particle formation and, in some cases, severely disrupted the ability of Gag to assemble into regular structures. This observation highlights the critical role of this region of Gag in assembly.

Oster, B. and P. Hollsberg (2002). "Viral Gene Expression Patterns in Human Herpesvirus 6B-Infected T Cells." J. Virol. **76**(15): 7578-7586.

<http://jvi.asm.org/cgi/content/abstract/76/15/7578>

Herpesvirus gene expression is divided into immediate-early (IE) or {alpha} genes, early (E) or {beta} genes, and late (L) or {gamma} genes on the basis of temporal expression and dependency on other gene products. By using real-time PCR, we have investigated the expression of 35 human herpesvirus 6B (HHV-6B) genes in T cells infected by strain PL-1. Kinetic analysis and dependency on de novo protein synthesis and viral DNA polymerase activity suggest that the HHV-6B genes segregate into six separate kinetic groups. The genes expressed early (groups I and II) and late (groups V and VI) corresponded well with IE and L genes, whereas the intermediate groups III and IV contained E and L genes. Although HHV-6B has characteristics similar to those of other roseoloviruses in its overall gene regulation, we detected three B-variant-specific IE genes. Moreover, genes that were independent of de novo protein synthesis clustered in an area of the viral genome that has the lowest identity to the HHV-6A variant. The organization of IE genes in an area of the genome that differs from that of HHV-6A underscores the distinct differences between HHV-6B and HHV-6A and may provide a basis for further molecular and immunological analyses to elucidate their different biological behaviors.

Ozaki, H., E. A. Govorkova, et al. (2004). "Generation of High-Yielding Influenza A Viruses in African Green Monkey Kidney (Vero) Cells by Reverse Genetics." J. Virol. **78**(4): 1851-1857.

<http://jvi.asm.org/cgi/content/abstract/78/4/1851>

Influenza A viruses are the cause of annual epidemics of human disease with occasional outbreaks of pandemic proportions. The zoonotic nature of the disease and the vast viral reservoirs in the aquatic birds of the world mean that influenza will not easily be eradicated and that vaccines will continue to be needed. Recent technological advances in reverse genetics methods and limitations of the conventional production of vaccines by using eggs have led to a push to develop cell-based strategies to produce influenza vaccine. Although cell-based systems are being developed, barriers remain that need to be overcome if the potential of these systems is to be fully realized. These barriers include, but are not limited to, potentially poor reproducibility of viral rescue with reverse genetics systems and poor growth kinetics and yields. In this study we present a modified A/Puerto Rico/8/34 (PR8) influenza virus master strain that has improved viral rescue and growth properties in the African green monkey kidney cell line, Vero. The improved properties were mediated by the substitution of the PR8 NS gene for that of a Vero-adapted reassortant virus. The Vero growth kinetics of viruses with H1N1, H3N2, H6N1, and H9N2 hemagglutinin and neuraminidase combinations rescued on the new master strain were significantly enhanced in comparison to those of viruses with the same combinations rescued on the standard PR8 master strain. These improvements pave the way for the reproducible generation of high-yielding human and animal influenza vaccines by reverse genetics methods. Such a means of production has particular relevance to epidemic and pandemic use.

Ozbun, M. A. (2002). "Human Papillomavirus Type 31b Infection of Human Keratinocytes and the Onset of Early Transcription." J. Virol. **76**(22): 11291-11300.

<http://jvi.asm.org/cgi/content/abstract/76/22/11291>

Human papillomaviruses (HPVs) cause a number of human tumors and malignancies, including cervical cancers. Epithelial differentiation is required for the complete HPV life cycle and can be achieved using the organotypic (raft) culture system. The CIN-612 9E cell line maintains episomal copies of HPV type 31b (HPV31b), an HPV type associated with cervical cancers. When grown in the raft system, CIN-612 9E cells form a differentiated epithelium such that infectious virions can be synthesized. Many aspects of the later stages of the HPV31b life cycle have been investigated in CIN-612 9E raft tissues. We used a biologically contained homogenization system for efficient virion extraction from raft epithelial tissues. Purified HPV31b virions were used to infect low-passage-number human foreskin keratinocytes and a variety of epithelial cell lines. Newly synthesized, spliced HPV31b transcripts were detected by reverse transcription and PCR (RT-PCR) following HPV31b infection. HPV31b infection was most efficient and reproducible in HaCaT cells. The onset of viral transcription following infection was also investigated using RT-PCR techniques. Spliced E1*1, E2 RNAs were present as early as 4 h postinfection (p.i.), whereas the other major viral transcripts were detected by 8 to 10 h p.i. Furthermore, we characterized the structures and temporal expression of seven novel spliced early transcripts expressed following infection.

Payne, S. L., X.-f. Pei, et al. (2004). "Influence of Long Terminal Repeat and Env on the Virulence Phenotype of Equine Infectious Anemia Virus." J. Virol. **78**(5): 2478-2485.

<http://jvi.asm.org/cgi/content/abstract/78/5/2478>

The molecular clones pSPeIav19 and p19/wenv17 of equine infectious anemia virus (EIAV) differ in env and long terminal repeats (LTRs) and produce viruses (EIAV19 and EIAV17, respectively) of dramatically different virulence phenotypes. These constructs were used to generate a series of chimeric clones to test the individual contributions of LTR, surface (SU), and transmembrane (TM)/Rev regions to the disease potential of the highly virulent EIAV17. The LTRs of EIAV19 and EIAV17 differ by 16 nucleotides in the transcriptional enhancer region. The two viruses differ by 30 amino acids in SU, by 17 amino acids in TM, and by 8 amino acids in Rev. Results from in vivo infections with chimeric clones indicate that both LTR and env of EIAV17 are required for the development of severe acute disease. In the context of the EIAV17 LTR, SU appears to have a greater impact on virulence than does TM. EIAV17SU, containing only the TM/Rev region from the avirulent parent, induced acute disease in two animals, while a similar infectious dose of EIAV17TM (which derives SU from the avirulent parent) did not. Neither EIAV17SU nor EIAV17TM produced lethal disease when administered at infectious doses that were 6- to 30-fold higher than a lethal dose of the parental EIAV17. All chimeric clones replicated in primary equine monocyte-derived macrophages, and there was no apparent correlation between macrophage tropism and virulence phenotype.

Perez, D. R., W. Lim, et al. (2003). "Role of Quail in the Interspecies Transmission of H9 Influenza A Viruses: Molecular Changes on HA That Correspond to Adaptation from Ducks to Chickens." J. Virol. **77**(5): 3148-3156.

<http://jvi.asm.org/cgi/content/abstract/77/5/3148>

H9 influenza viruses have become endemic in land-based domestic poultry in Asia and have

sporadically crossed to pigs and humans. To understand the molecular determinants of their adaptation to land-based birds, we tested the replication and transmission of several 1970s duck H9 viruses in chickens and quail. Quail were more susceptible than chickens to these viruses, and generation of recombinant H9 viruses by reverse genetics showed that changes in the HA gene are sufficient to initiate efficient replication and transmission in quail. Seven amino acid positions on the HA molecule corresponded to adaptation to land-based birds. In quail H9 viruses, the pattern of amino acids at these seven positions is intermediate between those of duck and chicken viruses; this fact may explain the susceptibility of quail to duck H9 viruses. Our findings suggest that quail provide an environment in which the adaptation of influenza viruses from ducks generates novel variants that can cross the species barrier.

Poon, L. L. M., D. K. W. Chu, et al. (2005). "Identification of a Novel Coronavirus in Bats." J. Virol. **79**(4): 2001-2009.

<http://jvi.asm.org/cgi/content/abstract/79/4/2001>

Exotic wildlife can act as reservoirs of diseases that are endemic in the area or can be the source of new emerging diseases through interspecies transmission. The recent emergence of severe acute respiratory syndrome-associated coronavirus (SARS-CoV) highlights the importance of virus surveillance in wild animals. Here, we report the identification of a novel bat coronavirus through surveillance of coronaviruses in wildlife. Analyses of the RNA sequence from the ORF1b and S-gene regions indicated that the virus is a group 1 coronavirus. The virus was detected in fecal and respiratory samples from three bat species (*Miniopterus* spp.). In particular, 63% (12 of 19) of fecal samples from *Miniopterus pusillus* were positive for the virus. These findings suggest that this virus might be commonly circulating in *M. pusillus* in Hong Kong.

Roca, A. L., W. G. Nash, et al. (2005). "Insertional Polymorphisms of Endogenous Feline Leukemia Viruses." J. Virol. **79**(7): 3979-3986.

<http://jvi.asm.org/cgi/content/abstract/79/7/3979>

The number, chromosomal distribution, and insertional polymorphisms of endogenous feline leukemia viruses (enFeLVs) were determined in four domestic cats (Burmese, Egyptian Mau, Persian, and nonbreed) using fluorescent in situ hybridization and radiation hybrid mapping. Twenty-nine distinct enFeLV loci were detected across 12 of the 18 autosomes. Each cat carried enFeLV at only 9 to 16 of the loci, and many loci were heterozygous for presence of the provirus. Thus, an average of 19 autosomal copies of enFeLV were present per cat diploid genome. Only five of the autosomal enFeLV sites were present in all four cats, and at only one autosomal locus, B4q15, was enFeLV present in both homologues of all four cats. A single enFeLV occurred in the X chromosome of the Burmese cat, while three to five enFeLV proviruses occurred in each Y chromosome. The X chromosome and nine autosomal enFeLV loci were telomeric, suggesting that ectopic recombination between nonhomologous subtelomeres may contribute to enFeLV distribution. Since endogenous FeLVs may affect the infectiousness or pathogenicity of exogenous FeLVs, genomic variation in enFeLVs represents a candidate for genetic influences on FeLV leukemogenesis in cats.

Rohayem, J., J. Munch, et al. (2005). "Evidence of Recombination in the Norovirus Capsid Gene." J. Virol. **79**(8): 4977-4990.

<http://jvi.asm.org/cgi/content/abstract/79/8/4977>

Noroviruses are single-stranded RNA viruses with high genomic variability. They have emerged in the last decade as a major cause of acute gastroenteritis. It remains so far unclear whether norovirus evolution is driven by sequence mutation and/or recombination. In this study, we have assessed the occurrence of recombination in the norovirus capsid gene. For this purpose, 69 complete capsid sequences of norovirus strains accessible in GenBank as well as 25 complete capsid sequences generated from norovirus-positive clinical samples were examined. Unreported recombination was detected in about 8% of norovirus strains belonging to genetic clusters I/1 (n = 1), II/1 (n = 1), II/3 (n = 1), II/4 (n = 3), and II/5 (n = 1). Recombination breakpoints were mainly located at the interface of the putative P1-1 and P2 domains of the capsid protein and/or within the P2 domain. The recombination region displayed features such as length, sequence composition (upstream and downstream GC- and AU-rich sequences, respectively), and predicted RNA secondary structure that are characteristic of homologous recombination activators. Our results suggest that recombination in the norovirus capsid gene may naturally occur, involving capsid domains presumably exposed to immunological pressure.

Roque-Afonso, A.-M., D. Ducoulombier, et al. (2005). "Compartmentalization of Hepatitis C Virus Genotypes between Plasma and Peripheral Blood Mononuclear Cells." *J. Virol.* **79**(10): 6349-6357.

<http://jvi.asm.org/cgi/content/abstract/79/10/6349>

Differences in hepatitis C virus (HCV) variants of the highly conserved 5' untranslated region (UTR) have been observed between plasma and peripheral blood mononuclear cells (PBMC). The prevalence and the mechanisms of this compartmentalization are unknown. Plasma and PBMC HCV variants were compared by single-strand conformation polymorphism (SSCP) and by cloning or by genotyping with a line probe assay (LiPA) in 116 chronically infected patients, including 44 liver transplant recipients. SSCP patterns differed between compartments in 43/109 analyzable patients (39%). Differences were significantly more frequent in patients with transplants (21/38 [55%] versus 22/71 [31%]; $P < 0.01$) and in those who acquired HCV through multiple transfusions before 1991 (15/20; 75%) or through drug injection (16/31; 52%) than in those infected through an unknown route (7/29; 24%) or through a single transfusion (5/29; 17%; $P < 0.001$). Cloning of the 5' UTR, LiPA analysis, and nonstructural region 5B sequencing revealed different genotypes in the two compartments from 10 patients (9%). In nine patients, the genotype detected in PBMC was not detected in plasma and was weak or undetectable in the liver in three cases. This genotypic compartmentalization persisted for years in three patients and after liver transplantation in two. The present study shows that a significant proportion of HCV-infected subjects harbor in their PBMC highly divergent variants which were likely acquired through superinfections.

Rose, T. M., J. T. Ryan, et al. (2003). "Analysis of 4.3 Kilobases of Divergent Locus B of Macaque Retroperitoneal Fibromatosis-Associated Herpesvirus Reveals a Close Similarity in Gene Sequence and Genome Organization to Kaposi's Sarcoma-Associated Herpesvirus." *J. Virol.* **77**(9): 5084-5097.

<http://jvi.asm.org/cgi/content/abstract/77/9/5084>

We previously identified retroperitoneal fibromatosis-associated herpesvirus (RFHV) as a simian homolog of Kaposi's sarcoma-associated herpesvirus (KSHV) in a fibroproliferative malignancy of macaques that has similarities to Kaposi's sarcoma. In this report, we cloned 4.3 kb of divergent

locus B (DL-B) flanking the DNA polymerase gene from two variants of RFHV from different species of macaque with a consensus degenerate hybrid oligonucleotide primer approach. Within the DL-B region of RFHV, viral homologs of the cellular interleukin-6, dihydrofolate reductase, and thymidylate synthase genes were identified, along with a homolog of the gammaherpesvirus open reading frame (ORF) 10. In addition, a homolog of the KSHV ORF K3, the modulator of immune recognition-1, was identified. Our data show a close similarity in sequence conservation, gene content, and genomic structure between RFHV and KSHV which strongly supports the grouping of these viral species within the same RV-1 rhadinovirus lineage and the hypothesis that RFHV is the macaque homolog of KSHV.

Roux, M. M., A. Pain, et al. (2002). "The Lipopolysaccharide and {beta}-1,3-Glucan Binding Protein Gene Is Upregulated in White Spot Virus-Infected Shrimp (*Penaeus stylirostris*)."
J. Virol. **76**(14): 7140-7149.

<http://jvi.asm.org/cgi/content/abstract/76/14/7140>

Pattern recognition proteins such as lipopolysaccharide and {beta}-1,3-glucan binding protein (LGBP) play an important role in the innate immune response of crustaceans and insects. Random sequencing of cDNA clones from a hepatopancreas cDNA library of white spot virus (WSV)-infected shrimp provided a partial cDNA (PsEST-289) that showed similarity to the LGBP gene of crayfish and insects. Subsequently full-length cDNA was cloned by the 5'-RACE (rapid amplification of cDNA ends) technique and sequenced. The shrimp LGBP gene is 1,352 bases in length and is capable of encoding a polypeptide of 376 amino acids that showed significant similarity to homologous genes from crayfish, insects, earthworms, and sea urchins. Analysis of the shrimp LGBP deduced amino acid sequence identified conserved features of this gene family including a potential recognition motif for {beta}-(1->3) linkage of polysaccharides and putative RGD cell adhesion sites. It is known that LGBP gene expression is upregulated in bacterial and fungal infection and that the binding of lipopolysaccharide and {beta}-1,3-glucan to LGBP activates the prophenoloxidase (proPO) cascade. The temporal expression of LGBP and proPO genes in healthy and WSV-challenged *Penaeus stylirostris* shrimp was measured by real-time quantitative reverse transcription-PCR, and we showed that LGBP gene expression in shrimp was upregulated as the WSV infection progressed. Interestingly, the proPO expression was upregulated initially after infection followed by a downregulation as the viral infection progressed. The downward trend in the expression of proPO coincided with the detection of WSV in the infected shrimp. Our data suggest that shrimp LGBP is an inducible acute-phase protein that may play a critical role in shrimp-WSV interaction and that the WSV infection regulates the activation and/or activity of the proPO cascade in a novel way.

Rovira, A., M. Balasch, et al. (2002). "Experimental Inoculation of Conventional Pigs with Porcine Reproductive and Respiratory Syndrome Virus and Porcine Circovirus 2." *J. Virol.* **76**(7): 3232-3239.

<http://jvi.asm.org/cgi/content/abstract/76/7/3232>

Postweaning multisystemic wasting syndrome (PMWS) is a disease of nursery and fattening pigs characterized by growth retardation, paleness of the skin, dyspnea, and increased mortality rates. Porcine circovirus 2 (PCV2) has been demonstrated to be the cause of PMWS. However, other factors are needed for full development of the syndrome, and porcine reproductive and respiratory syndrome virus (PRRSV) infection has been suggested to be one of them. Twenty-four conventional 5-week-old pigs were distributed in four groups: control (n = 5), PRRSV inoculated (n = 5), PCV2 inoculated (n = 7), and PRRSV and PCV2 inoculated (n = 7). The two groups inoculated with PRRSV showed growth retardation. Pigs inoculated with both PRRSV and

PCV2 had increased rectal temperature. One of these pigs developed wasting, had severe respiratory distress, and died. The most important microscopic lesion in pigs inoculated with PCV2 was lymphocyte depletion with histiocytic infiltration of the lymphoid organs, more severe and in a wider range of tissues in doubly inoculated pigs. Interstitial pneumonia was observed in the three inoculated groups. PCV2 nucleic acid was found by in situ hybridization in larger amounts and in a wider range of lymphoid tissues in PRRSV- and PCV2-inoculated than in PCV2-inoculated pigs. TaqMan PCR was performed to quantify the PCV2 loads in serum during the experiment. PCV2 loads were higher in doubly inoculated pigs than in pigs inoculated with PCV2 alone. These findings indicate that severe disease can be reproduced in conventional 5-week-old pigs by inoculation of PRRSV and PCV2. Moreover, these results support the hypothesis that PRRSV infection enhances PCV2 replication.

Schafer, A., D. Lengenfelder, et al. (2003). "The Latency-Associated Nuclear Antigen Homolog of Herpesvirus Saimiri Inhibits Lytic Virus Replication." *J. Virol.* **77**(10): 5911-5925.

<http://jvi.asm.org/cgi/content/abstract/77/10/5911>

Herpesvirus saimiri (HVS), a T-lymphotropic tumor virus of neotropical primates, and the Kaposi's sarcoma-associated human herpesvirus 8 (KSHV) belong to the gamma-2-herpesvirus (Rhadinovirus) subfamily and share numerous features of genome structure and organization. The KSHV latency-associated nuclear antigen (LANA) protein appears to be relevant for viral persistence, latency, and transformation. It binds to DNA, colocalizes with viral episomal DNA, and presumably mediates efficient persistence of viral genomes. LANA further represses the transcriptional and proapoptotic activities of the p53 tumor suppressor protein. Here we report on the ORF73 gene of HVS strain C488, which is the positional and structural homolog of KSHV LANA. The ORF73 gene in OMK cells can encode a 62-kDa protein that localizes to the nucleus in a pattern similar to that of LANA. We show that the ORF73 gene product can regulate viral gene expression by acting as a transcriptional modulator of latent and lytic viral promoters. To define the HVS ORF73 function in the background of a replication-competent virus, we constructed a viral mutant that expresses ORF73 under the transcriptional control of a mifepristone (RU-486)-inducible promoter. The HVS ORF73 gene product efficiently suppresses lytic viral replication in permissive cells, indicating that it defines a critical control point between viral persistence and lytic replication.

Scholtissek, C., J. Stech, et al. (2002). "Cooperation between the Hemagglutinin of Avian Viruses and the Matrix Protein of Human Influenza A Viruses." *J. Virol.* **76**(4): 1781-1786.

<http://jvi.asm.org/cgi/content/abstract/76/4/1781>

To analyze the compatibility of avian influenza A virus hemagglutinins (HAs) and human influenza A virus matrix (M) proteins M1 and M2, we doubly infected Madin-Darby canine kidney cells with amantadine (1-aminoadamantane hydrochloride)-resistant human viruses and amantadine-sensitive avian strains. By using antisera against the human virus HAs and amantadine, we selected reassortants containing the human virus M gene and the avian virus HA gene. In our system, high virus yields and large, well-defined plaques indicated that the avian HAs and the human M gene products could cooperate effectively; low virus yields and small, turbid plaques indicated that cooperation was poor. The M gene products are among the primary components that determine the species specificities of influenza A viruses. Therefore, our system also indicated whether the avian HA genes effectively reassorted into the genome and replaced the HA gene of the prevailing human influenza A viruses. Most of the avian HAs that we tested efficiently cooperated with the M gene products of the early human A/PR/8/34 (H1N1) virus; however, the avian HAs did not effectively cooperate with the most recently isolated human virus

that we tested, A/Nanchang/933/95 (H3N2). Cooperation between the avian HAs and the M proteins of the human A/Singapore/57 (H2N2) virus was moderate. These results suggest that the currently prevailing human influenza A viruses might have lost their ability to undergo antigenic shift and therefore are unable to form new pandemic viruses that contain an avian HA, a finding that is of great interest for pandemic planning.

Scobie, L., S. Taylor, et al. (2004). "Absence of Replication-Competent Human-Tropic Porcine Endogenous Retroviruses in the Germ Line DNA of Inbred Miniature Swine." *J. Virol.* **78**(5): 2502-2509.

<http://jvi.asm.org/cgi/content/abstract/78/5/2502>

The potential transmission of porcine endogenous retroviruses (PERVs) has raised concern in the development of porcine xenotransplantation products. Our previous studies have resulted in the identification of animals within a research herd of inbred miniature swine that lack the capacity to transmit PERV to human cells in vitro. In contrast, other animals were capable of PERV transmission. The PERVs that were transmitted to human cells are recombinants between PERV-A and PERV-C in the post-VRA region of the envelope (B. A. Oldmixon, J. C. Wood, T. A. Ericsson, C. A. Wilson, M. E. White-Scharf, G. Andersson, J. L. Greenstein, H. J. Schuurman, and C. Patience, *J. Virol.* 76:3045-3048, 2002); these viruses we term PERV-A/C. This observation prompted us to determine whether these human-tropic replication-competent (HTRC) PERV-A/C recombinants were present in the genomic DNA of these miniature swine. Genomic DNA libraries were generated from one miniature swine that transmitted HTRC PERV as well as from one miniature swine that did not transmit HTRC PERV. HTRC PERV-A/C proviruses were not identified in the germ line DNAs of these pigs by using genomic mapping. Similarly, although PERV-A loci were identified in both libraries that possessed long env open reading frames, the Env proteins encoded by these loci were nonfunctional according to pseudotype assays. In the absence of a germ line source for HTRC PERV, further studies are warranted to assess the mechanisms by which HTRC PERV can be generated. Once identified, it may prove possible to generate animals with further reduced potential to produce HTRC PERV.

Silverman, L. R., A. J. Phipps, et al. (2004). "Human T-Cell Lymphotropic Virus Type 1 Open Reading Frame II-Encoded p30II Is Required for In Vivo Replication: Evidence of In Vivo Reversion." *J. Virol.* **78**(8): 3837-3845.

<http://jvi.asm.org/cgi/content/abstract/78/8/3837>

Human T-cell lymphotropic virus type 1 (HTLV-1) causes adult T-cell leukemia/lymphoma and exhibits high genetic stability in vivo. HTLV-1 contains four open reading frames (ORFs) in its pX region. ORF II encodes two proteins, p30II and p13II, both of which are incompletely characterized. p30II localizes to the nucleus or nucleolus and has distant homology to the transcription factors Oct-1, Pit-1, and POU-M1. In vitro studies have demonstrated that at low concentrations, p30II differentially regulates cellular and viral promoters through an interaction with CREB binding protein/p300. To determine the in vivo significance of p30II, we inoculated rabbits with cell lines expressing either a wild-type clone of HTLV-1 (ACH.1) or a clone containing a mutation in ORF II, which eliminated wild-type p30II expression (ACH.30.1). ACH.1-inoculated rabbits maintained higher HTLV-1-specific antibody titers than ACH.30.1-inoculated rabbits, and all ACH.1-inoculated rabbits were seropositive for HTLV-1, whereas only two of six ACH.30.1-inoculated rabbits were seropositive. Provirus could be consistently PCR amplified from peripheral blood mononuclear cell (PBMC) DNA in all ACH.1-inoculated rabbits but in only three of six ACH.30.1-inoculated rabbits. Quantitative competitive PCR indicated higher PBMC proviral loads in ACH.1-inoculated rabbits. Interestingly, sequencing of ORF II from PBMC of provirus-

positive ACH.30.1-inoculated rabbits revealed a reversion to wild-type sequence with evidence of early coexistence of mutant and wild-type sequence. Our data provide evidence that HTLV-1 must maintain its key accessory genes to survive in vivo and that in vivo pressures select for maintenance of wild-type ORF II gene products during the early course of infection.

Silvestri, G., A. Fedanov, et al. (2005). "Divergent Host Responses during Primary Simian Immunodeficiency Virus SIVsm Infection of Natural Sooty Mangabey and Nonnatural Rhesus Macaque Hosts." *J. Virol.* **79**(7): 4043-4054.

<http://jvi.asm.org/cgi/content/abstract/79/7/4043>

To understand how natural sooty mangabey hosts avoid AIDS despite high levels of simian immunodeficiency virus (SIV) SIVsm replication, we inoculated mangabeys and nonnatural rhesus macaque hosts with an identical inoculum of uncloned SIVsm. The unpassaged virus established infection with high-level viral replication in both macaques and mangabeys. A species-specific, divergent immune response to SIV was evident from the first days of infection and maintained in the chronic phase, with macaques showing immediate and persistent T-cell proliferation, whereas mangabeys displayed little T-cell proliferation, suggesting subdued cellular immune responses to SIV. Importantly, only macaques developed CD4+-T-cell depletion and AIDS, thus indicating that in mangabeys limited immune activation is a key mechanism to avoid immunodeficiency despite high levels of SIVsm replication. These studies demonstrate that it is the host response to infection, rather than properties inherent to the virus itself, that causes immunodeficiency in SIV-infected nonhuman primates.

Sitki-Green, D., M. Covington, et al. (2003). "Compartmentalization and Transmission of Multiple Epstein-Barr Virus Strains in Asymptomatic Carriers." *J. Virol.* **77**(3): 1840-1847.

<http://jvi.asm.org/cgi/content/abstract/77/3/1840>

Infection with the Epstein-Barr virus (EBV) is often subclinical in the presence of a healthy immune response; thus, asymptomatic infection is largely uncharacterized. This study analyzed the nature of EBV infection in 20 asymptomatic immunocompetent hosts over time through the identification of EBV strain variants in the peripheral blood and oral cavity. A heteroduplex tracking assay specific for the EBV gene LMP1 precisely identified the presence of multiple EBV strains in each subject. The strains present in the peripheral blood and oral cavity were often completely discordant, indicating the existence of distinct infections, and the strains present and their relative abundance changed considerably between time points. The possible transmission of strains between the oral cavity and peripheral blood compartments could be tracked within subjects, suggesting that reactivation in the oral cavity and subsequent reinfection of B lymphocytes that reenter the periphery contribute to the maintenance of persistence. In addition, distinct virus strains persisted in the oral cavity over many time points, suggesting an important role for epithelial cells in the maintenance of persistence. Asymptomatic individuals without tonsillar tissue, which is believed to be an important source of virus for the oral cavity, also exhibited multiple strains and a cyclic pattern of transmission between compartments. This study revealed that the majority of patients with infectious mononucleosis were infected with multiple strains of EBV that were also compartmentalized, suggesting that primary infection involves the transmission of multiple strains. Both the primary and carrier states of infection with EBV are more complex than previously thought.

Sitki-Green, D., R. H. Edwards, et al. (2002). "Identification of Epstein-Barr Virus Strain Variants in Hairy Leukoplakia and Peripheral Blood by Use of a Heteroduplex Tracking Assay." J. Virol. **76**(19): 9645-9656.

<http://jvi.asm.org/cgi/content/abstract/76/19/9645>

Epstein-Barr virus (EBV) strains can be distinguished by specific sequence variations in the LMP1 gene. In this study, a heteroduplex tracking assay (HTA) specific for LMP1 was developed to precisely identify the prototypic undeleted strain B958, other undeleted strains (Ch2, AL, NC, and Med-), and strains with the 30-bp deletion (Med+ and Ch1). This technique also provides an estimate of the relative abundance of strains in patient samples. In this study, EBV strains were identified in 25 hairy leukoplakia (HLP) biopsies and six matched peripheral blood samples and throat washes with the LMP1-HTA. To investigate the relationship of the virus found in the peripheral blood to that in the HLP lesion, the strain variants in the peripheral blood B lymphocytes and those present within the epithelial cells in the HLP lesion and in throat washes were identified. In many of the subjects, compartmental differences in the EBV strain profiles in the oral cavity and peripheral blood were readily apparent. The throat wash specimens usually had a strain profile similar to that within the corresponding HLP sample, which was distinct from the strain profile detected in the peripheral blood. These analyses reveal that the nature of EBV infection can be very dynamic, with changes in relative strain abundance over time as well as the appearance of new strains. The patterns of abundance in the blood and oral cavity provide evidence for compartmentalization and for the transmission of strains between the blood and oropharynx.

Smith, M. Z., C. J. Dale, et al. (2005). "Analysis of Pigtail Macaque Major Histocompatibility Complex Class I Molecules Presenting Immunodominant Simian Immunodeficiency Virus Epitopes." J. Virol. **79**(2): 684-695.

<http://jvi.asm.org/cgi/content/abstract/79/2/684>

Successful human immunodeficiency virus (HIV) vaccines will need to induce effective T-cell immunity. We studied immunodominant simian immunodeficiency virus (SIV) Gag-specific T-cell responses and their restricting major histocompatibility complex (MHC) class I alleles in pigtail macaques (*Macaca nemestrina*), an increasingly common primate model for the study of HIV infection of humans. CD8⁺ T-cell responses to an SIV epitope, Gag164-172KP9, were present in at least 15 of 36 outbred pigtail macaques. The immunodominant KP9-specific response accounted for the majority (mean, 63%) of the SIV Gag response. Sequencing from six macaques identified 7 new Mane-A and 13 new Mane-B MHC class I alleles. One new allele, Mane-A*10, was common to four macaques that responded to the KP9 epitope. We adapted reference strand-mediated conformational analysis (RSCA) to MHC class I genotype *M. nemestrina*. Mane-A*10 was detected in macaques presenting KP9 studied by RSCA but was absent from non-KP9-presenting macaques. Expressed on class I-deficient cells, Mane-A*10, but not other pigtail macaque MHC class I molecules, efficiently presented KP9 to responder T cells, confirming that Mane-A*10 restricts the KP9 epitope. Importantly, naive pigtail macaques infected with SIVmac251 that respond to KP9 had significantly reduced plasma SIV viral levels (log₁₀ 0.87 copies/ml; *P* = 0.025) compared to those of macaques not responding to KP9. The identification of this common *M. nemestrina* MHC class I allele restricting a functionally important immunodominant SIV Gag epitope establishes a basis for studying CD8⁺ T-cell responses against AIDS in an important, widely available nonhuman primate species.

Stadnick, E., M. Dan, et al. (2004). "Attenuating Mutations in Coxsackievirus B3 Map to a Conformational Epitope That Comprises the Puff Region of VP2 and the Knob of VP3." J. Virol. **78**(24): 13987-

14002.

<http://jvi.asm.org/cgi/content/abstract/78/24/13987>

Ten antibody escape mutants of coxsackievirus B3 (CVB3) were used to identify nucleotide substitutions that determine viral virulence for the heart and pancreas. The P1 region, encoding the structural genes of each mutant, was sequenced to identify mutations associated with the lack of neutralization. Eight mutants were found to have a lysine-to arginine mutation in the puff region of VP2, while two had a glutamate-to-glycine substitution in the knob of VP3. Two mutants, EM1 and EM10, representing each of these mutations, were further analyzed, initially by determining their entire sequence. In addition to the mutations in P1, EM1 was found to have two mutations in the 3D polymerase, while EM10 had a mutation in stem-loop II of the 5' nontranslated region (5'NTR). The pathogenesis of the mutants relative to that of CVB3 strain RK [CVB3(RK)] then was examined in A/J mice. Both mutants were found to be less cardiotropic than the parental strain, with a 40-fold (EM1) or a 100- to 1,000-fold (EM10) reduction in viral titers in the heart relative to the titers of CVB3(RK). The mutations in VP2, VP3, and the 5'NTR were introduced independently into the RK infectious clone, and the phenotypes of the progeny viruses were determined. The results substantiated that the VP2 and VP3 mutations reduced cardiovirulence, while the 5'NTR mutation in EM10 was associated with a more virulent phenotype when expressed on its own. Stereographic imaging of the two mutations in the capsomer showed that they lie in close proximity on either side of a narrow cleft between the puff and the knob, forming a conformational epitope that is part of the putative binding site for coreceptor DAF.

Stonebraker, J. R., D. Wagner, et al. (2004). "Glycocalyx Restricts Adenoviral Vector Access to Apical Receptors Expressed on Respiratory Epithelium In Vitro and In Vivo: Role for Tethered Mucins as Barriers to Luminal Infection." J. Virol. **78**(24): 13755-13768.

<http://jvi.asm.org/cgi/content/abstract/78/24/13755>

Inefficient adenoviral vector (AdV)-mediated gene transfer to the ciliated respiratory epithelium has hindered gene transfer strategies for the treatment of cystic fibrosis lung disease. In part, the inefficiency is due to an absence of the coxsackie B and adenovirus type 2 and 5 receptor (CAR) from the apical membranes of polarized epithelia. In this study, using an in vitro model of human ciliated airway epithelium, we show that providing a glycosylphosphatidylinositol (GPI)-linked AdV receptor (GPI-CAR) at the apical surface did not significantly improve AdV gene transfer efficiency because the luminal surface glycocalyx limited the access of AdV to apical GPI-CAR. The highly glycosylated tethered mucins were considered to be significant glycocalyx components that restricted AdV access because proteolytic digestion and inhibitors of O-linked glycosylation enhanced AdV gene transfer. To determine whether these in vitro observations are relevant to the in vivo situation, we generated transgenic mice expressing GPI-CAR at the surface of the airway epithelium, crossbred these mice with mice that were genetically devoid of tethered mucin type 1 (Muc1), and tested the efficiency of gene transfer to murine airways expressing apical GPI-human CAR (GPI-hCAR) in the presence and absence of Muc1. We determined that AdV gene transfer to the murine airway epithelium was inefficient even in GPI-hCAR transgenic mice but that the gene transfer efficiency improved in the absence of Muc1. However, the inability to achieve a high gene transfer efficiency, even in mice with a deletion of Muc1, suggested that other glycocalyx components, possibly other tethered mucin types, also provide a significant barrier to AdV interacting with the airway luminal surface.

Streblow, D. N., C. Kreklywich, et al. (2003). "Cytomegalovirus-Mediated Upregulation of Chemokine Expression Correlates with the Acceleration of Chronic Rejection in Rat Heart Transplants." J. Virol. **77**(3): 2182-2194.

<http://jvi.asm.org/cgi/content/abstract/77/3/2182>

Cytomegalovirus (CMV) infections have been shown to dramatically affect solid organ transplant graft survival in both human and animal models. Recently, it was demonstrated that rat CMV (RCMV) infection accelerates the development of transplant vascular sclerosis (TVS) in both rat heart and small bowel graft transplants. However, the mechanisms involved in this process are still unclear. In the present study, we determined the kinetics of RCMV-accelerated TVS in a rat heart transplant model. Acute RCMV infection enhances the development of TVS in rat heart allografts, and this process is initiated between 21 and 24 days posttransplantation. The virus is consistently detected in the heart grafts from day 7 until day 35 posttransplantation but is rarely found at the time of graft rejection (day 45 posttransplantation). Grafts from RCMV-infected recipients had upregulation of chemokine expression compared to uninfected controls, and the timing of this increased expression paralleled that of RCMV-accelerated neointimal formation. In addition, graft vessels from RCMV-infected grafts demonstrate the increased infiltration of T cells and macrophages during periods of highest chemokine expression. These results suggest that CMV-induced acceleration of TVS involves the increased graft vascular infiltration of inflammatory cells through enhanced chemokine expression.

Sung, V. M. H., S. Shimodaira, et al. (2003). "Establishment of B-Cell Lymphoma Cell Lines Persistently Infected with Hepatitis C Virus In Vivo and In Vitro: the Apoptotic Effects of Virus Infection." J. Virol. **77**(3): 2134-2146.

<http://jvi.asm.org/cgi/content/abstract/77/3/2134>

Hepatitis C virus (HCV) is a major cause of chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma. Studies of HCV replication and pathogenesis have so far been hampered by the lack of an efficient tissue culture system for propagating HCV in vitro. Although HCV is primarily a hepatotropic virus, an increasing body of evidence suggests that HCV also replicates in extrahepatic tissues in natural infection. In this study, we established a B-cell line (SB) from an HCV-infected non-Hodgkin's B-cell lymphoma. HCV RNA and proteins were detectable by RNase protection assay and immunoblotting. The cell line continuously produces infectious HCV virions in culture. The virus particles produced from the culture had a buoyant density of 1.13 to 1.15 g/ml in sucrose and could infect primary human hepatocytes, peripheral blood mononuclear cells (PBMCs), and an established B-cell line (Raji cells) in vitro. The virus from SB cells belongs to genotype 2b. Single-stranded conformational polymorphism and sequence analysis of the viral RNA quasispecies indicated that the virus present in SB cells most likely originated from the patient's spleen and had an HCV RNA quasispecies pattern distinct from that in the serum. The virus production from the infected primary hepatocytes showed cyclic variations. In addition, we have succeeded in establishing several Epstein-Barr virus-immortalized B-cell lines from PBMCs of HCV-positive patients. Two of these cell lines are positive for HCV RNA as detected by reverse transcriptase PCR and for the nonstructural protein NS3 by immunofluorescence staining. These observations unequivocally establish that HCV infects B cells in vivo and in vitro. HCV-infected cell lines show significantly enhanced apoptosis. These B-cell lines provide a reproducible cell culture system for studying the complete replication cycle and biology of HCV infections.

Suzuki, N. and D. L. Nuss (2002). "Contribution of Protein p40 to Hypovirus-Mediated Modulation of Fungal Host Phenotype and Viral RNA Accumulation." J. Virol. **76**(15): 7747-7759.

<http://jvi.asm.org/cgi/content/abstract/76/15/7747>

The papain-like protease p29, derived from the N-terminal portion of the hypovirus CHV1-EP713-

encoded open reading frame (ORF) A polyprotein, p69, was previously shown to contribute to reduced pigmentation and sporulation by the infected host, the chestnut blight fungus *Cryphonectria parasitica*, while being dispensable for virus replication and attenuation of fungal virulence (hypovirulence). We now report that deletion of the C-terminal portion of p69, which encodes the highly basic protein p40, resulted in replication-competent mutant viruses that were, however, significantly reduced in RNA accumulation. While the Δ p40 mutants retained the ability to confer hypovirulence, Δ p40-infected fungal strains produced more asexual spores than strains infected with either wild-type CHV1-EP713 or a Δ p29 mutant virus. As observed for Δ p29-infected colonies, pigment production was significantly increased in Δ p40-infected fungal strains relative to that in CHV1-EP713-infected strains. Virus-mediated suppression of laccase production was not affected by p40 deletion. A gain-of-function analysis was employed to map the p40 symptom determinant to the N-terminal domain, encompassing p69 amino acid residues Thr(288) to Arg(312). Evidence that the gain of function was due to the encoded protein rather than the corresponding RNA sequence element was provided by introducing frameshift mutations on either side of the activity determinant domain. Moreover, restoration of symptoms correlated with increased accumulation of viral RNA. These results suggest that p40 indirectly contributes to virus-mediated suppression of fungal pigmentation and conidiation by providing an accessory function in hypovirus RNA amplification. A possible role for p40 in facilitating ORF B expression and the relationship between hypovirus RNA accumulation and symptom expression are discussed.

Taddeo, B., A. Esclatine, et al. (2003). "The Stress-Inducible Immediate-Early Responsive Gene IEX-1 Is Activated in Cells Infected with Herpes Simplex Virus 1, but Several Viral Mechanisms, Including 3' Degradation of Its RNA, Preclude Expression of the Gene." *J. Virol.* **77**(11): 6178-6187.

<http://jvi.asm.org/cgi/content/abstract/77/11/6178>

The accumulation of cellular transcripts from cells infected with herpes simplex virus 1 (HSV-1) as measured with the aid of Affymetrix microchips has been reported elsewhere. Among these transcripts were genes that respond to stress and that could have a noxious effect on viral replication. We have selected the stress-inducible cellular gene encoding the immediate-early response protein IEX-1 to verify and determine the significance of the accumulation of these transcripts in infected cells. We report that we verified the increase in accumulation of IEX-1 transcripts after infection by Northern analyses and real-time PCR. These transcripts reach peak levels between 3 and 7 h after infection and decrease thereafter. However, IEX-1 protein was detected in cells 1 h after infection but not at later intervals. Studies designed to elucidate the failure of IEX-1 protein to be synthesized revealed the following points. (i) IEX-1 RNA transported to the cytoplasm after 1 h of infection consisted of at least two populations, a partially degraded population and a population consisting of unspliced IEX-1 RNA. Neither of these RNAs could translate the authentic IEX-1 protein. (ii) The partially degraded IEX-1 RNA was not detected in the cytoplasm of cells infected with a mutant virus lacking the UL41 gene encoding the virion host shutoff protein (vhs). Although degradation of RNA mediated by vhs was reported to be 5' to 3', the partially degraded IEX-1 RNA lacked the 3' sequences rather than the 5' sequences. (iii) The unspliced pre-RNA form containing the IEX-1 intron sequences was detected in the cytoplasm of cell infected with wild-type virus but not in those infected with a mutant lacking the α 27 gene encoding the infected cell protein No. 27. (iv) Overexpression of IEX-1 protein by transduction of the gene prior to infection with 1 PFU of HSV-1 per cell had no effect on the accumulation of late genes and virus yield. We conclude that the failure of IEX-1 to express its protein reflects the numerous mechanisms by which the virus thwarts the cells from expressing its genes after infection.

Taddeo, B., W. Zhang, et al. (2004). "Cells Lacking NF- κ B or in Which NF- κ B Is Not

Activated Vary with Respect to Ability To Sustain Herpes Simplex Virus 1 Replication and Are Not Susceptible to Apoptosis Induced by a Replication-Incompetent Mutant Virus." *J. Virol.* **78**(21): 11615-11621.

<http://jvi.asm.org/cgi/content/abstract/78/21/11615>

Earlier we reported that NF- κ B is activated by protein kinase R (PKR) in herpes simplex virus 1-infected cells. Here we report that in PKR $^{-/-}$ cells the yields of wild-type virus are 10-fold higher than in PKR $^{+/+}$ cells. In cells lacking NF- κ B p50 (nfb1), p65 (relA), or both p50 and p65, the yields of virus were reduced 10-fold. Neither wild-type nor mutant cells undergo apoptosis following infection with wild-type virus. Whereas PKR $^{+/+}$ and NF- κ B $^{+/+}$ control cell lines undergo apoptosis induced by the d120 ($\Delta\alpha$ 4) mutant of HSV-1, the mutant PKR $^{-/-}$ and NF- κ B $^{-/-}$ cell lines were resistant. The evidence suggests that the stress-induced apoptosis resulting from d120 infection requires activation of NF- κ B and that this proapoptotic pathway is blocked in cells in which NF- κ B is not activated or absent. Activation of NF- κ B in the course of viral infection may have dual roles of attempting to curtail viral replication by rendering the cell susceptible to apoptosis induced by the virus and by inducing the synthesis of proteins that enhance viral replication.

Tam, P. E., M. L. Weber-Sanders, et al. (2003). "Multiple Viral Determinants Mediate Myopathogenicity in Coxsackievirus B1-Induced Chronic Inflammatory Myopathy." *J. Virol.* **77**(21): 11849-11854.

<http://jvi.asm.org/cgi/content/abstract/77/21/11849>

Mice infected with myopathic coxsackievirus B1 Tucson (CVB1T) develop chronic inflammatory myopathy (CIM) consisting of hind limb weakness and inflammation. Amyopathic virus variants are infectious but attenuated for CIM. In this report, viral clones, chimeras, and sequencing were used to identify viral determinants of CIM. Chimeras identified several regions involved in CIM and localized a weakness determinant to nucleotides 2493 to 3200 of VP1. Sequencing of multiple clones and viruses identified five candidate determinants that were strictly conserved in myopathic viruses with one located in the 5' untranslated region (UTR), three in the VP1 capsid, and one in the 3C protease. Taken together, these studies implicate Tyr-87 and/or Val-136 as candidate determinants of weakness. They also indicate that there are at least two determinants of inflammation and one additional determinant of weakness encoded by myopathic CVB1T.

Tang, Y., F. Villinger, et al. (2002). "Slowly Declining Levels of Viral RNA and DNA in DNA/Recombinant Modified Vaccinia Virus Ankara-Vaccinated Macaques with Controlled Simian-Human Immunodeficiency Virus SHIV-89.6P Challenges." *J. Virol.* **76**(20): 10147-10154.

<http://jvi.asm.org/cgi/content/abstract/76/20/10147>

In a recent vaccine trial, we showed efficient control of a virulent simian-human immunodeficiency virus SHIV-89.6P challenge by priming with a Gag-Pol-Env-expressing DNA and boosting with a Gag-Pol-Env-expressing recombinant-modified vaccinia virus Ankara. Here we show that long-term control has been associated with slowly declining levels of viral RNA and DNA. In the vaccinated animals both viral DNA and RNA underwent an initial rapid decay, which was followed by a lower decay rate. Between 12 and 70 weeks postchallenge, the low decay rates have had half-lives of about 20 weeks for viral RNA in plasma and viral DNA in peripheral blood mononuclear cells and lymph nodes. In vaccinated animals the viral DNA has been mostly unintegrated and has appeared to be largely nonfunctional as evidenced by a poor ability to recover infectious virus in cocultivation assays, even after CD8 depletion. In contrast, in control

animals, which have died, viral DNA was mostly integrated and a larger proportion appeared to be functional as evidenced by the recovery of infectious virus. Thus, to date, control of the challenge infection has appeared to improve with time, with the decay rates for viral DNA being at the lower end of values reported for patients on highly active antiretroviral therapy.

Thomsen, D. R., N. L. Oien, et al. (2003). "Amino Acid Changes within Conserved Region III of the Herpes Simplex Virus and Human Cytomegalovirus DNA Polymerases Confer Resistance to 4-Oxo-Dihydroquinolines, a Novel Class of Herpesvirus Antiviral Agents." *J. Virol.* **77**(3): 1868-1876.

<http://jvi.asm.org/cgi/content/abstract/77/3/1868>

The 4-oxo-dihydroquinolines (PNU-182171 and PNU-183792) are nonnucleoside inhibitors of herpesvirus polymerases (R. J. Brideau et al., *Antiviral Res.* 54:19-28, 2002; N. L. Oien et al., *Antimicrob. Agents Chemother.* 46:724-730, 2002). In cell culture these compounds inhibit herpes simplex virus type 1 (HSV-1), HSV-2, human cytomegalovirus (HCMV), varicella-zoster virus (VZV), and human herpesvirus 8 (HHV-8) replication. HSV-1 and HSV-2 mutants resistant to these drugs were isolated and the resistance mutation was mapped to the DNA polymerase gene. Drug resistance correlated with a point mutation in conserved domain III that resulted in a V823A change in the HSV-1 or the equivalent amino acid in the HSV-2 DNA polymerase. Resistance of HCMV was also found to correlate with amino acid changes in conserved domain III (V823A+V824L). V823 is conserved in the DNA polymerases of six (HSV-1, HSV-2, HCMV, VZV, Epstein-Barr virus, and HHV-8) of the eight human herpesviruses; the HHV-6 and HHV-7 polymerases contain an alanine at this amino acid. In vitro polymerase assays demonstrated that HSV-1, HSV-2, HCMV, VZV, and HHV-8 polymerases were inhibited by PNU-183792, whereas the HHV-6 polymerase was not. Changing this amino acid from valine to alanine in the HSV-1, HCMV, and HHV-8 polymerases alters the polymerase activity so that it is less sensitive to drug inhibition. In contrast, changing the equivalent amino acid in the HHV-6 polymerase from alanine to valine alters polymerase activity so that PNU-183792 inhibits this enzyme. The HSV-1, HSV-2, and HCMV drug-resistant mutants were not altered in their susceptibilities to nucleoside analogs; in fact, some of the mutants were hypersensitive to several of the drugs. These results support a mechanism where PNU-183792 inhibits herpesviruses by interacting with a binding determinant on the viral DNA polymerase that is less important for the binding of nucleoside analogs and deoxynucleoside triphosphates.

Towner, J. S., P. E. Rollin, et al. (2004). "Rapid Diagnosis of Ebola Hemorrhagic Fever by Reverse Transcription-PCR in an Outbreak Setting and Assessment of Patient Viral Load as a Predictor of Outcome." *J. Virol.* **78**(8): 4330-4341.

<http://jvi.asm.org/cgi/content/abstract/78/8/4330>

The largest outbreak on record of Ebola hemorrhagic fever (EHF) occurred in Uganda from August 2000 to January 2001. The outbreak was centered in the Gulu district of northern Uganda, with secondary transmission to other districts. After the initial diagnosis of Sudan ebolavirus by the National Institute for Virology in Johannesburg, South Africa, a temporary diagnostic laboratory was established within the Gulu district at St. Mary's Lacor Hospital. The laboratory used antigen capture and reverse transcription-PCR (RT-PCR) to diagnose Sudan ebolavirus infection in suspect patients. The RT-PCR and antigen-capture diagnostic assays proved very effective for detecting ebolavirus in patient serum, plasma, and whole blood. In samples collected very early in the course of infection, the RT-PCR assay could detect ebolavirus 24 to 48 h prior to detection by antigen capture. More than 1,000 blood samples were collected, with multiple samples obtained from many patients throughout the course of infection. Real-time quantitative

RT-PCR was used to determine the viral load in multiple samples from patients with fatal and nonfatal cases, and these data were correlated with the disease outcome. RNA copy levels in patients who died averaged 2 log₁₀ higher than those in patients who survived. Using clinical material from multiple EHF patients, we sequenced the variable region of the glycoprotein. This Sudan ebolavirus strain was not derived from either the earlier Boniface (1976) or Maleo (1979) strain, but it shares a common ancestor with both. Furthermore, both sequence and epidemiologic data are consistent with the outbreak having originated from a single introduction into the human population.

Traina-Dorge, V. L., R. Lorino, et al. (2005). "Molecular Epidemiology of Simian T-Cell Lymphotropic Virus Type 1 in Wild and Captive Sooty Mangabeys." *J. Virol.* **79**(4): 2541-2548.

<http://jvi.asm.org/cgi/content/abstract/79/4/2541>

A study was conducted to evaluate the prevalence and diversity of simian T-cell lymphotropic virus (STLV) isolates within the long-established Tulane National Primate Research Center (TNPRC) colony of sooty mangabeys (SMs; *Cercocebus atys*). Serological analysis determined that 22 of 39 animals (56%) were positive for STLV type 1 (STLV-1). A second group of thirteen SM bush meat samples from Sierra Leone in Africa was also included and tested only by PCR. Twenty-two of 39 captive animals (56%) and 3 of 13 bush meat samples (23%) were positive for STLV-1, as shown by testing with PCR. Nucleotide sequencing and phylogenetic analysis of viral strains obtained demonstrated that STLV-1 strains from SMs (STLV-1sm strains) from the TNPRC colony and Sierra Leone formed a single cluster together with the previously reported STLV-1sm strain from the Yerkes National Primate Research Center. These data confirm that Africa is the origin for TNPRC STLV-1sm and suggest that Sierra Leone is the origin for the SM colonies in the United States. The TNPRC STLV-1sm strains further divided into two subclusters, suggesting STLV-1sm infection of two original founder SMs at the time of their importation into the United States. STLV-1sm diversity in the TNPRC colony matches the high diversity of SIVsm in the already reported colony. The lack of correlation between the lineage of the simian immunodeficiency virus from SMs (SIVsm) and the STLV-1sm subcluster distribution of the TNPRC strains suggests that intracolony transmissions of both viruses were independent events.

Troyer, J. L., J. Pecon-Slaterry, et al. (2004). "Patterns of Feline Immunodeficiency Virus Multiple Infection and Genome Divergence in a Free-Ranging Population of African Lions." *J. Virol.* **78**(7): 3777-3791.

<http://jvi.asm.org/cgi/content/abstract/78/7/3777>

Feline immunodeficiency virus (FIV) is a lentivirus that causes AIDS-like immunodeficiency disease in domestic cats. Free-ranging lions, *Panthera leo*, carry a chronic species-specific strain of FIV, FIV-Ple, which so far has not been convincingly connected with immune pathology or mortality. FIV-Ple, harboring the three distinct strains A, B, and C defined by pol gene sequence divergences, is endemic in the large outbred population of lions in the Serengeti ecosystem in Tanzania. Here we describe the pattern of variation in the three FIV genes gag, pol-RT, and pol-RNase among lions within 13 prides to assess the occurrence of FIV infection and coinfection. Genome diversity within and among FIV-Ple strains is shown to be large, with strain divergence for each gene approaching genetic distances observed for FIV between different species of cats. Multiple infections with two or three strains were found in 43% of the FIV-positive individuals based on pol-RT sequence analysis, which may suggest that antiviral immunity or interference evoked by one strain is not consistently protective against infection by a second. This comprehensive study of FIV-Ple in a free-ranging population of lions reveals a dynamic transmission of virus in a social species that has historically adapted to render the virus benign.

Tsai, C.-T., J.-W. Ting, et al. (2005). "Complete Genome Sequence of the Grouper Iridovirus and Comparison of Genomic Organization with Those of Other Iridoviruses." J. Virol. **79**(4): 2010-2023.

<http://jvi.asm.org/cgi/content/abstract/79/4/2010>

The complete DNA sequence of grouper iridovirus (GIV) was determined using a whole-genome shotgun approach on virion DNA. The circular form genome was 139,793 bp in length with a 49% G+C content. It contained 120 predicted open reading frames (ORFs) with coding capacities ranging from 62 to 1,268 amino acids. A total of 21% (25 of 120) of GIV ORFs are conserved in the other five sequenced iridovirus genomes, including DNA replication, transcription, nucleotide metabolism, protein modification, viral structure, and virus-host interaction genes. The whole-genome nucleotide pairwise comparison showed that GIV virus was partially colinear with counterparts of previously sequenced ranaviruses (ATV and TFV). Besides, sequence analysis revealed that GIV possesses several unique features which are different from those of other complete sequenced iridovirus genomes: (i) GIV is the first ranavirus-like virus which has been sequenced completely and which infects fish other than amphibians, (ii) GIV is the only vertebrate iridovirus without CpG sequence methylation and lacking DNA methyltransferase, (iii) GIV contains a purine nucleoside phosphorylase gene which is not found in other iridoviruses or in any other viruses, (iv) GIV contains 17 sets of repeat sequence, with basic unit sizes ranging from 9 to 63 bp, dispersed throughout the whole genome. These distinctive features of GIV further extend our understanding of molecular events taking place between ranavirus and its hosts and the iridovirus evolution.

Waris, G., J. Turkson, et al. (2005). "Hepatitis C Virus (HCV) Constitutively Activates STAT-3 via Oxidative Stress: Role of STAT-3 in HCV Replication." J. Virol. **79**(3): 1569-1580.

<http://jvi.asm.org/cgi/content/abstract/79/3/1569>

The hepatitis C virus (HCV) causes chronic hepatitis, which often results in liver cirrhosis and hepatocellular carcinoma. We have previously shown that HCV nonstructural proteins induce activation of STAT-3 via oxidative stress and Ca²⁺ signaling (G. Gong, G. Waris, R. Tanveer, and A. Siddiqui, Proc. Natl. Acad. Sci. USA 98:9599-9604, 2001). In this study, we focus on the signaling pathway leading to STAT-3 activation in response to oxidative stress induced by HCV translation and replication activities. Here, we demonstrate the constitutive activation of STAT-3 in HCV replicon-expressing cells. The HCV-induced STAT-3 activation was inhibited in the presence of antioxidant (pyrrolidine dithiocarbamate) and Ca²⁺ chelators (BAPTA-AM and TMB-8). Previous studies have shown that maximum STAT-3 transactivation requires Ser727 phosphorylation in addition to tyrosine phosphorylation. Using a series of inhibitors and dominant negative mutants, we show that HCV-induced activation of STAT-3 is mediated by oxidative stress and influenced by the activation of cellular kinases, including p38 mitogen-activated protein kinase, JNK, JAK-2, and Src. Our results also suggest a potential role of STAT-3 in HCV RNA replication. We also observed the constitutive activation of STAT-3 in the liver biopsy of an HCV-infected patient. These studies provide an insight into the mechanisms by which HCV induces intracellular events relevant to liver pathogenesis associated with the viral infection.

Warke, R. V., K. Khaja, et al. (2003). "Dengue Virus Induces Novel Changes in Gene Expression of Human Umbilical Vein Endothelial Cells." J. Virol. **77**(21): 11822-11832.

<http://jvi.asm.org/cgi/content/abstract/77/21/11822>

Endothelial cells are permissive to dengue virus (DV) infection in vitro, although their importance as targets of DV infection in vivo remains a subject of debate. To analyze the virus-host interaction, we studied the effect of DV infection on gene expression in human umbilical vein endothelial cells (HUVECs) by using differential display reverse transcription-PCR (DD-RT-PCR), quantitative RT-PCR, and Affymetrix oligonucleotide microarrays. DD identified eight differentially expressed cDNAs, including inhibitor of apoptosis-1, 2'-5' oligoadenylate synthetase (OAS), a 2'-5' OAS-like (OASL) gene, galectin-9, myxovirus protein A (MxA), regulator of G-protein signaling, endothelial and smooth muscle cell-derived neuropilin-like protein, and phospholipid scramblase 1. Microarray analysis of 22,000 human genes confirmed these findings and identified an additional 269 genes that were induced and 126 that were repressed more than fourfold after DV infection. Broad functional responses that were activated included the stress, defense, immune, cell adhesion, wounding, inflammatory, and antiviral pathways. These changes in gene expression were seen after infection of HUVECs with either laboratory-adapted virus or with virus isolated directly from plasma of DV-infected patients. Tumor necrosis factor alpha, OASL, and MxA and h-IAP1 genes were induced within the first 8 to 12 h after infection, suggesting a direct effect of DV infection. These global analyses of DV effects on cellular gene expression identify potentially novel mechanisms involved in dengue disease manifestations such as hemostatic disturbance.

Widjaja, L., S. L. Krauss, et al. (2004). "Matrix Gene of Influenza A Viruses Isolated from Wild Aquatic Birds: Ecology and Emergence of Influenza A Viruses." *J. Virol.* **78**(16): 8771-8779.

<http://jvi.asm.org/cgi/content/abstract/78/16/8771>

Wild aquatic birds are the primary reservoir of influenza A viruses, but little is known about the viruses' gene pool in wild birds. Therefore, we investigated the ecology and emergence of influenza viruses by conducting phylogenetic analysis of 70 matrix (M) genes of influenza viruses isolated from shorebirds and gulls in the Delaware Bay region and from ducks in Alberta, Canada, during >18 years of surveillance. In our analysis, we included 61 published M genes of isolates from various hosts. We showed that M genes of Canadian duck viruses and those of shorebird and gull viruses in the Delaware Bay shared ancestors with the M genes of North American poultry viruses. We found that North American and Eurasian avian-like lineages are divided into sublineages, indicating that multiple branches of virus evolution may be maintained in wild aquatic birds. The presence of non-H13 gull viruses in the gull-like lineage and of H13 gull viruses in other avian lineages suggested that gulls' M genes do not preferentially associate with the H13 subtype or segregate into a distinct lineage. Some North American avian influenza viruses contained M genes closely related to those of Eurasian avian viruses. Therefore, there may be interregional mixing of the two clades. Reassortment of shorebird M and HA genes was evident, but there was no correlation among the HA or NA subtype, M gene sequence, and isolation time. Overall, these results support the hypothesis that influenza viruses in wild waterfowl contain distinguishable lineages of M genes.

Wilkinson, J., A. Cope, et al. (2002). "Identification of Kaposi's Sarcoma-Associated Herpesvirus (KSHV)-Specific Cytotoxic T-Lymphocyte Epitopes and Evaluation of Reconstitution of KSHV-Specific Responses in Human Immunodeficiency Virus Type 1-Infected Patients Receiving Highly Active Antiretroviral Therapy." *J. Virol.* **76**(6): 2634-2640.

<http://jvi.asm.org/cgi/content/abstract/76/6/2634>

Following the introduction of highly active antiretroviral therapy (HAART), the incidence of Kaposi's sarcoma (KS) has significantly declined in human immunodeficiency virus type 1 (HIV-1)-positive (HIV-1+) individuals and clinical remission is often observed. We hypothesize that these effects are partly due to anti-KS-associated herpesvirus (KSHV) immune restoration. Here, 15-mer overlapping peptides from proteins K12 and K8.1 were used to identify novel KSHV-specific cytotoxic T-lymphocyte epitopes. Three immunogenic peptides, two lytic and one latent, were subsequently used to monitor the anti-KSHV CD8+ T-cell responses in a cohort of 19 HIV-1+ KSHV+/- KS+/- individuals during 52 weeks of HAART. KSHV and HIV-1 loads, KSHV antibody titers, and both CD4+ and CD8+ T-lymphocyte counts were enumerated. Prior to HAART, the total number of spot-forming cells (SFC) for all three peptides correlated with both CD4+ and CD8+ T-lymphocyte counts ($P \leq 0.05$) in the KSHV-positive KS-positive cohort ($n = 11$). Following 52 weeks of HAART, significant decreases in HIV-1 and KSHV loads were associated with significant increases in CD4+ T-lymphocyte counts and number of SFC for the three KSHV-specific peptides. Although these increases were modest in comparison to the number of SFC observed with the HIV-1 gag peptide SLYNTVATL, they represented a fourfold increase from the baseline, continuing an upward trend to week 52.

Wilkinson, R. C., C. K. Murrell, et al. (2003). "Persistence and Dissemination of Simian Retrovirus Type 2 DNA in Relation to Viremia, Seroreponse, and Experimental Transmissibility in *Macaca fascicularis*." *J. Virol.* **77**(20): 10751-10759.

<http://jvi.asm.org/cgi/content/abstract/77/20/10751>

Endemic simian retrovirus (SRV) infection can cause fatal simian AIDS in *Macaca fascicularis*, but many individuals survive with few clinical signs. To further clarify the parameters of SRV pathogenesis, we investigated the persistence of viral DNA forms in relation to active viremia, antibody response, and transmissibility of infection. In *M. fascicularis* from endemically SRV-2-infected colonies, viral DNA was present in both linear and unintegrated long terminal repeat circular forms in peripheral blood mononuclear cells of all viremic and many nonviremic animals. Long-term followup of three individuals with distinct infection patterns demonstrated persistence of linear and circular forms of viral DNA in peripheral blood mononuclear cells and tissues, irrespective of viremia or antibody status, but reactivation of latent infections was not observed. The role of viral DNA in transmission and early pathogenesis of SRV-2 was investigated by inoculation of SRV-2 DNA-positive blood into groups of naive *M. fascicularis* from either a viremic or nonviremic donor and subsequent analysis of the virological and serological status of the recipients. Transmission of SRV and development of anti-SRV antibodies were only observed in recipients of blood from the viremic donor; transfer of SRV provirus and unintegrated circular DNA in blood from the nonviremic donor did not lead to infection of the recipients. These results indicate that a proportion of *M. fascicularis* are able to effectively control the replication and infectivity of SRV despite long-term persistence of viral DNA forms in infected lymphocytes.

Wu, E., L. Pache, et al. (2003). "Flexibility of the Adenovirus Fiber Is Required for Efficient Receptor Interaction." *J. Virol.* **77**(13): 7225-7235.

<http://jvi.asm.org/cgi/content/abstract/77/13/7225>

The adenovirus (Ad) fiber protein mediates Ad binding to the coxsackievirus and Ad receptor (CAR) and is thus a major determinant of viral tropism. The fiber contains three domains: an N-terminal tail that anchors the fiber to the viral capsid, a central shaft region of variable length and flexibility, and a C-terminal knob domain that binds to cell receptors. Ad type 37 (Ad37), a subgroup D virus associated with severe ocular infections, is unable to use CAR efficiently to infect host cells, despite containing a CAR binding site in its fiber knob. We hypothesized that the

relatively short, inflexible Ad37 fiber protein restricts interactions with CAR at the cell surface. To test this hypothesis, we analyzed the infectivity and binding of recombinant Ad particles containing modified Ad37 or Ad5 fiber proteins. Ad5 particles equipped with a truncated Ad5 fiber or with a chimeric fiber protein comprised of the Ad5 knob fused to the short, rigid Ad37 shaft domain had significantly reduced infectivity and attachment. In contrast, placing the Ad37 knob onto the long, flexible Ad5 shaft allowed CAR-dependent virus infection and cell attachment, demonstrating the importance of the shaft domain in receptor usage. Increasing fiber rigidity by substituting the predicted flexibility modules in the Ad5 shaft with the corresponding regions of the rigid Ad37 fiber dramatically reduced both virus infection and cell attachment. Cryoelectron microscopy (cryo-EM) single-particle analysis demonstrated the increased rigidity of this chimeric fiber. These studies demonstrate that both length and flexibility of the fiber shaft regulate CAR interaction and provide a molecular explanation for the use of alternative receptors by subgroup D Ad with ocular tropism. We present a molecular model for Ad-CAR interactions at the cell surface that explains the significance of fiber flexibility in cell attachment.

Wu, E., S. A. Trauger, et al. (2004). "Membrane Cofactor Protein Is a Receptor for Adenoviruses Associated with Epidemic Keratoconjunctivitis." J. Virol. **78**(8): 3897-3905.

<http://jvi.asm.org/cgi/content/abstract/78/8/3897>

Subgroup D adenovirus (Ad) types 8, 19, and 37 (Ad8, -19, and -37, respectively) are causative agents of epidemic keratoconjunctivitis and genital tract infections. Previous studies showed that Ad37 binds to a 50-kDa membrane glycoprotein expressed on human ocular (conjunctival) cells. To identify and characterize the role of the 50-kDa glycoprotein in Ad37 infection, we partially purified this molecule from solubilized Chang C conjunctival cell membranes by using lentil lectin chromatography and preparative sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Liquid chromatography coupled to nano-electrospray ionization-tandem mass spectrometry was subsequently used to identify four Ad37 receptor candidates: CD46, CD87, CD98, and CD147. Immunodepletion analyses demonstrated that the 50-kDa protein is identical to CD46 (also known as membrane cofactor protein). The Ad37, but not Ad5, fiber knob bound to the extracellular domain of CD46, demonstrating a direct interaction of an Ad37 capsid protein with CD46. An antibody specific for the N-terminal 19 amino acids of CD46 also blocked Ad37 infection of human cervical carcinoma and conjunctival cells, indicating a requirement for CD46 in infection. Finally, expression of a 50-kDa isoform of human CD46 in a CD46-null cell line increased cell binding by wild-type Ad37 and gene delivery by an Ad vector pseudotyped with the Ad37 fiber, but not by a vector bearing the Ad5 fiber. Together, these studies demonstrate that CD46 serves as an attachment receptor for Ad37 and shed further light on the cell entry pathway of subgroup D Ads.

Xu, Y., D. P. AuCoin, et al. (2005). "A Kaposi's Sarcoma-Associated Herpesvirus/Human Herpesvirus 8 ORF50 Deletion Mutant Is Defective for Reactivation of Latent Virus and DNA Replication." J. Virol. **79**(6): 3479-3487.

<http://jvi.asm.org/cgi/content/abstract/79/6/3479>

Kaposi's sarcoma-associated herpesvirus (also called human herpesvirus type 8 [HHV8]) latently infects a number of cell types. Reactivation of latent virus can occur by treatment with the phorbol ester tetradecanoyl phorbol acetate (TPA) or with the transfection of plasmids expressing the lytic switch activator protein K-Rta, the gene product of ORF50. K-Rta expression is sufficient for the activation of the entire lytic cycle and the transactivation of viral genes necessary for DNA replication. In addition, recent evidence has suggested that K-Rta may participate directly in the initiation of lytic DNA synthesis. We have now generated a recombinant HHV8 bacterial artificial

chromosome (BAC) with a large deletion within the ORF50 locus. This BAC, BAC36{Delta}50, failed to produce infectious virus upon treatment with TPA and was defective for DNA synthesis. Expression of K-Rta in trans in BAC36{Delta}50-containing cells was able to abolish both defects. Real-time PCR revealed that K-bZIP, ORF40/41, and K8.1 were not expressed when BAC36{Delta}50-containing cells were induced with TPA. However, the mRNA levels of ORF57 were over fivefold higher in TPA-treated BAC36{Delta}50-containing cells than those observed in similarly treated wild-type BAC-containing cells. In addition, immunohistochemical analysis showed that while the latency-associated nuclear antigen (LANA) was expressed in the mutant BAC-containing cells, ORF59 and K8.1 expression was not detected in TPA-induced BAC36{Delta}50-containing cells. These results showed that K-Rta is essential for lytic viral reactivation and transactivation of viral genes contributing to DNA replication.

Yamamoto, T., S. Litwin, et al. (2002). "Mutations of the Woodchuck Hepatitis Virus Polymerase Gene That Confer Resistance to Lamivudine and 2'-Fluoro-5-Methyl-{beta}-L-Arabinofuranosyluracil." J. Virol. **76**(3): 1213-1223.

<http://jvi.asm.org/cgi/content/abstract/76/3/1213>

Administration of either lamivudine (2'-deoxy-3'-thiacytidine) or L-FMAU (2'-fluoro-5-methyl-{beta}-L-arabinofuranosyluracil) to woodchucks chronically infected with woodchuck hepatitis virus (WHV) induces a transient decline in virus titers. However, within 6 to 12 months, virus titers begin to increase towards pretreatment levels. This is associated with the emergence of virus strains with mutations of the B and C regions of the viral DNA polymerase (T. Zhou et al., *Antimicrob. Agents Chemother.* 43:1947-1954, 1999; Y. Zhu et al., *J. Virol.* 75:311-322, 2001). The present study was carried out to determine which of the mutants that we have identified conferred resistance to lamivudine and/or to L-FMAU. When inserted into a laboratory strain of WHV, each of the mutations, or combinations of mutations, of regions B and C produced a DNA replication-competent virus and typically conferred resistance to both nucleoside analogs in cell culture. Sequencing of the polymerase active site also occasionally revealed other mutations, but these did not appear to contribute to drug resistance. Moreover, in transfected cells, most of the mutants synthesized viral DNA nearly as efficiently as wild-type WHV. Computational models suggested that persistence of several of the WHV mutants as prevalent species in the serum and, by inference, liver for up to 6 months following drug withdrawal required a replication efficiency of at least 10 to 30% of that of the wild type. However, their delayed emergence during therapy suggested replication efficiency in the presence of the drug that was still well below that of wild-type WHV in the absence of the drug.

Yao, Z. Q., A. Eisen-Vandervelde, et al. (2004). "Direct Binding of Hepatitis C Virus Core to gC1qR on CD4+ and CD8+ T Cells Leads to Impaired Activation of Lck and Akt." J. Virol. **78**(12): 6409-6419.

<http://jvi.asm.org/cgi/content/abstract/78/12/6409>

Complement plays a pivotal role in the regulation of innate and adaptive immunity. It has been shown that the binding of C1q, a natural ligand of gC1qR, on T cells inhibits their proliferation. Here, we demonstrate that direct binding of the hepatitis C virus (HCV) core to gC1qR on T cells leads to impaired Lck/Akt activation and T-cell function. The HCV core associates with the surface of T cells specifically via gC1qR, as this binding is inhibited by the addition of either anti-gC1qR antibody or soluble gC1qR. The binding affinity constant of core protein for gC1qR, as determined by BIAcore analysis, is 3.8×10^{-7} M. The specificity of the HCV core-gC1qR interaction is confirmed by reduced core binding on Molt-4 T cells treated with gC1qR-silencing small interfering RNA and enhanced core binding on GPC-16 guinea pig cells transfected with

human gC1qR. Interestingly, gC1qR is expressed at higher levels on CD8+ than on CD4+ T cells, resulting in more severe core-induced suppression of the CD8+-T-cell population. Importantly, T-cell receptor-mediated activation of the Src kinases Lck and ZAP-70 but not Fyn and the phosphorylation of Akt are impaired by the HCV core, suggesting that it inhibits the very early events of T-cell activation.

Ye, R., C. Montalto-Morrison, et al. (2004). "Genetic Analysis of Determinants for Spike Glycoprotein Assembly into Murine Coronavirus Virions: Distinct Roles for Charge-Rich and Cysteine-Rich Regions of the Endodomain." *J. Virol.* **78**(18): 9904-9917.

<http://jvi.asm.org/cgi/content/abstract/78/18/9904>

The coronavirus spike protein (S) forms the distinctive virion surface structures that are characteristic of this viral family, appearing in negatively stained electron microscopy as stems capped with spherical bulbs. These structures are essential for the initiation of infection through attachment of the virus to cellular receptors followed by fusion to host cell membranes. The S protein can also mediate the formation of syncytia in infected cells. The S protein is a type I transmembrane protein that is very large compared to other viral fusion proteins, and all except a short carboxy-terminal segment of the S molecule constitutes the ectodomain. For the prototype coronavirus mouse hepatitis virus (MHV), it has previously been established that S protein assembly into virions is specified by the carboxy-terminal segment, which comprises the transmembrane domain and the endodomain. We have genetically dissected these domains in the MHV S protein to localize the determinants of S incorporation into virions. Our results establish that assembly competence maps to the endodomain of S, which was shown to be sufficient to target a heterologous integral membrane protein for incorporation into MHV virions. In particular, mutational analysis indicated a major role for the charge-rich carboxy-terminal region of the endodomain. Additionally, we found that the adjacent cysteine-rich region of the endodomain is critical for fusion of infected cells, confirming results previously obtained with S protein expression systems.

Yi, Y., F. Shaheen, et al. (2005). "Preferential Use of CXCR4 by R5X4 Human Immunodeficiency Virus Type 1 Isolates for Infection of Primary Lymphocytes." *J. Virol.* **79**(3): 1480-1486.

<http://jvi.asm.org/cgi/content/abstract/79/3/1480>

Coreceptor specificity of human immunodeficiency virus type 1 (HIV-1) strains is generally defined in vitro in cell lines expressing CCR5 or CXCR4, but lymphocytes and macrophages are the principal targets in vivo. CCR5-using (R5) variants dominate early in infection, but strains that use CXCR4 emerge later in a substantial minority of subjects. Many or most CXCR4-using variants can use both CXCR4 and CCR5 (R5X4), but the pathways that are actually used to cause infection in primary cells and in vivo are unknown. We examined several R5X4 prototype and primary isolates and found that they all were largely or completely restricted to CXCR4-mediated entry in primary lymphocytes, even though lymphocytes are permissive for CCR5-mediated entry by R5 strains. In contrast, in primary macrophages R5X4 isolates used both CCR5 and CXCR4. The R5X4 strains were also more sensitive than R5 strains to CCR5 blocking, suggesting that interactions between the R5X4 strains and CCR5 are less efficient. These results indicate that coreceptor phenotyping in transformed cells does not necessarily predict utilization in primary cells, that variability exists among HIV-1 isolates in the ability to use CCR5 expressed on lymphocytes, and that many or most strains characterized as R5X4 are functionally X4 in primary lymphocytes. Less efficient interactions between R5X4 strains and CCR5 may be responsible for the inability to use CCR5 on lymphocytes, which express relatively low CCR5 levels. Since isolates that acquire CXCR4 utilization retain the capacity to use CCR5

on macrophages despite their inability to use it on lymphocytes, these results also raise the possibility that a CCR5-mediated macrophage reservoir is required for sustained infection in vivo.

Zhang, P. F., P. Bouma, et al. (2002). "A Variable Region 3 (V3) Mutation Determines a Global Neutralization Phenotype and CD4-Independent Infectivity of a Human Immunodeficiency Virus Type 1 Envelope Associated with a Broadly Cross-Reactive, Primary Virus-Neutralizing Antibody Response." *J. Virol.* **76**(2): 644-655.

<http://jvi.asm.org/cgi/content/abstract/76/2/644>

The human serum human immunodeficiency virus type 1 (HIV-1)-neutralizing serum 2 (HNS2) neutralizes many primary isolates of different clades of HIV-1, and virus expressing envelope from the same donor, clone R2, is neutralized cross-reactively by HIV-immune human sera. The basis for this cross-reactivity was investigated. It was found that a rare mutation in the proximal limb of variable region 3 (V3), 313-4 PM, caused virus pseudotyped with the R2 envelope to be highly sensitive to neutralization by monoclonal antibodies (MAbs) directed against conformation-sensitive epitopes at the tip of the V3 loop, such as 19b, and moderately sensitive to MAbs against CD4 binding site (CD4bs) and CD4-induced (CD4i) epitopes, soluble CD4 (sCD4), and HNS2. In addition, introduction of this sequence by mutagenesis caused enhanced sensitivity to neutralization by 19b, anti-CD4i MAb, and HNS2 in three other primary HIV-1 envelopes and by anti-CD4bs MAb and sCD4 in one of the three. The 313-4 PM sequence also conferred increased infectivity for CD4+ CCR5+ cells and the ability to infect CCR5+ cells upon all of these four and two of these four HIV-1 envelopes, respectively. Neutralization of R2 by HNS2 was substantially inhibited by the cyclized R2 V3 35-mer synthetic peptide. Similarly, the peptide also had some lesser efficacy in blocking neutralization of R2 by other sera or of neutralization of other primary viruses by HNS2. Together, these results indicate that the unusual V3 mutation in the R2 clone accounts for its uncommon neutralization sensitivity phenotype and its capacity to mediate CD4-independent infection, both of which could relate to immunogenicity and the neutralizing activity of HNS2. This is also the first primary HIV-1 isolate envelope glycoprotein found to be competent for CD4-independent infection.

Zhu, M., J. A. Bristol, et al. (2005). "Linked Tumor-Selective Virus Replication and Transgene Expression from E3-Containing Oncolytic Adenoviruses." *J. Virol.* **79**(9): 5455-5465.

<http://jvi.asm.org/cgi/content/abstract/79/9/5455>

Historically, the adenoviral E3 region was found to be nonessential for viral replication in vitro. In addition, adenoviruses whose genome was more than approximately 105% the size of the native genome were inefficiently packaged. These profound observations were used experimentally to insert transgenes into the adenoviral backbone. More recently, however, the reintroduction of the E3 region into oncolytic adenoviruses has been found to positively influence antitumor efficacy in preclinical models and clinical trials. In the studies reported here, the granulocyte-macrophage colony-stimulating factor (GM-CSF) cDNA sequence has been substituted for the E3-gp19 gene in oncolytic adenoviruses that otherwise retained the E3 region. Five viruses that differed slightly in the method of transgene insertion were generated and compared to Ar6pAE2fGmF (E2F/GM/{Delta}E3), a previously described E3-deleted oncolytic adenovirus encoding GM-CSF. In all of the viruses, the human E2F-1 promoter regulated E1A expression and GM-CSF expression was under the control of the adenoviral E3 promoter and the packaging signal was relocated immediately upstream from the right terminal repeat. The E3-gp19-deleted viruses had similar cytolytic properties, as measured in vitro by cytotoxicity assays, but differed markedly in their capacity to express and secrete GM-CSF. Ar15pAE2fGmF (E2F/GM/E3b), the virus that produced the highest levels of GM-CSF and retained the native GM-CSF leader sequence, was

selected for further analysis. The E2F/GM/E3b and E2F/GM/{Delta}E3 viruses exhibited similar cytotoxic activity and GM-CSF production in several tumor cell lines in vitro. However, when compared in vivo in nude mouse xenograft tumor models, E2F/GM/E3b spread through tumors to a greater extent, resulted in higher peak GM-CSF and total exposure levels in both tumor and serum, and was more efficacious than the E3-deleted virus. Using the matched WI-38 (parental) and WI-38-VA13 (simian virus 40 large T antigen transformed) cell pair, GM-CSF was shown to be selectively produced in cells expressing high levels of E2F, indicating that the tumor-selective E2F promoter controlled E1A and GM-CSF expression.

J. Wildl. Dis. (6)

Divina, B. P., E. Wilhelmsson, et al. (2002). "Molecular identification and prevalence of *Dictyocaulus* spp. (Trichostrongyloidea: Dictyocaulidae) in Swedish semi-domestic and free-living cervids." J. Wildl. Dis. **38**(4): 769-775.

<http://www.jwildlifedis.org/cgi/content/abstract/38/4/769>

Lungs of 102 roe deer (*Capreolus capreolus*), 136 moose (*Alces alces*), 68 fallow deer (*Dama dama*), and six red deer (*Cervus elaphus*) were examined during hunting seasons from 16 September 1997 to 1 March 2000. The aim was to determine the species composition and prevalence of *Dictyocaulus* lungworms in these hosts in Sweden. Worms were identified following polymerase chain reaction (PCR) amplification of the internal transcribed spacer of ribosomal DNA (ITS2), followed by hybridization with four species-specific oligonucleotides. In addition, 50 lungworms from five reindeer (*Rangifer tarandus*) from Norway were similarly analyzed. A total of 399 worms were recovered and analyzed representing a range of 29-128 worms per host species. All specimens from roe deer were identified as *Dictyocaulus capreolus*, whereas those from red deer and reindeer were identical with *D. eckerti*. From moose, 73 (81.1%) of the worms were identified as *D. capreolus* whereas 17 (18.9%) were *D. eckerti*. The ITS2 sequence of fallow deer lungworms differed significantly when compared with the ITS2 of *D. viviparus*, *D. capreolus*, and *D. eckerti*. This indicated that fallow deer in Sweden may be infected with a new genotype of *Dictyocaulus* spp. Consequently, a specific probe designed for the ITS2 from this *Dictyocaulus* sp. hybridized exclusively with samples from lungworms of fallow deer. Interestingly, no *D. viviparus* were found in any of these hosts. The prevalence of infection in each host was as follows: *D. capreolus* in roe deer (14.7%) and moose (10.6%); *D. eckerti* in moose (0.7%) and red deer (33.3%); and *Dictyocaulus* sp. in fallow deer (10.3%). Regardless of lungworm species, the overall prevalence of *Dictyocaulus* spp. in these hosts was 12.2%. Prevalence between male and female animals and among the different age groups did not differ significantly. Finally an enzyme linked immunosorbent assay (ELISA) specific for patent *D. viviparus* infection in cattle was utilized to analyze lung tissue fluids from infected animals. All samples from roe deer, red deer, and fallow deer were negative in the ELISA. However, three out of twelve (25%) samples from moose and 17 of 40 (43%) samples from cattle were positive. This indicated that moose anti-*D. capreolus* antibodies recognized the *D. viviparus* antigen and that anti-cattle immunoglobulin cross-reacted with moose antibodies.

Ketz-Riley, C. J., M. V. Reichard, et al. (2003). "An intraerythrocytic small piroplasm in wild-caught Pallas's cats (*Otocolobus manul*) from Mongolia." J. Wildl. Dis. **39**(2): 424-430.

<http://www.jwildlifedis.org/cgi/content/abstract/39/2/424>

During the quarantine examination of four Pallas's cats (*Otocolobus manul*) imported from Mongolia in October and December 2000, intraerythrocytic piroplasms were detected on Wright-Giemsa stained blood films that were morphologically indistinguishable from other small piroplasms of felids. Further characterization of this unknown organism via polymerase chain reaction amplification, sequencing of a portion of the 18S nuclear small subunit rRNA gene, and comparisons with orthologous sequences from other piroplasms, revealed similarity to *Cytauxzoon felis*. This is the first report of naturally occurring erythroparasitemia in Pallas's cats and the first documented case of naturally occurring piroplasm infections in a free-ranging felid from Mongolia.

Olsen, S. C., J. Rhyan, et al. (2004). "SAFETY OF BRUCELLA ABORTUS STRAIN RB51 IN BLACK BEARS." *J. Wildl. Dis.* **40**(3): 429-433.

<http://www.jwildlifedis.org/cgi/content/abstract/40/3/429>

In two studies conducted from October 1999 to March 2000 and December 2000 to April 2001, adult black bears (*Ursus americanus*) were orally inoculated with 1.4-3.1x10¹⁰ colony-forming units (CFU) of *Brucella abortus* strain RB51 (SRB51, n=12) or 2 ml of 0.15 M NaCl solution (saline, n=11). We did not detect a difference ($P>0.05$) in antibody titers to SRB51 in serum obtained before vaccination, at 8 wk after vaccination, or at necropsy at 21 or 23 wk after vaccination between SRB51-vaccinated and nonvaccinated bears. The SRB51 vaccine strain was recovered from tissues obtained at necropsy from one of six SRB51-vaccinated bears in study 1, but none of the six SRB51-vaccinated bears in study 2. Vaccination of black bears with SRB51 did not appear to influence ($P>0.05$) reproductive performance.

Rotstein, D. S., T. R. Schoeb, et al. (2002). "Detection by microsatellite analysis of early embryonic mortality in an alligator population in Florida." *J. Wildl. Dis.* **38**(1): 160-165.

<http://www.jwildlifedis.org/cgi/content/abstract/38/1/160>

In the 1980s, alligators (*Alligator mississippiensis*) of Lake Apopka (Florida, USA) underwent a population decline associated with decreased egg viability, effects that have been associated with endocrine-disrupting, persistent organochlorine pesticides. It is currently unknown whether the decreased egg viability is due to fertilization failure or early embryonic death. Therefore, we conducted a preliminary study to evaluate the use of microsatellite DNA loci to determine the fertilization status of nonviable eggs. Using microsatellite analysis, we compared genotypes from blasto-disks and embryos with the genotypes from females trapped at the nest. Four of five nonviable egg samples tested yielded evidence of fertilization. No evidence of unfertilized eggs was obtained, but amplifiable DNA could not be obtained from one entirely nonviable clutch. Thus, we demonstrate that early embryonic mortality in alligators can be detected by microsatellite analysis, but also suggest substantial effort is needed to improve the recovery of DNA and amplification of alligator microsatellite loci.

Schettler, E., J. Fickel, et al. (2003). "Newcastle disease virus and *Chlamydia psittaci* in free-living raptors from eastern Germany." *J. Wildl. Dis.* **39**(1): 57-63.

<http://www.jwildlifedis.org/cgi/content/abstract/39/1/57>

Organ samples from free-living raptors from the federal states of Berlin and Brandenburg in eastern Germany were tested for Newcastle disease virus (NDV; n = 331) and *Chlamydia psittaci* (n = 39) by polymerase chain reaction (PCR). In 18 individuals NDV nucleic acids were detected. These samples originated from barn owls (*Tyto alba*; n = 15, 28%), tawny owl (*Strix aluco*; n = 1, 5%), common buzzard (*Buteo buteo*, n = 1, 1%), and European kestrel (*Falco tinnunculus*; n = 1, 4%). In 29 (74%) of 39 samples *C. psittaci* was detected. *Chlamydia psittaci* is common in free-living birds of prey in the investigated area.

Stabel, J. R., M. V. Palmer, et al. (2003). "Immune responses after oral inoculation of weanling bison or beef calves with a bison or cattle isolate of *Mycobacterium avium* subsp. *paratuberculosis*." J. Wildl. Dis. **39**(3): 545-555.

<http://www.jwildlifedis.org/cgi/content/abstract/39/3/545>

Paratuberculosis is endemic in domestic and wild ruminants worldwide. We designed the following study to compare host immune responses and pathologic changes in beef calves and bison calves after challenge with either a cattle or bison (*Bison bison*) strain of *Mycobacterium avium* subsp. *paratuberculosis*. In the first part of the study, six bison and six beef calves were orally inoculated with a cattle isolate of *M. avium* subsp. *paratuberculosis* over a 2 wk period. In the second part, an additional six bison and six beef calves were similarly inoculated with a bison strain of *M. avium* subsp. *paratuberculosis*. Throughout each of the studies, blood and fecal samples were taken monthly for a 6 mo infection period. Tissue samples were obtained at necropsy for culture and histopathologic analyses. Results from this study demonstrated that bison calves were more susceptible to tissue colonization than beef calves after challenge with the cattle isolate and, conversely, that beef calves were more susceptible to the bison strain of *M. avium* subsp. *paratuberculosis*. Although lesions were minimal they were most apparent in the jejunum and distal ileum. Interferon-gamma (IFN-gamma) responses were noted in some calves by 1 mo postinoculation and were sustained longer in beef calves after challenge with the bison isolate. Antibody was not detected in either beef or bison calves during the 6 mo infection period. These results indicate that the host response to strains of *M. avium* subsp. *paratuberculosis* may differ between ruminant species.

JAMA (2)

Kim, J.-H., S. J. Skates, et al. (2002). "Osteopontin as a Potential Diagnostic Biomarker for Ovarian Cancer." JAMA **287**(13): 1671-1679.

<http://jama.ama-assn.org/cgi/content/abstract/287/13/1671>

Context Development of new biomarkers for ovarian cancer is needed for early detection and disease monitoring. Analyses involving complementary DNA (cDNA) microarray data can be used to identify up-regulated genes in cancer cells, whose products may then be further validated as potential biomarkers. Objective To describe validation studies of an up-regulated gene known as osteopontin, previously identified using a cDNA microarray system. Design, Setting, and Participants Experimental and cross-sectional studies were conducted involving ovarian cancer and healthy human ovarian surface epithelial cell lines and cultures, archival paraffin-embedded ovarian tissue collected between June 1992 and June 2001, and fresh tissue and preoperative

plasma from 144 patients evaluated for a pelvic mass between June 1992 and June 2001 in gynecologic oncology services at 2 US academic institutions. Plasma samples from 107 women selected from an epidemiologic study of ovarian cancer initiated between May 1992 and March 1997 were used as healthy controls. Main Outcome Measures Relative messenger RNA expression in cancer cells and fresh ovarian tissue, measured by real-time polymerase chain reaction as $2^{-\Delta\Delta CT}$ (a quantitative value representing the amount of osteopontin expression); osteopontin production, localized and scored in ovarian healthy and tumor tissue with immunohistochemical studies; and amount of osteopontin in patient vs control plasma, measured using an enzyme-linked immunoassay. Results The geometric mean for $2^{-\Delta\Delta CT}$ for osteopontin expression in 5 healthy ovarian epithelial cell cultures was 4.1 compared with 270.4 in 14 ovarian cancer cell lines ($P = .03$). The geometric mean $2^{-\Delta\Delta CT}$ for osteopontin expression in tissue from 2 healthy ovarian epithelial samples was 9.0 compared with 164.0 in 27 microdissected ovarian tumor tissue samples ($P = .06$). Immunolocalization of osteopontin showed that tissue samples from 61 patients with invasive ovarian cancer and 29 patients with borderline ovarian tumors expressed higher levels of osteopontin than tissue samples from 6 patients with benign tumors and samples of healthy ovarian epithelium from 3 patients ($P = .03$). Osteopontin levels in plasma were significantly higher ($P < .001$) in 51 patients with epithelial ovarian cancer (486.5 ng/mL) compared with those of 107 healthy controls (147.1 ng/mL), 46 patients with benign ovarian disease (254.4 ng/mL), and 47 patients with other gynecologic cancers (260.9 ng/mL). Conclusions Our findings provide evidence for an association between levels of a biomarker, osteopontin, and ovarian cancer and suggest that future research assessing its clinical usefulness would be worthwhile.

Kulasingam, S. L., J. P. Hughes, et al. (2002). "Evaluation of Human Papillomavirus Testing in Primary Screening for Cervical Abnormalities: Comparison of Sensitivity, Specificity, and Frequency of Referral." *JAMA* 288(14): 1749-1757.

<http://jama.ama-assn.org/cgi/content/abstract/288/14/1749>

Context Human papillomavirus (HPV) DNA testing of women having Papanicolaou (Pap) smears showing atypical squamous cells of undetermined significance (ASCUS) has clinical usefulness. Whether HPV DNA testing alone is useful in primary screening remains to be determined. Objective To determine the accuracy of HPV DNA testing for detecting cervical intraepithelial neoplasia (CIN) grade 3 or cancer (the criterion standard). Design, Setting, and Participants Between December 1997 and October 2000, 4075 women who attended Planned Parenthood clinics in Washington State were screened simultaneously using thin-layer Pap and HPV DNA testing by a polymerase chain reaction (PCR)-based method and by a liquid-based RNA-DNA hybridization capture with signal amplification assay (signal amplification). Women who were positive for high-risk HPV types, or had Pap results of ASCUS or higher, were considered to have positive screening test results and were referred for colposcopy and biopsy. Additionally, a random sample of women with negative screening test results was referred for colposcopy. Based on individual and combined thin-layer Pap, HPV PCR, and HPV signal amplification test results from the screening and the colposcopy visits, 7 colposcopy triage strategies were defined and evaluated. Main Outcome Measure Sensitivity and specificity for detecting cervical lesions graded CIN 3 or higher for each of the 7 triage strategies. Results The estimated prevalence of CIN 3 or higher was 3.2%. The sensitivity (95% confidence interval) of thin-layer Pap (with a result of $\geq$ ASCUS) for identifying women with CIN 3 or higher was only 61.3% (48.5%-70.9%) compared with 88.2% (78.9%-93.8%) for HPV testing by PCR and 90.8% (83.1%-95.8%) by signal amplification. Differences in specificities were also observed: 82.4% (81.8%-83.1%) for thin-layer Pap (with a result of $\geq$ ASCUS), 78.8% (77.9%-79.7%) for PCR, and 72.6% (69.4%-75.0%) for signal amplification. Compared with referral for colposcopy of all women with ASCUS or higher, signal amplification testing of women with ASCUS and referral of those with a positive result was about as sensitive (61.3% vs 60.3%, respectively) and significantly more specific (82.4% vs 88.9%, respectively). The strategy requiring repeat positive PCR tests on 2

visits had a sensitivity of 84.2% (75.3%-91.0%) and a specificity of 86.2% (85.1%-87.3%). All tests were more specific and less sensitive in older (≥ 30 years) vs younger women. Conclusions Testing for HPV has higher sensitivity but lower specificity than thin-layer Pap screening. In some settings, particularly where screening intervals are long or haphazard, screening for HPV DNA may be a reasonable alternative to cytology-based screening of reproductive-age women.

Japanese Journal of Ophthalmology (1)

Saitoh-Ishibashi, K., K. Ishibashi, et al. (2003). "Analysis of Cytokine mRNAs in Murine Herpes Simplex Virus Type 1 Retinitis." Japanese Journal of Ophthalmology **47**(2): 166.

<http://www.sciencedirect.com/science/article/B6VJ7-48H218P-8/2/7516af1e1363e818e1aa3558586847bb>

Purpose: To investigate cytokine mRNA expression during the inflammatory process induced in the contralateral eyes by unocular inoculation of herpes simplex virus type 1 (HSV-1) via the anterior chamber. **Methods:** BALB/c mice were inoculated in the anterior chamber with 5×10^4 plaque-forming units of HSV-1 (KOS). mRNA was extracted from the inflamed posterior segments of the uninoculated eyes at 0 (control), 9, 11, 14, and 21 days postinoculation (p.i.). Reverse transcription-polymerase chain reaction was performed for semiquantitative analysis of mRNA expression of interleukin (IL)-1[beta], IL-2, IL-4, IL-10, IL-12p35, IL-12p40, interferon (IFN)[gamma], tumor necrosis factor (TNF)[alpha], transforming growth factor (TGF)[beta]2 and induced nitric oxide synthase (iNOS). **Results:** Peak mRNA expression of iNOS was observed at day 14 p.i. The time profiles of mRNA expression for IL-1[beta], IL-2, IL-4, IL-10, IFN-[gamma], TNF[alpha] were similar to that of iNOS, while TGF[beta]2, IL-12p35, and IL-12p40 demonstrated a reverse pattern. **Conclusions:** The kinetics of the analyzed cytokines synchronized with the clinicopathological activity of the experimental murine HSV-1 retinitis. The immunosuppressive cytokines TGF[beta]2 and IL-10 demonstrated different peaks of mRNA expressions suggesting that the down-regulation phase of the inflammatory process was controlled by several factors working at different phases.

Journal of Affective Disorders (2)

Levitan, R. D., M. Masellis, et al. (2002). "Polymorphism of the serotonin-2A receptor gene (HTR2A) associated with childhood attention deficit hyperactivity disorder (ADHD) in adult women with seasonal affective disorder." Journal of Affective Disorders **71**(1-3): 229.

<http://www.sciencedirect.com/science/article/B6T2X-46G3SNW-11/2/2c42dea4e95eec1494615917938b6122>

Introduction: Several lines of research point to a possible overlap between seasonal affective disorder (SAD) and attention deficit hyperactivity disorder (ADHD), particularly in females. There

is also emerging evidence that variation of the 5-HT_{2A} receptor gene (HTR2A) contributes to both SAD and ADHD. The current study investigated whether variation in HTR2A was associated with symptoms of childhood ADHD in adult women with SAD. Method: Sixty-six women with SAD were administered the Wender-Utah Rating Scale (WURS), which retrospectively assesses childhood ADHD, as part of an ongoing genetic study of SAD. WURS scores were compared across the three genotypic groups defined by the T102C polymorphism of HT2RA. Results: Analysis of variance indicated a significant difference in mean 25-item WURS scores across the three genotypic groups ($p=0.035$). Post-hoc tests revealed that the C/C genotypic group had a significantly higher mean score than both the T/T group and T/C group. Based on previously established WURS criteria, 38% of subjects with the C/C genotype, and none with the T/T genotype, had scores consistent with childhood ADHD. Limitations: The current sample size is small, and childhood ADHD diagnoses were based on retrospective recall. Conclusion: These preliminary results suggest a possible association between variation in HTR2A, childhood ADHD, and the later development of SAD in women.

Mitchell, P., B. Waters, et al. (1993). "Exclusion of close linkage of bipolar disorder to the dopamine D3 receptor gene in nine Australian pedigrees." *Journal of Affective Disorders* **27**(4): 213.

<http://www.sciencedirect.com/science/article/B6T2X-46040F6-D2/2/f75179efda6dc9a007d69b47606532cf>

The recently cloned dopamine D3 receptor (DRD3) gene is of potential relevance to the aetiology of bipolar disorder because of an almost exclusive expression in limbic tissue, the region of the brain putatively responsible for control of emotion. We therefore aimed to determine whether bipolar disorder in nine pedigrees (with 171 members) was linked to this receptor gene, which has been mapped to chromosomal region 3q 13.3. Linkage of bipolar disorder and recurrent depression to the DRD3 gene was tested using a series of autosomal dominant and recessive models with varying penetrance levels. Additionally, linkage was examined using a series of levels of definitions of affective illness (ranging from bipolar I alone to all affective disorders). Close linkage to the DRD3 gene was strongly excluded using each model and definition, and these conclusions persisted when a wide range of rates of 'sporadic' (non-genetic) presentations of illness were incorporated in the analysis.

Journal of Allergy and Clinical Immunology (7)

Jogie-Brahim, S., H.-K. Min, et al. (2004). "Expression of [alpha]-tryptase and [beta]-tryptase by human basophils." *Journal of Allergy and Clinical Immunology* **113**(6): 1086.

<http://www.sciencedirect.com/science/article/B6WH4-4CMHF7S-1G/2/b4e803c222ee16aeee4b4e40dd51fd35>

Background[alpha] and [beta]-Tryptase levels in serum are clinical tools for the evaluation of systemic anaphylaxis and systemic mastocytosis. Basophils and mast cells are known to produce these proteins.
ObjectiveThe current study examines the effect of the [alpha],[beta]-tryptase genotype on basophil tryptase levels and the type of tryptase stored in these cells.
MethodsTryptase extracted from purified peripheral blood basophils from 20 subjects was examined by using ELISAs measuring mature and total tryptase and by using an enzymatic

assay with tosyl-Gly-Pro-Lys-p-nitroanilide. Tryptase genotypes (4:0, 3:1, and 2:2 [beta]/[alpha] ratios) were assessed by using a hot-stop PCR technique with [alpha],[beta]-tryptase-specific primers. Total [alpha],[beta]-tryptase mRNA was measured by means of competitive RT-PCR, and ratios of [alpha] to [beta]-tryptase mRNA were measured by means of hot-stop RT-PCR. Results Tryptase in all but one of the basophil preparations was mature and enzymatically active. Tryptase quantities in basophils were less than 1% of those in tissue mast cells. Tryptase genotypes ([beta]/[alpha]) among the 20 donors were 4:0 in 7, 3:1 in 7, and 2:2 in 6. Tryptase protein and mRNA levels per basophil were not affected by the tryptase genotype. Conclusion Basophils from healthy subjects contain modest amounts of mature and enzymatically active tryptase unaffected by the tryptase genotype.

Min, H.-K., G. Moxley, et al. (2004). "Effect of sex and haplotype on plasma tryptase levels in healthy adults." Journal of Allergy and Clinical Immunology **114**(1): 48.

<http://www.sciencedirect.com/science/article/B6WH4-4CS46C4-19/2/6287b60b49ecc666c1442e4fba184209>

Background The total level of [alpha]-tryptase and [ss]-tryptase in serum or plasma is used as a clinical indicator of the mast cell burden. Objective The effect of the tryptase haplotype and of sex on the total tryptase level of healthy individuals was determined. Methods A novel hot-stop PCR technique was used to determine the tryptase genotype, and a standard fluoroenzyme immunoassay was used to measure total plasma tryptase levels in 106 healthy subjects. Mx modeling and the QTL association routine of Mendel 5.0 were used to analyze the data. Results Tryptase haplotypes exhibit a 1 ([ss][alpha]/[ss][alpha]):2 ([ss][ss]/[ss][alpha]):1 ([ss][ss]/[ss][ss]) distribution, monomorphic for [ss] at 1 position and allelic for [ss] and [alpha] at the other position. The [ss][alpha] haplotype has a frequency of 0.49. The [ss][alpha] haplotype increases total tryptase levels by 0.5 ng/mL from the overall mean, whereas female sex increases the level by 0.2 ng/mL from the mean. Conclusion The tryptase haplotype and sex each have a statistically significant effect on the total plasma tryptase level of healthy subjects.

1S/2/bb20ef226e632a3e772d1bb264dff411

Background Atopic dermatitis (AD) is a chronic inflammatory skin disease involving colonization by superantigen (SAg)-secreting *Staphylococcus aureus*. CD4+CD25+ T regulatory (Treg) cells are thought to play an important role in controlling inflammatory responses. **Objective** In this study we examined whether Treg cells might be deficient in patients with AD. **Methods** CD4+CD25+ and CD4+CD25- T cells were isolated from PBMCs by using immunomagnetic beads. Cells were cultured with anti-CD3 or SAg, staphylococcal enterotoxin B (SEB), for 72 hours. Proliferation was measured by means of tritiated thymidine incorporation. CD4, CD8, CD25, and cutaneous lymphocyte-associated antigen expression on PBMCs was assessed by means of flow cytometry. RNA was extracted from isolated subsets of T cells, and the results of real-time PCR for FoxP3 mRNA were determined. **Results** Surprisingly, CD4+CD25+ T cells were significantly ($P < 0.05$) in skin-homing, CD4+, cutaneous lymphocyte-associated antigen-positive T cells than asthmatic and nonatopic subjects, with values of 35.95% versus 22.44% versus 23.03%, respectively ($P < 0.05$). CD4+CD25+ cells expressed FoxP3, whereas CD4+CD25- T cells and CD4- cells did not. Consistent with known properties of Treg cells, CD4+CD25+ cells were anergic to anti-CD3 stimulation. When CD4+CD25+ cells from each study group were mixed with CD4+CD25- cells, proliferative responses were equally suppressed after anti-CD3 stimulation. In contrast, after SEB stimulation, CD4+CD25+ cells were no longer anergic. Furthermore, when CD4+CD25+ cells were mixed with CD4+CD25- cells and stimulated with SEB, the suppressive function of Treg cells was reversed. **Conclusion** Patients with AD have significantly increased numbers of peripheral blood Treg cells with normal immunosuppressive activity. However, after SAg stimulation, Treg cells lose their immunosuppressive activity. These data suggest a novel mechanism by which SAg could augment T-cell activation in patients with AD.

Roy, S. R., A. M. Schiltz, et al. (2003). "Bacterial DNA in house and farm barn dust." *Journal of Allergy and Clinical Immunology* **112**(3): 571.

<http://www.sciencedirect.com/science/article/B6WH4-49W6061-1B/2/aed95e490b7cf57540a02596335ac880>

Background Early in life, natural exposure to microbial components (eg, endotoxin) may mitigate allergy and asthma development in childhood. Bacterial DNA is a potent stimulus for the innate immune system; its immune stimulatory potential in dust is unknown. **Objectives** We sought to quantify bacterial DNA and endotoxin content in dust from urban homes, rural homes, farm homes, and farm barns and to determine if dust DNA is immune-stimulatory. **Methods** Total DNA, bacterial DNA, and endotoxin were measured in 32 dust samples. To measure bacterial DNA content, a quantitative polymerase chain reaction assay specific for bacterial ribosomal DNA was developed. Peripheral blood mononuclear cells from 5 adults were stimulated with endotoxin-free dust DNA with/without lipopolysaccharide (LPS) from selected dust samples. IL-12p40, IL-10, and tumor necrosis factor- α were measured in cell supernatants by enzyme-linked immunosorbent assay. **Results** Bacterial DNA in dust correlated with endotoxin ($r = 0.56$, $P = 0.003$). The highest bacterial DNA levels were measured in farm barns (mean, 22.1 $\mu\text{g/g}$ dust; range, 1.3 to 56.2), followed by rural homes (6.3 $\mu\text{g/g}$; 0.2 to 20), farm homes (2.2 $\mu\text{g/g}$; 0.1 to 9.1), and urban homes (0.6 $\mu\text{g/g}$; 0.1 to 1.2). Farm barn DNA significantly potentiated ($P < 0.05$) endotoxin-induced IL-12p40 and IL-10 production. **Conclusions** Endotoxin is a marker for bacterial DNA, which is also higher in locales of lower asthma and allergy prevalence. DNA from farm barn dust augments the immune modulatory effects of endotoxin and may combine with exposure to other such naturally occurring microbial components to mitigate allergy and asthma development.

Srivastava, K., A. A. Teper, et al. (2004). "Immunomodulatory effect of the antiasthma Chinese herbal formula MSSM-002 on TH2 cells." *Journal of Allergy and Clinical Immunology* **113**(2): 268.

<http://www.sciencedirect.com/science/article/B6WH4-4BMC07G-1C/2/c3d030c51782d264d6d825b47c3fe86c>

Background TH2 cytokines play a central role in the pathogenesis of allergic asthma. We previously showed that the "antiasthma" Chinese herbal formula MSSM-002 exhibited therapeutic effects on established allergic airway responses in a murine model of allergic asthma. However, the mechanisms underlying these effects are largely unknown. **Objective** The objective of this study was to determine whether and how MSSM-002 modulates an established TH2 response and whether the actions of MSSM-002 on TH2 cell differs from corticosteroids. **Methods** TH2 polarized splenocytes (TH2-SPCs) from mice with antigen-induced airway hyperresponsiveness and TH2 cloned cells, D10 G4.1 (D10), were cultured in the presence or absence of antigen with or without MSSM-002 and dexamethasone, and the proliferative responses and cytokine profiles were determined. Apoptosis and TH2 transcription factor GATA-3 expression and binding to IL-4 gene promoter and VA enhancer in MSSM-002-treated D10 cells were also determined. **Results** MSSM-002 significantly decreased antigen-induced proliferation and IL-4 and IL-5 production but increased IFN- γ production by TH2-SPCs, whereas dexamethasone suppressed IFN- γ as well as IL-4 and IL-5. Anti-IL-12 antibody, although abrogating MSSM-002 induction of IFN- γ , had no significant effect on MSSM-002 suppression of IL-4 and IL-5 secretion. MSSM-002 also suppressed TH2 cytokine secretion by D10 cells, and in contrast to dexamethasone, MSSM-002 did not induce apoptosis of D10 cells. MSSM-002 markedly suppressed GATA-3 mRNA and protein expression and the binding to IL-4 gene promoter and VA enhancer in D10 cells. **Conclusion** MSSM-002, in contrast to the overall suppression of T cells by dexamethasone, exhibits immunomodulatory actions on TH2 cells caused, at least partially, by downregulation of GATA-3.

Journal of Autoimmunity (4)

Ide, A., E. Kawasaki, et al. (2004). "Association between IL-18 gene promoter polymorphisms and CTLA-4 gene 49A/G polymorphism in Japanese patients with type 1 diabetes." Journal of Autoimmunity **22**(1): 73.

<http://www.sciencedirect.com/science/article/B6WHC-4B22WHV-1/2/7d78cada8c5b7fa05f7c932b7ccc2270>

Interleukin-18 (IL-18) is a potent proinflammatory cytokine which is strongly associated with the development of diabetes in NOD mice. To test the putative involvement of IL-18 gene polymorphism in predisposition to human type 1 diabetes, the SNPs at position -607 (C/A) and -137 (G/C) in the promoter region of IL-18 gene were analyzed by sequence-specific PCR in 116 patients with type 1 diabetes and 114 normal controls. A linkage disequilibrium found only three of the four possible haplotypes defined by these SNPs. The distribution of the IL-18 gene genotypes at position -607 was significantly different between patients with type 1 diabetes and normal controls ($P=0.023$). Furthermore, there was a significant increase in haplotype 1 (-607C/-137G) in the patients compared with controls ($P=0.006$). The association study of the susceptible CTLA-4 genotype (GG at nucleotide position 49 in exon 1) or HLA-DR4-DQB1*0401 and type 1 diabetes showed that the predisposing IL-18 gene haplotype modulates the risk on CTLA-4 GG genotype, but not on HLA-DR4-DQB1*0401 haplotype. Among subjects carrying the CTLA-4 GG genotype, the frequency of IL-18 haplotype 1 in patients with type 1 diabetes was significantly higher than that in controls (91% vs. 71%, $P=0.012$). However, IL-18 haplotype 1 was not frequent in patients who do not exhibit the CTLA-4 high-risk genotype. These results suggest that the IL-18 gene polymorphism is associated with a type 1 diabetes susceptibility, and there might

be a gene-gene interaction between IL-18 gene with susceptible CTLA-4 gene.

Neumann, E., S. Lechner, et al. (2003). "Evaluation of differentially expressed genes by a combination of cDNA array and RAP-PCR using the AtlasImage(TM) 2.0 software." Journal of Autoimmunity **21**(2): 161.

<http://www.sciencedirect.com/science/article/B6WHC-494HM8F-1/2/69e6bdb8a3967fbd3ab540909ecccc04>

Evaluation of genes regulated differentially is essential for the development of therapeutic approaches in multifactorial diseases. To characterize gene expression profiles in multifactorial inflammatory and malignant diseases such as rheumatoid arthritis (RA) or colon adenoma (CA), RNA arbitrarily primed PCR (RAP-PCR) combined with cDNA array hybridization were performed and evaluated using an array-specific software. RNA of synovial fibroblasts from patients with RA and osteoarthritis (OA), and laser microdissected normal and colon adenoma tissue was used. RAP-PCR reactions were hybridized to cDNA array membranes. Arrays were analyzed by phosphor imaging, and the AtlasImage(TM) 2.0 software with different normalization settings. The AtlasImage(TM) 2.0 software was a useful tool to evaluate differentially expressed genes. However, software settings were needed to be optimized for every experimental approach and should be used without changes for all experiments. To compare RA vs. OA synovial fibroblasts and normal vs. CA expression patterns, global normalization using the sum method is recommended.

Wapenaar, M. C., M. J. van Belzen, et al. (2004). "The interferon gamma gene in celiac disease: augmented expression correlates with tissue damage but no evidence for genetic susceptibility." Journal of Autoimmunity **23**(2): 183.

<http://www.sciencedirect.com/science/article/B6WHC-4CWBJRN-2/2/21172f2666ae69962a7442d7a58395a8>

Celiac disease (CD) is a complex genetic disorder characterized by gluten intolerance. The Th1 immune response, with a key position for interferon gamma (IFN-[gamma]), is an important determinant of intestinal remodeling in CD. We aimed at further ascertaining the role of IFN-[gamma], either as a genetic factor in the etiology, or as a facilitator of disease initiation/progression. Duodenal biopsies were sampled across distinct histopathological stages of the disease, including refractory CD (RCD), and used to determine IFN-[gamma] gene (IFNG) expression by real-time RT-PCR. INFG expression correlated with the extent of tissue restructuring, reaching a 240-fold higher expression in total villous atrophy compared to healthy tissue. CD and RCD patients with similar lesions had comparable expression levels. Interestingly, patients in complete remission still had 7.6-fold residual over-expression. An INFG marker was tested in three cohorts of Dutch patients for both genetic linkage and association. Linkage analysis yielded no significant scores for IFNG or its flanking markers. In addition, IFNG allele frequencies were not differently distributed between cases and controls. Likewise, all alleles were randomly transmitted to affected children in parents-case trios. There is no evidence for IFNG as a predisposing gene in CD, despite its enhanced expression in patients in complete remission.

Zhang, J., C. Vandevyver, et al. (1995). "Activation and clonal expansion of human Myelin Basic Protein-reactive T cells by bacterial superantigens." Journal of Autoimmunity **8**(4): 615.

<http://www.sciencedirect.com/science/article/B6WHC-4DB57WR-D/2/7caf4be3e45267f0477464ad143bd923>

Autoreactive T cells specific for myelin basic protein (MBP) are part of the normal T cell repertoire and are present both in patients with multiple sclerosis (MS) and healthy individuals. There is evidence suggesting in vivo activation and persistent clonal expansion of MBP-reactive T cells in MS. This study was undertaken to investigate the potential role of bacterial superantigens (SA) in the activation of MBP-reactive T cells. Twenty-seven MBP-reactive T cell clones generated from 10 MS patients and one normal individual were examined for reactivity to SA, in association with their T cell receptor V[beta] gene usage. The majority of the clones responded to at least one of the SA tested, staphylococcal enterotoxins (SEA and SEB) and toxic shock syndrome toxin-1 (TSST-1). The clones reactive to SEA and SEB expressed various V[beta] genes while T cell reactivity to TSST-1 correlated with the V[beta]2 expression. Furthermore, circulating MBPreactive T cells could be expanded from lymphocyte cultures primarily exposed to respective SA in more than 50% of MS patients and normal individuals tested. However, activation and expansion of circulating MBPreactive T cells by SA was not directly associated with the disease. This study lends support to the potential role of SA in the activation of MBP-reactive T cells and suggests that an altered regulatory mechanism may account for further expansion and persistence of MBP-reactive T cells in MS.

Journal of Biochemical and Biophysical Methods (14)

Burkhart, C. A., M. D. Norris, et al. (2002). "A simple method for the isolation of genomic DNA from mouse tail free of real-time PCR inhibitors." Journal of Biochemical and Biophysical Methods **52**(2): 145.

<http://www.sciencedirect.com/science/article/B6T28-46HJMPJ-2/2/d8f639256a9e5983ff8fceed0137e308>

Although real-time PCR is a rapid, quantitative method for the analysis of gene and RNA levels, the presence of inhibitors in samples is an obstacle to its successful use. We have found that genomic DNA isolated from mouse tail tips using a standard proteinase K digestion method caused marked inhibition of real-time PCR. Inhibition was specific for mouse tail DNA since genomic DNA isolated from other tissue sources using the same methodology was readily amplified. We have therefore developed a nonproteinase K DNA isolation method involving the use of Chelex(R) 100 resin. This method produces mouse tail DNA that is free of real-time PCR inhibitors.

Falzon, L., C. Kirk, et al. (1994). "PCR generation of large amounts of purified DNA." Journal of Biochemical and Biophysical Methods **29**(3-4): 251.

<http://www.sciencedirect.com/science/article/B6T28-47NVM5J-6/2/cd2c380957833a38c4147fcddac6673e>

The preparation and purification of PCR generated DNA fragments suitable for footprinting and classical drug binding studies is described. One of the fragments, a 214-mer derived from pBR322 DNA exhibits a biphasic melting profile. This behavior appears to be due to a non-

random distribution of base pairs within the fragment causing a region rich in AT base pairs to melt prior to a segment having a high concentration of GC base pairs. The usefulness of large amounts of PCR generated DNA for footprinting and optical binding studies involving drugs is also presented and discussed.

Giordano, M., M. Mellai, et al. (2001). "Determination of SNP allele frequencies in pooled DNAs by primer extension genotyping and denaturing high-performance liquid chromatography." Journal of Biochemical and Biophysical Methods **47**(1-2): 101.

<http://www.sciencedirect.com/science/article/B6T28-429Y53Y-C/2/6fe14bea71f71b178da1b9f60cc4b7df>

By testing DNA pools rather than single samples the number of tests for a case-control association study can be decreased to only two for each marker: one on the patient and one on the control pool. A fundamental requirement is that each pool represents the frequency of the markers in the corresponding population beyond the influence of experimental errors. Consequently the latter must be carefully determined. To this aim, we prepared pools of different size (49-402 individuals) with accurately quantified DNAs, estimated the allelic frequencies in the pools of two SNPs by primer extension genotyping followed by DHPLC analysis and compared them with the real frequencies determined in the single samples. Our data show that (1) the method is highly reproducible: the standard deviation of repeated determinations was ± 0.014 ; (2) the experimental error (i.e., the discrepancy between the estimated and real frequencies) was ± 0.013 (95% C.I.: 0.0098-0.0165). The magnitude of this error was not correlated to the pool size or to the type of SNP. The effect of the observed experimental error on the power of the association test was evaluated. We conclude that this method constitutes an efficient tool for high-throughput association screenings provided that the experimental error is low. We therefore recommend that before a pool is used for extensive association studies, its quality, i.e., the experimental error, is verified by determining the difference between estimated and real frequencies for at least one marker.

Gullicksen, P. S., R. G. Dean, et al. (2004). "Detection of DNA fragmentation and apoptotic proteins, and quantification of uncoupling protein expression by real-time RT-PCR in adipose tissue." Journal of Biochemical and Biophysical Methods **58**(1): 1.

<http://www.sciencedirect.com/science/article/B6T28-49JHR0K-4/2/cb03d8f49eb3270582a36a35c7fde837>

Better understanding of the mechanisms involved in adipose tissue growth and metabolism is critical for the development of more effective treatments for obesity. However, because of its high lipid and low protein content, adipose tissue can present unique problems in some experimental procedures. We describe three protocols that provide new or improved methods for analysis of DNA, RNA, and protein from different adipose tissues. The first protocol provides a simple and rapid method for separation of fragmented DNA and visualization of apoptotic DNA laddering without the need for radioisotopes. This technique allows for an estimate of the amount of DNA fragmentation, and hence, apoptosis. The second protocol details subcellular fractionation of adipose tissue for the extraction of protein in the mitochondrial and cytosol fractions and the measurement of apoptotic protein (Bcl-2 and Bax) levels in each fraction. The last protocol involves extraction of total RNA from adipose tissue and the measurement of uncoupling protein mRNA using real-time RT-PCR, a method that has not previously been used to measure expression of uncoupling proteins in adipose tissue.

Huber, C. G., A. Premstaller, et al. (2001). "Mutation detection by capillary denaturing high-performance liquid chromatography using monolithic columns." Journal of Biochemical and Biophysical Methods **47**(1-2): 5.

<http://www.sciencedirect.com/science/article/B6T28-429Y53Y-2/2/8b095b042b00341d566dae95d00f5604>

The high resolving power of the chromatographic separation of single- and double-stranded nucleic acids in 200 [μm] i.d. monolithic poly(styrene-divinylbenzene) capillary columns was utilized for mutation screening in polymerase chain reaction amplified polymorphic loci. Recognition of mutations is based on the separation of homo- and heteroduplex species by ion-pair reversed-phase high-performance liquid chromatography (IP-RP-HPLC) under partially denaturing conditions, resulting in characteristic peak patterns both for homozygous and heterozygous samples. Six different single nucleotide substitutions and combinations thereof were confidently identified in 413 bp amplicons from six heterozygous individuals each of which yielded a different unique chromatographic profile. Alternatively, mutations were identified in short, 62 bp PCR products upon their complete on-line denaturation at 75[deg]C taking advantage of the ability of IP-RP-HPLC to resolve single-stranded nucleic acids of identical length that differ in a single nucleotide. Separations in monolithic capillary columns can be readily hyphenated to electrospray ionization mass spectrometry and promise increased sample throughput by operating in arrays similar to those already used in capillary electrophoresis.

Katsahambas, S. and M. T. W. Hearn (1996). "Application of an optimised reverse transcriptase-polymerase chain reaction method to determine the cDNA nucleotide sequence of porcine basic fibroblast growth factor." Journal of Biochemical and Biophysical Methods **33**(3): 231.

<http://www.sciencedirect.com/science/article/B6T28-3Y2FV5D-8/2/ee6a7e7dcb66b95b444a76937936a61d>

In the present investigation, oligonucleotide primers of high hybridisation stringency have been used in combination with optimised reverse transcriptase-polymerase chain reaction (RT-PCR) methods for the determination of the cDNA sequence corresponding to porcine FGF-2 mRNA present in brain and uterine tissue. Application of these optimised methods have overcome previous limitations associated with the low abundance of the porcine FGF-2 mRNA, and allowed as little as 100 [μg] of tissue to be employed to generate the complete cDNA nucleotide sequences as well as to provide specific template fragments selected for their suitability in subsequent ligation and mutagenesis studies with conventional expression vectors. Comparisons of the cDNA nucleotide and the deduced amino-acid sequence of porcine FGF-2 and the known FGF-2s from other species have indicated nucleotide sequence homologies of 95.5% with the bovine, 94.7% with the human and 88.7% with the rat FGF-2 cDNA whilst amino-acid sequence homologies of 100% with the bovine, 98.7% with the human and 96.8% with the rat FGF-2, respectively, were found. Based on these investigations, application of analogous strategies and methods with low abundance mRNAs related to other members of this family of growth factors, as well as very low abundance mRNAs of other protein growth factor, in the pig should now be readily realised.

Kosaki, K., H. Yoshihashi, et al. (2001). "Fluorescence-based DHPLC for allelic quantification by single-nucleotide primer extension." Journal of Biochemical and Biophysical Methods **47**(1-2): 111.

<http://www.sciencedirect.com/science/article/B6T28-429Y53Y-D/2/bdeb926e5ac4cb9aa646cd408b5ba262>

We have investigated the possibility of determining quantitatively the alleles of binary DNA polymorphisms by single-nucleotide primer extension (SNUPE) and fluorescence-based DHPLC. Using a polymorphism of interest to our group, ROX-labeled dideoxy CTP (ROX-ddCTP) was incorporated at the 3' end of the primer annealed to the template adjacent to the polymorphic site. The primer extension product was then resolved from the unincorporated dye terminator by ion-pair reversed-phase liquid chromatography. The signal intensity of incorporated ROX-ddCTP correlated well over one order of magnitude with the relative amount of the C-allele present in the genomic DNA template. We conclude that SNUPE, when combined with fluorescence-based DHPLC, can accurately determine the relative molar proportion of one allele in total DNA.

Lombardi, M. P., M. J. B. van den Hoff, et al. (2003). "Expression analysis of subtractively enriched libraries (EASEL): a widely applicable approach to the identification of differentially expressed genes." Journal of Biochemical and Biophysical Methods **57**(1): 17.

<http://www.sciencedirect.com/science/article/B6T28-48JK5S4-2/2/dc5e5536d80fb6c6e9d899399170b7e5>

A variety of methods for high throughput analysis of differential gene expression has been developed over the past years. We have implemented the EASEL technique that adds flexibility, efficiency and wide-applicability to these methods. The EASEL procedure is unique as it integrates several well established techniques and thereby offers a combination of subtractive hybridization of 3' cDNA ends with macroarrays analysis and Serial Analysis of Gene Expression (SAGE). In addition, once a set of interesting, differentially expressed genes is identified, the material required for follow up studies to test the hypothesis that the gene is truly involved in the process of interest is readily available. In this report, we first present a step-by-step validation of the procedure, since several of the incorporated steps had to be tailored to meet specific requirements and implied drastic modifications of the original methods. Secondly, we applied EASEL to the identification of up-regulated gene products in the outflow tract region of the embryonic rat heart. Here we provide evidence that at least two among the differentially expressed genes detected, follistatin-like protein gene and membrane type 1-metallo proteinase gene, are selectively up-regulated in the outflow tract, suggesting their involvement in the development of this region during embryogenesis.

Nath, K., J. W. Sarosy, et al. (2000). "Effects of ethidium bromide and SYBR(R) Green I on different polymerase chain reaction systems." Journal of Biochemical and Biophysical Methods **42**(1-2): 15.

<http://www.sciencedirect.com/science/article/B6T28-3Y15WC0-2/2/f503da156ac52de77a9f31e22913133e>

In an in-gel polymerase chain reaction (PCR), the generation of a 1750-bp yeast DNA fragment was inhibited when yeast DNA gel-stabs or gel-slices stained with ethidium bromide (EtBr) or SYBR(R) Green I were used. Similar inhibition occurred to a varying degree in the reamplification of PCR fragments in prokaryotic systems. Inclusion of the dyes in PCR resulted in an inhibition at about 10 [mu]g/ml EtBr and at 10,000-20,000-fold dilution of SYBR(R) Green I in all systems. The effect remained unchanged despite increasing the PCR cycles to 40. However, increasing the magnesium chloride concentration did reverse the inhibitory actions, although the PCR specificity was lost. In an unusual observation, we find that, at higher dye concentrations (50 [mu]g/ml EtBr,

or thousand fold dilution of SYBR(R) Green I), the input yeast DNA electrophoretic profile is maintained following 25 PCR cycles (despite a denaturation temperature of 94[deg]C). It varied significantly in different DNA systems and was readily reversed by high Mg++ concentrations. It is concluded that, at low Mg++ concentrations, different PCR systems are inhibited to varying extents by intercalating dyes and, in some PCR systems, intercalating dyes at unusually high concentrations maintain input DNA electrophoretic profile.

Nordstrom, T., A. Alderborn, et al. (2002). "Method for one-step preparation of double-stranded DNA template applicable for use with Pyrosequencing(TM) technology." Journal of Biochemical and Biophysical Methods **52**(2): 71.

<http://www.sciencedirect.com/science/article/B6T28-46HJMPJ-1/2/a26d61dd3fd4580c69894558dfd3f6a6>

A new one-step method for fast and efficient preparation of double-stranded DNA template, suitable for use with Pyrosequencing(TM) technology, has been developed. In the new method, two different types of oligonucleotides were used to prevent reannealing of remaining PCR primers to the template: oligonucleotides complementary to the PCR primers and 3'-end modified oligonucleotides with the same sequence as the PCR primers. Advantages with the new strategy are: (i) faster and simpler template preparation procedure (one-step); (ii) no need for exonuclease I treatment; and (iii) less problem with unspecific priming from loop structures and dimers. By careful oligonucleotide design, and/or by addition of single-stranded DNA-binding protein, problems with unspecific sequence signals due to mispriming can be reduced. The new method was used for analysis of genotype variations within the renin-angiotensin-aldosterone system.

Roberts, P. S., S. Jozwiak, et al. (2001). "Denaturing high-performance liquid chromatography (DHPLC) is a highly sensitive, semi-automated method for identifying mutations in the TSC1 gene." Journal of Biochemical and Biophysical Methods **47**(1-2): 33.

<http://www.sciencedirect.com/science/article/B6T28-429Y53Y-4/2/94f0c3b5a800e14a5b834f4c502b0815>

Sensitive and automated methods for the detection of DNA sequence variation are required for a wide variety of genetic studies. Diagnostic testing in human genetic disorders is one application of such methods. Tuberous sclerosis complex (TSC) is an autosomal dominant familial tumor syndrome characterized by the development of benign tumors (hamartomas) in multiple organs (OMIM # 19110, #191092). There is a high frequency of sporadic cases and significant demand from patients and families for genetic testing information. Two TSC genes have been identified (TSC1 and TSC2) and together account for all cases [1 and 2]. Here we report our methods for DHPLC analysis of the TSC1 gene and demonstrate the high sensitivity of this method in a blinded analysis of 21 TSC patients with known TSC1 mutations. In this series, DHPLC detected 27/28 (96%) known TSC1 sequence variations. The only sequence variation not identified by DHPLC in this study is a mosaic case.

Seth, D., M. D. Gorrell, et al. (2003). "SMART amplification maintains representation of relative gene expression: quantitative validation by real time PCR and application to studies of alcoholic liver disease in primates." Journal of Biochemical and Biophysical Methods **55**(1): 53.

<http://www.sciencedirect.com/science/article/B6T28-47MSRBD->

1/2/e903600f32d9314a752839b8ea02cad7

The small quantities of tissue available for most studies of human disease are a significant limitation for meaningful gene expression profiling. The Atlas Switch Mechanism At the 5' end of Reverse Transcript (SMART(TM)) probe amplification kit uses as little as 50 ng of total RNA to generate complex cDNA probes for DNA array and other analyses. However, the extent to which this attractive methodology maintains representation of relative gene expression has not been quantified. In this study, we demonstrate using real-time quantitative PCR analysis that the relative expression levels of a range of low- to high-abundance mRNAs are retained after SMART amplification independent of transcript abundance and full-length transcript, coding region and PCR product size. Using this technology, a mean amplification of 3800-fold was achieved in human liver samples, greatly enhancing the ability to perform replicate DNA array experiments. Probes generated with the SMART amplification method were used to detect increased expression of genes involved with inflammation, fibrosis, xenobiotic metabolism, immune function, oxidant stress and endothelium in liver from the baboon model of alcoholic liver disease.

Suzuki, T., M. Akimoto, et al. (2005). "A new PCR-based approach for the preparation of RNA probe." Journal of Biochemical and Biophysical Methods **62**(3): 251.

<http://www.sciencedirect.com/science/article/B6T28-4F473MF-1/2/12e5c2652c39908f0fa0af90410868f0>

A number of PCR-based in situ hybridization (ISH) techniques have been reported to facilitate the procedure. However, those techniques require additional gene specific primers with RNA polymerase binding site. We developed a new PCR-based ISH technique without extra gene-specific primers. We amplified gene specific PCR products with regular gene-specific primer pairs. Special linker, including T7 RNA polymerase binding site, was adapted to amplified PCR products. Secondary PCR was performed with T7 primer, and forward or reverse primer, used for the first PCR to prepare template DNA for RNA transcription. We were able to generate sense and anti-sense probes for ISH in a day. Recently, real-time PCR and ISH are required to validate microarray results quantitatively and qualitatively. This technique can be expected to facilitate the high-throughput validation of transcripts detected by microarrays.

van den Boom, D., A. Ruppert, et al. (1997). "Combined amplification and sequencing in a single reaction using two DNA polymerases with differential incorporation rates for dideoxynucleotides." Journal of Biochemical and Biophysical Methods **35**(2): 69.

<http://www.sciencedirect.com/science/article/B6T28-3RC4TD2-1/2/bb6e63c5486309c3e3e295f45a1eb451>

We describe an approach, which combines the process of DNA amplification and sequence determination by using a pair of primers and two DNA polymerases with different incorporation rates for dideoxynucleotides. The process of target sequence amplification is carried out by the DNA polymerase with a low dideoxynucleotide incorporation rate while its polymerase counterpart with a high incorporation rate generates a sequence ladder. The needs for separate amplification via polymerase chain reaction (PCR) or cloning into plasmids including the respective purification steps therefore can be avoided. In addition, the use of dye terminator chemistry enables the simultaneous generation of forward and reverse sequence ladders, which can be separated based on the streptavidin-biotin system when one amplification primer is biotinylated.

Tanaka, S. M., J. Li, et al. (2003). "Effects of broad frequency vibration on cultured osteoblasts." Journal of Biomechanics **36**(1): 73.

<http://www.sciencedirect.com/science/article/B6T82-47DGWG4-9/2/52920f4949c343217d2d48064e4b36f2>

Bone is subjected in vivo to both high amplitude, low frequency strain, incurred by locomotion, and to low amplitude, broad frequency strain. The biological effects of low amplitude, broad frequency strain are poorly understood. To evaluate the effects of low amplitude strains ranging in frequency from 0 to 50 Hz on osteoblastic function, we seeded MC3T3-E1 cells into collagen gels and applied the following loading protocols for 3 min per day for either 3 or 7 days: (1) sinusoidal strain at 3 Hz, with 0-3000 μ strain peak-to-peak followed by 0.33 s resting time, (2) "broad frequency vibration" of low amplitude strain (standard deviation of 300 μ strain) including frequency components from 0 to 50 Hz, and (3) sinusoidal strain combined with broad frequency vibration (S+V). The cells were harvested on day 4 or 8. We found that the S+V stimulation significantly repressed cell proliferation by day 8. Osteocalcin mRNA was up-regulated 2.6-fold after 7 days of S+V stimulation, and MMP-9 mRNA was elevated 1.3-fold after 3 days of vibration alone. Sinusoidal stimulation alone did not affect the cell responses. No differences due to loading were observed in alkaline phosphatase activity and in mRNA levels of type I collagen, osteopontin, connexin 43, MMPs-1A, -3, -13. These results suggest that osteoblasts are more sensitive to low amplitude, broad frequency strain, and this kind of strain could sensitize osteoblasts to high amplitude, low frequency strain. This suggestion implies a potential contribution of stochastic resonance to the mechanical sensitivity of osteoblasts.

Ahmed, K., S. Chohnan, et al. (2003). "Purification, bacteriolytic activity, and specificity of [beta]-lytic protease from *Lysobacter* sp. IB-9374." Journal of Bioscience and Bioengineering **95**(1): 27.

<http://www.sciencedirect.com/science/article/B6VSD-49GYVN6-1S/2/a1db729715796e2ced6ed23648e92595>

Lysobacter sp. IB-9374, which was isolated from soil as a high lysyl endopeptidase-producing strain (Chohnan et al., FEMS Microbiol. Lett., 213, 13-20, 2002), was found to produce a [beta]-lytic protease capable of lysing gram-positive bacteria such as *Staphylococcus aureus*, *Micrococcus eus*, and *Bacillus subtilis*. The *Lysobacter* strain secreted the [beta]-lytic protease into the culture medium at a 2.4-fold higher level than *Achromobacter lyticus*. The enzyme was highly purified through a series of six steps with a high yield. The enzyme was strongly inhibited by tetraethylene-pentamine and 1,10-phenanthroline. The purified enzyme lysed more efficiently almost all the gram-positive bacteria tested than lysozyme, lysostaphin, and mutanolysin. The enzyme was very similar to *Achromobacter* [beta]-lytic protease containing one zinc atom in terms of amino acid composition and N-terminal sequence. The nucleotide sequence revealed that the mature enzyme was composed of 179 amino acid residues with additional 198 amino

acids at the amino-terminal end of the enzyme. The deduced amino acid sequence of the mature enzyme coincided with that of the *Achromobacter* enzyme, although the prepro-region showed a 41% sequence identity with the counterpart. These results indicate that *Lysobacter* sp. is a useful strain for an efficient large-scale preparation of [beta]-lytic protease capable of lysing bacteria.

Fujii, T., H. Sugino, et al. (2002). "Characterization of the microbial community in an anaerobic ammonium-oxidizing biofilm cultured on a nonwoven biomass carrier." Journal of Bioscience and Bioengineering **94**(5): 412.

<http://www.sciencedirect.com/science/article/B6VSD-48KCSM4-7/2/3e71266ed9da71523ce58d428ed912d9>

The enrichment and characterization of anaerobic ammonium-oxidizing biofilm cultures are ongoing in our laboratories. Biomass, with a predominately red color, demonstrating simultaneous removal of ammonium and nitrite under autotrophic and anoxic conditions, which is characteristic of anaerobic ammonium-oxidizing planctomycetes, was enriched and maintained for an extended period on a polyester nonwoven carrier. To investigate the bacterial composition of the mature biofilm community, 16S rDNA sequences were amplified by PCR and comparative analyses using DNA databases were conducted. Only one sequence had a notable similarity (92.2%) to that of the first discovered anaerobic ammonium-oxidizing planctomycete and lesser, yet significant, similarities to the 16S rDNA sequences of other recently reported anaerobic ammonium-oxidizing strains. The newly discovered strain (designated KSU-1) reported here was dominant among detectable members of the biofilm community. By fluorescence imaging, KSU-1 was shown to form spherical clusters wrapped in a thin layer of *Zoogloea* sp. Possible interactions and interdependencies of these two species are discussed with regard to the putative unculturability of the anaerobic ammonium-oxidizing planctomycetes.

Kato, T., M. Haruki, et al. (2001). "Isolation and characterization of long-chain-alkane degrading *Bacillus thermoleovorans* from deep subterranean petroleum reservoirs." Journal of Bioscience and Bioengineering **91**(1): 64.

<http://www.sciencedirect.com/science/article/B6VSD-43CTKX4-D/2/929454cd3e5a3820325c2ebbae3ed357>

Two extremely thermophilic alkane-degrading bacterial strains, B23 and H41, were respectively isolated from deep subterranean petroleum reservoirs in the Minami-aga (Niigata) and Yabase (Akita) oil fields. Both strains were able to grow at temperatures ranging from 50 to 80[deg]C, with optimal growth at 70[deg]C for B23 and 65[deg]C for H41. From 16S rRNA gene sequence analysis and physiological characterization, both strains were identified as *Bacillus thermoleovorans* (identities of 99.5% and 99.6% to strain DSM 5366, and 98.3% and 98.7% to the type strain LEH-1TS, respectively). Strains B23 and H41 effectively (60%) degraded n-alkanes longer than C12 and C15, respectively, at 70[deg]C, while strain LEH-1TS degraded undecane (C11) most effectively. When B23 and H41 were cultivated in the presence of heptadecane, heptadecanoate and pentadecanoate were specifically accumulated in the cells. These results strongly suggest that the two strains degraded n-alkanes by a terminal oxidation pathway, followed by a [beta]-oxidation pathway.

Kawagoshi, Y., S. Nakamura, et al. (2004). "Isolation of aryl-phosphate ester-degrading bacterium from leachate of a sea-based waste disposal site." Journal of Bioscience and Bioengineering **98**(6):

<http://www.sciencedirect.com/science/article/B6VSD-4FB66DB-B/2/6c84c70a46d677c72124dd0522a0aa39>

An aryl-phosphate ester (APE)-degrading bacterium was isolated from the leachate of a sea-based waste disposal site. The isolated APE-degrading bacterial strain YS-57 grew well in a medium containing glucose and NaCl, and degraded two types of APE: tricresyl phosphate and triphenyl phosphate. The optimal temperature, pH, and NaCl concentration for the growth of strain YS-57 were 30[deg]C, 7.0, and 1.0%, respectively. Strain YS-57 grew at an APE concentration of 25 mg/l without being inhibited. APEs were degraded by the supernatant of the medium in which strain YS-57 was cultured, suggesting that the APE-degrading enzyme was released into the extracellular space in the logarithmic growth phase. The 16S rDNA sequence of strain YS-57 showed 95.6% similarity to that of *Roseobacter gallaeciensis* and the morphological properties were also comparable. Consequently, strain YS-57 was closely related to the genus *Roseobacter*.

Matsubara, Y., R. Kawada, et al. (2000). "Cloning and sequence analysis of a gene (aly PG) encoding poly([alpha]-guluronate) lyase from *Corynebacterium* sp. strain ALY-1." Journal of Bioscience and Bioengineering **89**(2): 199.

<http://www.sciencedirect.com/science/article/B6VSD-409W3NW-J/2/ad5d3b710b04dbf583031e77feedd0ad>

The aly PG gene, coding for a poly [alpha]-guluronate lyase (PG lyase) of *Corynebacterium* strain ALY-1, was cloned and sequenced. The gene consists of 768 bp encoding a signal peptide of 32 amino acids and a mature protein of 224 amino acids. Two disulfide bond cross-linkages were found to be formed between Cys-4 and Cys-51 and between Cys-200 and Cys-206 in the native PG lyase molecule. The deduced amino acid sequence of the *Corynebacterium* sp. aly PG gene exhibited 29% homology toward that of the *Klebsiella pneumoniae*, subsp. *aerogenes* aly A gene, with two conserved regions (the amino acid sequences from Y-102 to M-110 and from Y-221 to Q-229).

Minamida, K., I. N. Sujaya, et al. (2004). "The effects of Di--fructofuranose-1,2':2,3'-dianhydride (DFA III) administration on human intestinal microbiota." Journal of Bioscience and Bioengineering **98**(4): 244.

<http://www.sciencedirect.com/science/article/B6VSD-4DTSGN1-3/2/ccdfa0294e10555a9ff58320dfda8cd4>

Di--fructofuranose-1,2':2,3'-dianhydride (DFA III) was shown to enhance Ca absorption in rat and human intestine. The effects of DFA III administration (9 g per day for 4 weeks that corresponded to 3-fold the optimal dosage of DFA III) on human intestinal microbiota were studied using denaturing gradient gel electrophoresis (DGGE). The major groups of human intestinal microbiota reported previously: the *Bacteroides*, the *Clostridium* *coccoides* group (*Clostridium* cluster XIVa), the *Clostridium* *leptum* group (*Clostridium* cluster IV), and the *Bifidobacterium* group were detected. The similarity of 30 DGGE profiles based on the V3 region (before and after administration to the 15 subjects) of the 16S rDNA were calculated using Pearson's correlation based on numbers, positions and intensity of bands, and then a dendrogram of DGGE profiles was constructed by the unweighted pair group method using arithmetic average (UPGMA) clustering method. By these analyses, no difference in DGGE profiles after DFA III administration

was observed in healthy subjects, while two subjects with chronic constipation showed different profiles, namely on numbers, positions and the intensity of some bands. Their stools were softer and stool frequencies increased and they obtained relief from constipation.

Mori, K., M. Hatsu, et al. (2000). "Effect of heavy metals on the growth of a methanogen in pure culture and coculture with a sulfate-reducing bacterium." Journal of Bioscience and Bioengineering **90**(3): 260.

<http://www.sciencedirect.com/science/article/B6VSD-41XVBHW-6/2/1ac265263170e5445202f4e0e2271b65>

The sensitivity of a methanogen and sulfate-reducing bacterium isolated from a sea-based landfill site to Cd²⁺ and Cu²⁺ was studied. Methanogens and sulfate-reducing bacteria in leachates of the waste disposal site were enumerated using the MPN method. Methanobacterium thermoautotrophicum KHT-2, isolated from the leachate, could not grow at 0.5 mM Cd²⁺ or 1.0 mM Cu²⁺. Desulfotomaculum sp. RHT-3, isolated from the same leachate, was able to insolubilize 3.0 mM Cd²⁺ or 2.0 mM Cu²⁺ by production of hydrogen sulfide. When strains KHT-2 and RHT-3 were cultured together in the presence of the heavy metals, strain KHT-2 could grow at high heavy metal concentrations after insolubilization of the metals by strain RHT-3.

Nakano, H., K. Kobayashi, et al. (2000). "Single-step single-molecule PCR of DNA with a homo-priming sequence using a single primer and hot-startable DNA polymerase." Journal of Bioscience and Bioengineering **90**(4): 456.

<http://www.sciencedirect.com/science/article/B6VSD-426YS50-N/2/b7e99e44285b101e467aded8c40d3e66>

We have previously reported that a protein library can be constructed by directly combining PCR amplification of a single DNA molecule and cell-free protein synthesis. To specifically amplify single DNA molecules, however, two-step PCR with nested primers was used. Here we describe a simpler method for single-step amplification of a single molecule. The method involves the use of both hot-startable DNA polymerase and a DNA template that has homo-priming sequences at both ends for amplification using a single primer. These two modifications greatly decreased the possibility of formation and subsequent accumulation, respectively, of primer-dimers that inhibit the amplification of target template. In addition, a high-fidelity DNA polymerase was successfully used, resulting in the significant reduction of the accumulation of mutations during amplification.

Pedro, M. S., S. Haruta, et al. (2003). "Isolation and characterization of predominant microorganisms during decomposition of waste materials in a field-scale composter." Journal of Bioscience and Bioengineering **95**(4): 368.

<http://www.sciencedirect.com/science/article/B6VSD-49D202X-8/2/1bb08b5d0ffa9cdb9e4235d382c0a7bb>

A self-heating field-scale composter treating agro-industrial wastes within a period of 30 d was analyzed by denaturing gradient gel electrophoresis (DGGE) (Pedro et al., J. Biosci. Bioeng., 91, 159-165, 2001). Three major bands were derived from Propionibacterium acnes, Methylobacterium mesophilicum or M. radiotolerans, and Bacillus thermocloacae. Strains MSP09A and MSP06G with close affiliation to P. acnes and B. thermocloacae, respectively, were

successfully isolated. Based on quantitative-PCR results, the relative population of MSP09A increased towards the end of the composting process (mesophilic stage) while MSP06G seemed to predominate during the middle period (thermophilic stage). These results correlated highly with their growth temperatures. MSP09A and MSP06G had different metabolic profiles which were largely affected by culture conditions. MSP09A was able to utilize large complex molecules of lipids and proteins. An interspecies relationship in terms of metabolites such as propionic acid was expected between the two microorganisms.

Salvador Pedro, M., S. Haruta, et al. (2001). "Denaturing gradient gel electrophoresis analyses of microbial community from field-scale composter." Journal of Bioscience and Bioengineering **91**(2): 159.

<http://www.sciencedirect.com/science/article/B6VSD-431BBWD-9/2/25a8761c69c583fa0c0e8e515c6e065a>

The diversity of microbial community during the decomposition of waste in a field-scale composter (Hazaka system) was investigated by denaturing gradient gel electrophoresis (DGGE). The composter operates at a high temperature through a self-heating system, creating a thermophilic (60-76[deg]C) stage during the initial phase and a mesophilic (45[deg]C) stage towards the later phase of the composting period. The pH of the system (pH 7.75-8.10) did not vary significantly during the process while moisture content was reduced from 48.8% to 25.1%. DGGE and 16S rDNA analyses showed that the following genera were found throughout the process: *Propionibacterium* sp., *Methylobacterium* sp., *Pseudomonas* sp., and *Bradyrhizobium* sp. Different *Bacillus* spp. thrive at the thermophilic or the mesophilic stage while *Clostridium* sp. was only found at the initial phase of the process. *Staphylococcus* sp. and *Caulobacter* sp. or *Brevundimonas* sp. existed during the later phase of the composting period.

Sujaya, I. N., Y. Tamura, et al. (2003). "Development of internal transcribed spacer regions amplification restriction fragment length polymorphism method and its application in monitoring the population of *Zygosaccharomyces rouxii* M2 in miso fermentation." Journal of Bioscience and Bioengineering **96**(5): 438.

<http://www.sciencedirect.com/science/article/B6VSD-4BCWP93-5/2/baa6010b89632bd885fa91aadb7a62f5>

Recently, the use of the dry yeast of *Zygosaccharomyces rouxii* M2 for miso (soybean paste) fermentation has been established. A molecular monitoring method was developed and validated in this study to analyze the population of *Z. rouxii* M2 during the fermentation. The method was based on the restriction patterns of internal transcribed spacer (ITS) regions of the rDNA using *HaeIII* and *HhaI*. Among the homologous ITS regions of *Z. rouxii* strains, *Z. rouxii* M2 produced diagnostic bands by which it can be differentiated from the other strains used. The specific restriction bands were due to the difference in nucleotide sequence of two different copies of ITS of *Z. rouxii* M2. Both ITS copies showed 94% sequence similarity but a 13-bp nucleotide substitution and a 19-bp deletion were found in the ITS1 region. Phylogenetic trees were constructed based on ITS and 18S rDNA sequences and it was found that the ITS sequences provide better resolution for the classification of *Z. rouxii* M2. Since *Z. rouxii* M2 is a promising strain for use in miso fermentation as a dry starter, the method developed is significant in terms of industrial application in monitoring the growth of *Z. rouxii* M2 in miso fermentation.

Yin, Q. and Q. Zheng (2005). "Isolation and identification of the dominant *Lactobacillus* in gut and faeces of pigs using carbohydrate fermentation and 16S rDNA analysis." Journal of Bioscience and Bioengineering **99**(1): 68.

<http://www.sciencedirect.com/science/article/B6VSD-4FPN41C-C/2/bdba62d68269b852bb0901795855e6a1>

The gut contents and faeces of 9 adult pigs and 387 colonies growing on MRS culture (selective for *Lactobacillus*) were sampled to isolate and identify *Lactobacillus* species present. The results showed that the number of bacteria growing on MRS culture increased from the anterior to posterior of the gut and decreased in the faeces (e.g., stomach, 4.04×10^5 cfu/g; small intestine, 9.77×10^7 cfu/g; large intestine 3.85×10^{11} cfu/g; faeces, 1.22×10^{11} cfu/g). Fifty-two lactobacilli-like colonies were selected from 387 on the basis of their size and Gram staining, and used for the fermentation of 11 carbohydrates, from which 12 lactobacilli were selected for 16S rDNA analysis. The result showed that *Lactobacillus ruminis* was the dominant *Lactobacillus* in the stomach, small intestine, large intestine and faeces of pigs. The identification of most strains estimated by their 16S rDNA was 98-99% accurate.

Yoza, B., A. Arakaki, et al. (2003). "Fully automated DNA extraction from blood using magnetic particles modified with a hyperbranched polyamidoamine dendrimer." Journal of Bioscience and Bioengineering **95**(1): 21.

<http://www.sciencedirect.com/science/article/B6VSD-49GYVN6-1R/2/c472f5041ed10e830ce1c1e1c805ddbf>

Bacterial and artificial magnetic particles were modified using a polyamidoamine (PAMAM) dendrimer and outer shell amines determined. Bacterial magnetic particles were the most consistently modified. Transmission electron microscopic (TEM) analysis showed that the artificial magnetic particles were structurally damaged by the modification process including sonication. Furthermore, laser particle analysis of the magnetite also revealed damage. Small quantities of dendrimer-modified bacterial magnetic particles were used to extract DNA from blood. The efficiency of DNA recovery was consistently about 30 ng of DNA using 2-10 [μg] of dendrimer-modified bacterial magnetite. This technique was fully automated using newly developed liquid handling robots and bacterial magnetic particles.

Journal of Biotechnology (18)

Bangrak, P., P. Graidist, et al. (2004). "Molecular cloning and expression of a mammalian homologue of a translationally controlled tumor protein (TCTP) gene from *Penaeus monodon* shrimp." Journal of Biotechnology **108**(3): 219.

<http://www.sciencedirect.com/science/article/B6T3C-4BSVBH3-1/2/c4e9bc3a418367b798304506578fbdfa>

White spot syndrome, caused by white spot syndrome virus (WSSV), is a deadly disease of shrimps, causing a catastrophic loss in shrimp industries worldwide. In order to investigate molecular response of shrimp haemocyte to WSSV infection, we performed subtraction

hybridization of mRNAs from healthy and WSSV-infected haemocyte. One of the genes that were severely down-regulated in moribund WSSV-infected-haemocyte was translationally controlled tumor protein (TCTP) (or fortilin). Strikingly, while there was a slight difference in the amount of TCTP message between normal and early WSSV-infected shrimps, shrimps that exhibited severe symptoms uniformly had very little TCTP in their haemocyte. Taken together with the fact that TCTP functions as an anti-apoptotic protein in mammals, our data suggest that TCTP in shrimp protects WSSV-infected shrimps from death.

Barlaan, E. A., M. Sugimori, et al. (2005). "Electronic microarray analysis of 16S rDNA amplicons for bacterial detection." Journal of Biotechnology **115**(1): 11.

<http://www.sciencedirect.com/science/article/B6T3C-4DNB0SC-1/2/9b91c5ad283767c1ef860a53ee0ff38b>

Electronic microarray technology is a potential alternative in bacterial detection and identification. However, conditions for bacterial detection by electronic microarray need optimization. Using the NanoChip electronic microarray, we investigated eight marine bacterial species. Based on the 16S rDNA sequences of these species, we constructed primers, reporter probes, and species-specific capture probes. We carried out two separate analyses for longer (533 bp) and shorter (350 and 200 bp) amplified products (amplicons). To detect simultaneously the hybridization signals for the 350- and 200-bp amplicons, we designed a common reporter probe from an overlapping sequence within both fragments. We developed methods to optimize detection of hybridization signals for processing the DNA chips. A matrix analysis was performed for different bacterial species and complementary capture probes on electronic microarrays. Results showed that, when using the longer amplicon, not all bacterial targets hybridized with the complementary capture probes, which was characterized by the presence of false-positive signals. However, with the shorter amplicons, all bacterial species were correctly and completely detected using the constructed complementary capture probes.

Cox, M., G. Gerritse, et al. (2001). "Characterization of the promoter and upstream activating sequence from the *Pseudomonas alcaligenes* lipase gene." Journal of Biotechnology **86**(1): 9.

<http://www.sciencedirect.com/science/article/B6T3C-42D2C33-2/2/10035fdf5e07870efb6874c8619c7ce4>

Pseudomonas alcaligenes secretes a lipase with a high pH optimum, which has interesting properties for application in detergents. The expression of the lipase is strongly dependent on the presence of lipids in the growth medium such as soybean oil. The promoter of the gene was characterized and found to have resemblance to σ^{54} controlled promoters, which are known to be tightly regulated. The transcription start was mapped precisely downstream of a sequence with close similarity to the -12/-24 consensus sequence of σ^{54} controlled promoters. Interestingly, a hyperproducer mutant strain was isolated and found to have a C to T mutation in the -12/-24 promoter consensus region. In addition an Upstream Activating Sequence (UAS) with homology to σ^{54} UAS consensus sequences was identified. It was demonstrated that an increase of the distance from the UAS to the transcription start or the deletion of the UAS results in significantly lower expression levels of lipase. A systematic mutational analysis of the UAS sequence has resulted in a variant with an increased lipase expression.

Gerritse, G., R. Ure, et al. (1998). "The phenotype enhancement method identifies the Xcp outer membrane secretion machinery from *Pseudomonas alcaligenes* as a bottleneck for lipase production." Journal of Biotechnology **64**(1): 23.

<http://www.sciencedirect.com/science/article/B6T3C-3TXT1RT-4/2/087c52ad9fe7ed6bb35a2dc49dcad9a9>

Pseudomonas alcaligenes M-1 has been selected from an intensive screening for micro-organisms that can naturally produce a lipase active in detergent formulations. The lipase expression has been increased to allow high level secretion from *Pseudomonas alcaligenes*, via the introduction of multi-copy plasmids. In order to improve the lipase yield further, the phenotype enhancement method has been developed. This idea comprises the reintroduction of a cosmid library with random chromosomal fragments in a *P. alcaligenes* strain with already high lipase productivity. One of the strains which showed an enhanced lipase production appeared to contain a cosmid encoding the outer membrane secretion genes. These xcp-genes are clustered in two divergently transcribed operons similar to the situation in *Pseudomonas aeruginosa*. Remarkably and dissimilar to *P. aeruginosa*, in between the two xcp gene clusters, two reading frames of unknown function--OrfV and OrfX--are present. For OrfX no equivalent can be found in the known protein data bases. On the other hand, OrfV shows homology to the regulatory proteins MalT and AcoK. Some evidence is provided that suggests that OrfV acts as a regulator of the xcp operons. A model is proposed for the regulation of the secretion system from *P. alcaligenes*.

Hoshino, T., S. Tsuneda, et al. (2003). "In situ PCR for visualizing distribution of a functional gene "amoA" in a biofilm regardless of activity." Journal of Biotechnology **105**(1-2): 33.

<http://www.sciencedirect.com/science/article/B6T3C-497RD6K-5/2/ac6be9a7b587218391573b694fc36425>

In this study, ammonia-oxidizing bacteria present in biofilms resulting from a nitrifying reactor were detected by both a conventional FISH technique and an original in situ PCR technique. Both techniques showed that ammonia-oxidizing bacteria were found near the surface of the biofilms. However, after the biofilm had been exposed to 2 weeks of ammonia starvation, ammonia-oxidizing bacteria present in the biofilm could not be detected by fluorescence in situ hybridization (FISH) because they did not have sufficient copies of rRNA. In contrast, ammonia-oxidizing bacteria could be detected by in situ PCR with strong signal. It was thus demonstrated that a cell possessing a specific functional gene is detectable by in situ PCR regardless of its activity.

Lee, M.-H. and J.-W. Kwak (2003). "Expression and functional reconstitution of a recombinant antibody (Fab') specific for human apolipoprotein B-100." Journal of Biotechnology **101**(2): 189.

<http://www.sciencedirect.com/science/article/B6T3C-47P1TYB-3/2/037704017bc58504efc5473a0da9615d>

We have cloned and constructed plasmid vectors, pETB23H and pETB23L, for bacterial expression of heavy (H) and light (L) chain cDNAs of Fab' of mAbB23 a monoclonal antibody specific to human plasma apolipoprotein (apo) B-100. The H- and L-chains were expressed as insoluble inclusion bodies in the cytoplasm of *Escherichia coli*. The inclusion bodies of both chains were isolated from the cell lysate, solubilized in 6 M guanidium-HCl, and mixed in equal molar amounts. Refolding was performed in three stages of dialysis: first, dialysis against 3 M guanidium buffer, next, continuous decrement of guanidium in the dialysis buffer through slow addition of 1 M guanidium buffer, and finally, dialysis against a buffer without guanidium. After the

refolding, active Fab' (rFab') was purified through an apo B-100-coupled affinity column. When compared by ELISA, the rFab' had a slightly decreased antigen-binding activity (about 0.7-fold) compared with native Fab. The refolding yield was maximum (75%) when performed at the protein concentrations not more than 0.4 mg ml⁻¹, whereas the yield decreased exponentially at higher concentrations. The maximum recovery was obtained at the refolding concentration of 1.8 mg ml⁻¹, where the yield was about 45%. Overall, 2.4-3.0 mg of active rFab' specific to apo B-100 was successfully obtained from 1 l cultivation of E. coli cells.

Murakami, Y., K. Motohashi, et al. (1994). "Micromachined electroporation system for transgenic fish." Journal of Biotechnology **34**(1): 35.

<http://www.sciencedirect.com/science/article/B6T3C-47DKVN8-69/2/faf17e0f000e06bad7a6fb02f1634aab>

Luciferase gene was introduced into fertilized eggs of medaka by a localized electric field between thin film electrodes formed on a glass plate. Miniaturization of the electrodes enabled us to apply a localized electric field to the animal pole of the fertilized egg. Biochemical luminescence and an electrophoresis pattern showed expression and integration of the gene, respectively. The presented system had a higher ratio of gene introduction than the conventional electroporation method.

Nakagawa, T., T. Tanaka, et al. (2005). "Fabrication of amino silane-coated microchip for DNA extraction from whole blood." Journal of Biotechnology **116**(2): 105.

<http://www.sciencedirect.com/science/article/B6T3C-4DXBSVF-4/2/6e9182282cb57ba1937b65701215f8c6>

A simple microchip device for DNA extraction was constructed based on electrostatic interactions between surface amine groups and DNA. Microchannel was fabricated on silicon wafer by photolithography and coated with 3-aminopropyltriethoxysilane (APTES) or 3-[2-(2-aminoethylamino)-ethylamino]-propyltrimethoxysilane (AEEA) to introduce amine groups on the surface. Determination of the number of surface amine groups and optimization of DNA capture condition were demonstrated to characterize the microchip. Capacities of capturing DNA were approximately 97 ng/cm² in APTES and 194 ng/cm² in AEEA modified microchips, respectively. The amount of DNA captured in the microchip increased depending on surface amine density. Furthermore, DNA extraction using amine-coated microchip from whole blood was examined. Quantification of DNA and proteins in washing or eluting fraction indicates that proteins were removed at washing steps and only DNA was effectively eluted by changing alkalinity of buffer from pH 7.5 to 10.6. The amount of DNA extracted from whole blood was approximately 10 ng and its recovery ratio was 27-40%. Performance of PCR for the eluted fraction indicates that DNA extracted from whole blood was well purified using amine-coated microchip.

Neves-Petersen, M. T., E. I. Petersen, et al. (2001). "Engineering the pH-optimum of a triglyceride lipase: from predictions based on electrostatic computations to experimental results." Journal of Biotechnology **87**(3): 225.

<http://www.sciencedirect.com/science/article/B6T3C-42WP5JM-4/2/c4cc8a2fe818bc975a9bafa0dd287c4c>

The optimisation of enzymes for particular purposes or conditions remains an important target in virtually all protein engineering endeavours. Here, we present a successful strategy for altering the pH-optimum of the triglyceride lipase cutinase from *Fusarium solani* pisi. The computed electrostatic pH-dependent potentials in the active site environment are correlated with the experimentally observed enzymatic activities. At pH-optimum a distinct negative potential is present in all the lipases and esterases that we studied so far. This has prompted us to propose the 'The Electrostatic Catapult Model' as a model for product release after cleavage of the ester bond. The origin of the negative potential is associated with the titration status of specific residues in the vicinity of the active site cleft. In the case of cutinase, the role of Glu44 was systematically investigated by mutations into Ala and Lys. Also, the neighbouring Thr45 was mutated into Proline, with the aim of shifting the spatial location of Glu44. All the charge mutants displayed altered titration behaviour of active site electrostatic potentials. Typically, the substitution of the residue Glu44 pushes the onset of the active site negative potential towards more alkaline conditions. We, therefore, predicted more alkaline pH optima, and this was indeed the experimentally observed. Finally, it was found that the pH-dependent computed Coulombic energy displayed a strong correlation with the observed melting temperatures of native cutinase.

Nielsen, P. S., H. Ohlsson, et al. (2005). "Expression profiling by oligonucleotide microarrays spotted on coated polymer slides." *Journal of Biotechnology* **116**(2): 125.

<http://www.sciencedirect.com/science/article/B6T3C-4F0181B-1/2/9a0d5bb3b3b1e37686628b1fac5932af>

We have developed a ready-to-spot polymer microarray slide, which is coated with a uniform layer of reactive electrophilic groups using anthraquinone-mediated photo-coupling chemistry. The slide coating reduces the hydrophobicity of the native polymer significantly, thereby enabling robust and efficient one-step coupling of spotted 5' amino-linked oligonucleotides onto the polymer slide. The utility of the coated polymer slide in gene expression profiling was assessed by fabrication of spotted oligonucleotide microarrays using a collection of 5' amino-linked 70-mer oligonucleotide probes representing 96 yeast genes from Operon. Two-colour hybridizations with labelled cDNA target pools derived from standard grown and heat-shocked wild type yeast cells could reproducibly measure heat shock induced expression of seven different heat shock protein (HSP) genes. Moreover, the observed fold changes were comparable to those reported previously using spotted cDNA arrays and high-density 25-mer oligonucleotide arrays from Affymetrix. The low hybridization signals obtained from the Δ SSA4 mutant cDNA target, together with the high signal detected in two-colour hybridizations with heat-shocked wild type yeast relative to the Δ SSA4 mutant strain implies that unspecific binding of cDNA target to the SSA4-specific 70-mer oligonucleotide probes is negligible. Combined, our results indicate that the coated polymer microarray slide represents a robust and cost-effective array platform for pre-spotted oligonucleotide arrays.

Rishi, A. S., N. D. Nelson, et al. (2004). "Genome walking of large fragments: an improved method." *Journal of Biotechnology* **111**(1): 9.

<http://www.sciencedirect.com/science/article/B6T3C-4CC7WVX-6/2/267b1f79a8e1db483295394a168aceb3>

The PCR-based genome walking method has been commonly used to isolate upstream regions from known cDNA sequences. The limitation of this technique is based on the location of the restriction site upstream to the gene-specific primer in the genome; hence, different restriction enzymes have to be used to isolate larger upstream fragments. In this paper, we present the advantageous use of partial and size-selected DNA as templates for genome walking, in isolating

larger upstream fragments. We have successfully tested this approach to isolate larger upstream fragments using the FailSafe(TM) PCR System. Use of partial digestion and size selection can provide better chances in obtaining larger flanking regions of known DNA sequence, when compared to use of total digested DNA.

Sentinelli, F., S. Lovari, et al. (2000). "A simple method for non-radioactive PCR-SSCP using MDE(TM) gel solution and a midi gel format: Application for the detection of variants in the GLUT1 and CTLA-4 genes." Journal of Biotechnology **78**(2): 201.

<http://www.sciencedirect.com/science/article/B6T3C-3YTJKWB-C/2/2d633a9f26de1a00f8f9fc85542a92a3>

The need to identify disease-causing mutations and DNA polymorphisms has increased with the continuing identification of new candidate genes. PCR single-strand conformation polymorphism (PCR-SSCP) is one of the techniques most widely used to identify a mutant sequence or a polymorphism in a known gene. However, the original SSCP protocols using the incorporation of radioactive label and polyacrylamide gel electrophoresis on sequencing gels for detection were labour intensive and time-consuming. Here we describe a simple SSCP protocol using MDE(TM) gel solution and a midi gel format to detect SSCP variations in the glucose transporter gene GLUT1, that we have previously analysed with the standard radioactive SSCP protocol, and we have also tested this method on the previously described point mutation (A/G transition in exon 1) of the CTLA-4 (cytotoxic T lymphocyte associated-4) gene. All known variants were detected. Based on the results, this technique appears to be simple, with no use of radioactive labels and with easy handling of the gel. Furthermore, it needs little optimisation, is relatively rapid and highly sensitive. We propose this method for the first screening for candidate gene variants.

Song, J. K., M. K. Kim, et al. (1999). "Cloning and expression of the gene encoding phospholipase A1 from *Serratia* sp. MK1 in *Escherichia coli*." Journal of Biotechnology **72**(1-2): 103.

<http://www.sciencedirect.com/science/article/B6T3C-3WNNMH42-B/2/bda75e276cf2918f6ce72faa372ba56e>

The gene encoding extracellular phospholipase A1 of *Serratia* sp. MK1 was cloned from a genomic DNA library. Formation of transparent halos on the PCY agar plates was used to identify *E. coli* carrying the phospholipase A1 gene. A 4.2 kb *EcoRI* fragment was isolated and sequenced. From nucleotide sequences and expression of various plasmids, two open reading frames (*plaA* and *plaS*) involved in efficient expression of phospholipase A1 in natural and recombinant host were identified. Extracellular phospholipase A1 activity was identified as the gene product of *plaA* encoding 321 amino acids with a predicted MW of 33400. Analysis of the amino acid sequence revealed significant homology (around 70%) to phospholipase A1 of *Serratia liquefaciens* and *Yersinia enterocolitica*. The sequence, -Gly-X1-Ser-X2-Gly-, known as a lipase-specific consensus sequence was also found in the bacterial phospholipase A1. *PlaS* encoding a protein of 224 amino acids showed no enzymatic activity, but might be necessary for the efficient expression of phospholipase A1 in *E. coli*. To further improve the production of phospholipase A1 as a soluble and active form in *E. coli*, the effect of some parameters was examined. Surprisingly, a higher yield of soluble and active phospholipase A1 could be obtained under the combined conditions of a lower temperature, an enriched medium, and a lower-strength promoter.

Su, W., S. Song, et al. (2003). "Multiplex polymerase chain reaction/membrane hybridization assay for detection of genetically modified organisms." Journal of Biotechnology **105**(3): 227.

<http://www.sciencedirect.com/science/article/B6T3C-49P498R-1/2/7260c2aa61eaf59939996c6e0941db0e>

To improve detection efficiency and result accuracy, four screening primer pairs, four identifying primer pairs, one common primer pair and corresponding probes were designed for the development of multiplex polymerase chain reaction/membrane hybridization assay (MPCR-MHA) for detection of the foreign genes insert in genetically modified organisms (GMOs). After detecting condition and parameter were optimized and determined, MPCR reactions were developed for amplifying several target genes simultaneously in one tube. Primers were labeled with biotin at the 5'-end; biotinylated MPCR products were detected by hybridization to the oligonucleotide probes immobilized on a membrane with subsequent colorimetric detection to confirm hybridization. The testing of screening primers can judge whether the sample contains GMOs, and that of identifying primers can further judge what kinds of trait genes are contained in the sample. We detected nine soybean samples, six maize samples, seven potato samples and two rice samples by the MPCR-MHA method; at the same time we also detected them with single PCR-MHA method. The results between two methods have good consistency.

Tanaka, R., M. Mizukami, et al. (2003). "Cloning and expression of the ccdA-associated thiol-disulfide oxidoreductase (catA) gene from *Brevibacillus choshinensis*: stimulation of human epidermal growth factor production." Journal of Biotechnology **103**(1): 1.

<http://www.sciencedirect.com/science/article/B6T3C-48GVVH3-6/2/cf8c06067d9f1b51e7d6e746e4eb84f1>

Brevibacillus choshinensis (*Bacillus brevis*) is a protein-hyperproducing bacterium with a useful host-vector system for the production of recombinant proteins. Here, we cloned the ccdA-catA ("height="11" width="9">cdA associated thioredoxin-like thiol-disulfide oxidoreductase) locus of *B. choshinensis* HPD31-S5. CatA protein (molecular weight, 19664) contains a thioredoxin-like motif, Cys-Gly-Pro-Cys. It was successfully expressed in *B. choshinensis* extracellularly (~100 [μ]g ml⁻¹ culture) using the secretion vector pNCMO2, and in *Escherichia coli* intracellularly (~350 [μ]g ml⁻¹ culture) with an amino-terminal His-tag. Both recombinant proteins showed thiol-disulfide oxidoreductase activity. Incubation of non-native human epidermal growth factor (hEGF) containing incorrect disulfide bonds with *B. choshinensis* cells secreting CatA protein resulted in the stimulation of the conversion of non-native hEGF to the native form. Furthermore, co-expression of CatA protein with recombinant hEGF in the *B. choshinensis* production system increased the yield of native hEGF.

Uchide, T., J. Adur, et al. (2000). "Rapid quantification of murine endothelin-1 and vasoactive intestinal contractor gene expression levels by a real-time PCR system." Journal of Biotechnology **84**(2): 187.

<http://www.sciencedirect.com/science/article/B6T3C-41PNYNT-B/2/f46de637f24478cee1413c577f222161>

A rapid quantitative analysis method for murine endothelin-1 (ET-1) and vasoactive intestinal contractor (VIC) gene expression levels was established using a real-time polymerase chain reaction (PCR). We designed primer pairs and TaqMan probes specific for murine prepro-ET-1 (PPET-1) and prepro-VIC (PPVIC) genes, based on the cDNA sequence region common to both

mouse and rat. The dynamic range for detection in this system spanned 100000-fold of the starting molecule. The gene expression levels of PPET-1 and PPVIC were estimated as gene expression rates normalized by the expression of the house-keeping gene, glyceraldehyde-3-phosphate dehydrogenase. To examine the reproducibility of this assay system, we calculated the intra-assay and interassay coefficients of variation of the gene expression rate, which ranged from 16.2 to 55.0% and from 24.2 to 56.5%, respectively. Using this system, we examined gene expression levels of PPET-1 and PPVIC in mouse tissues. PPET-1 gene expression was found in all tissues at relatively high levels, whereas high levels of PPVIC gene expression were observed only in stomach, intestine, uterus, and ovary. The gene expression patterns agreed well with those determined by RNase protection assay and conventional PCR. These results show that this new rapid method is accurate and reproducible.

Wong, L. Y., A. Hafeman, et al. (2003). "Assessing gene expression variation in normal human tissues using GeneTag(TM), a novel, global, sensitive profiling method." Journal of Biotechnology **101**(3): 199.

<http://www.sciencedirect.com/science/article/B6T3C-47XSY7N-1/2/e186b5386c9d84fc14fc9fc7c5d8c98d>

GeneTag(TM) is a novel expression profiling method that allows the visualization, quantification and identification of expressed genes--whether known or novel--in any species, tissue or cell type, independent of knowledge of the underlying sequence. Here we describe the application of this method to determine variation of gene expression in individual human liver samples and the identification of tissue-specific genes by comparing expression patterns across several human organs. Expression data are stored in a database for future reference and data analysis relies on proprietary software, which allows complex comparisons to be performed. Differentially expressed genes are quickly identified through a link to a sequence database. The results from our study underscore the importance of knowledge of individual variation of gene expression for the design and interpretation of transcript profiling experiments in the context of any biological question.

Yoza, B., A. Arakaki, et al. (2003). "DNA extraction using bacterial magnetic particles modified with hyperbranched polyamidoamine dendrimer." Journal of Biotechnology **101**(3): 219.

<http://www.sciencedirect.com/science/article/B6T3C-47XFYR8-1/2/1f7a9843f20e768ea87edf2a7d008265>

A cascading hyperbranched polyamidoamine dendrimer was synthesized on the surface of bacterial magnetite from *Magnetospirillum magneticum* AMB-1 to allow enhanced extraction of DNA from fluid suspensions. Characterization of the synthesis revealed linear doubling of the surface amine charge from generations one through five starting with an amino silane initiator. Furthermore, transmission electron microscopy revealed clear dispersion of the single domain magnetite in aqueous solution. The dendrimer modified magnetic particles have been used to carry out magnetic separation of DNA. Binding and release efficiencies increased with the number of generations and those of bacterial magnetite modified with six generation dendrimer were 7 and 11 times respectively as many as those of bacterial magnetite modified with only amino silane.

Bausch, S. B., T. A. Patterson, et al. (1995). "Immunocytochemical localization of delta opioid receptors in mouse brain." Journal of Chemical Neuroanatomy **8**(3): 175.

<http://www.sciencedirect.com/science/article/B6T02-4031TYD-8/2/8567071b43de4653bd9dae2bcfde1333>

An affinity-purified anti-peptide antibody generated against the carboxy-terminal region of the [delta] opioid receptor was used to localize [delta] opioid receptors in mouse brain. [delta] Opioid receptor immunoreactivity was found in axons and nerve terminals in regions of the olfactory bulb, hippocampal formation, cerebral and cerebellar cortex, midbrain and hindbrain. The immunocytochemical distribution correlated well, though not completely with autoradiographic distribution of [delta] opioid receptors in mouse brain using either [3H][2--penicillamine, 5--penicillamine]-enkephalin (DPDPE) or [3H]naltrindole. Confocal microscopy of double-labeled tissue provided direct evidence that [delta] opioid receptors are principally expressed on GABAergic terminals in the hippocampus. These anatomical findings complement extensive physiological studies to provide a more detailed description of endogenous opioid circuitry.

Phillips, J. K., R. Dubey, et al. (2001). "Differential expression of the noradrenaline transporter in adrenergic chromaffin cells, ganglion cells and nerve fibres of the rat adrenal medulla." Journal of Chemical Neuroanatomy **21**(1): 95.

<http://www.sciencedirect.com/science/article/B6T02-429Y5BB-7/2/119d8d4a9815fa1f124dcb8153ef6c3e>

Expression of the noradrenaline transporter (NAT) was identified in various cell and fibre populations of the rat adrenal medulla, examined with immunohistochemistry and confocal microscopy. Immunoreactivity for the catecholamine biosynthetic enzymes tyrosine hydroxylase (TH), aromatic--amino-acid decarboxylase (AADC) and dopamine [beta]-hydroxylase (DBH) was present in all chromaffin cells, while phenylethanolamine N-methyltransferase (PNMT) was used to determine adrenergic chromaffin cell groups. Labelling with NAT antibody was predominantly cytoplasmic and colocalised with PNMT immunoreactivity. Noradrenergic chromaffin cells were not NAT immunoreactive. Additionally, NAT antibody labelling demonstrated clusters of ganglion cells (presumably Type I) and nerve fibres. Expression of TH, AADC, DBH, PNMT and NAT mRNA was examined using reverse transcription-polymerase chain reaction (RT-PCR) from adrenal medulla punches and single chromaffin cells, and results were consistent with those obtained with immunocytochemistry. Chromaffin cells and fibres labelled with antibodies against growth associated protein-43 (GAP-43) were not NAT immunoreactive, while ganglion cells were doubly labelled with the two antibodies. The presence of NAT in adrenergic chromaffin cells, and its absence from noradrenergic cells, suggests that the adrenergic cell type is primarily responsible for uptake of catecholamines in the adrenal medulla.

Ray, S. K., D. D. Matzelle, et al. (2003). "Calpain inhibitor prevented apoptosis and maintained transcription of proteolipid protein and myelin basic protein genes in rat spinal cord injury." Journal of Chemical Neuroanatomy **26**(2): 119.

<http://www.sciencedirect.com/science/article/B6T02-497RH1S-2/2/8b5f9df77927f895786c540839a25562>

Spinal cord injury (SCI) is associated with progressive neurodegeneration and dysfunction. Multiple cellular and molecular mechanisms are involved in this pathogenesis. In particular, the activation of proteases following trauma can cause apoptosis in the spinal cord. Calpain, a calcium-dependent cysteine protease, plays a major role in apoptosis following trauma. We identified apoptosis and decrease in transcription of the genes for proteolipid protein (PLP) and myelin basic protein (MBP) in five 1-cm long spinal cord segments (S1, distant rostral; S2, near rostral; S3, lesion; S4, near caudal; and S5, distant caudal) 24 h after induction of SCI (40 g.cm force) in rats by weight-drop method. Sham rats underwent laminectomy and did not receive injury. Internucleosomal DNA fragmentation occurred prominently in the lesion (S3), moderately in near segments (S2 and S4), and slightly in distant segments (S1 and S5) of injured rats, indicating the occurrence of apoptosis in the lesion and penumbra. Levels of transcription of PLP and MBP were reduced highly in the lesion and moderately in near segments, suggesting that apoptotic loss of cells impaired biosynthesis of two important structural components of myelin. Immediate administration of the calpain inhibitor E-64-d (1 mg/kg) to injured rats prevented apoptosis and restored transcription of these genes, indicating the therapeutic efficacy of calpain inhibitor for treatment of SCI.

Journal of Chromatography A (16)

Arakawa, H., S. Nakashiro, et al. (1996). "Analysis of single-strand DNA conformation polymorphism by capillary electrophoresis." Journal of Chromatography A **722**(1-2): 359.

<http://www.sciencedirect.com/science/article/B6TG8-3THM8DC-1G/2/72be2fc82a989a8001500bdaccf37886>

Analysis of single-strand conformation polymorphism (SSCP) by capillary electrophoresis (CE) was developed. The conformational change of single-strand DNA is caused by a mutation in a DNA fragment. The change is detected as mobility shift in CE. The effects of acrylamide gel concentration, running temperature and fragment size amplified by the polymerase chain reaction (PCR) were studied to develop the separation of SSCP. The model DNA used was the divE 42 gene carrying wild- and mutant-type (G->A point mutation at the 141 site). The results show that two single-strand DNA fragments that differ in one nucleotide can be separated by CE within minutes. This method was also applied to the separation of SSCP for N-ras gene including four kinds of mutations. All mutations tested in this study could be distinguished. CE is well suited for clinical analysis of SSCP because it is rapid and reproducible, allows on-line detection and is easy.

Arakawa, H., K. Uetanaka, et al. (1994). "Analysis of polymerase chain reaction product by capillary electrophoresis and its application to the detection of single base substitution in genes." Journal of Chromatography A **664**(1): 89.

<http://www.sciencedirect.com/science/article/B6TG8-44CPVGG-VF/2/9104831ae627cefb4b8c28e59bab3d2c>

Capillary gel electrophoresis (CGE) was studied for the direct analysis of polymerase chain reaction (PCR) amplified samples. A low cross-linked polyacrylamide gel (3%T, 0.5%C) was used for CGE with treated and untreated silica capillaries. CGE showed high reproducibility and

resolution in the separation of DNA fragments (ca. 100-1000 base pairs) produced by PCR. The CGE system was applied to the detection of an amplification refractory mutation system (ARMS) and PCR--restriction fragment length polymorphism (PCR-RFLP), which are detection methods of single base substitution in genes using PCR. With the CGE system, full automation of PCR product detection is feasible.

Arakawa, H., K. Uetanaka, et al. (1994). "Analysis of polymerase chain reaction-product by capillary electrophoresis with laser-induced fluorescence detection and its application to the diagnosis of medium-chain acyl-coenzyme A dehydrogenase deficiency." Journal of Chromatography A **680**(2): 517.

<http://www.sciencedirect.com/science/article/B6TG8-44CPS94-50/2/e05a0e94df4fc24ccd7db73cdb19d223>

Capillary gel electrophoresis with laser-induced fluorescence (CGE-LIF) has been developed to detect polymerase chain reaction (PCR) amplified samples. LIF detection was performed using Thiazole Orange as the fluorescent intercalating dye. This method was ca. 100X as sensitive as that with UV detection. The highly sensitive CGE-LIF was applied to the detection of the most prevalent mutation (lysine329- to-glutamic acid substitution) in medium-chain acyl-coenzyme A dehydrogenase (MCAD) deficiency. The disorder, which shows an autosomal recessive inheritance, is known to be highly prevalent among Caucasian population and often mimics as Reye-like syndrome or sudden infant death. A DNA fragment containing the mutation site was PCR-amplified with two sets of allele specific oligonucleotide primers, followed by CGE-LIF. The mutant allele produced a 175-base pairs DNA fragment, which the normal allele generated a 202-base pairs DNA fragment. CGE-LIF clearly distinguished these PCR products, facilitating rapid diagnosis of MCAD deficiency.

Bencina, M., K. Bencina, et al. (2005). "Immobilization of deoxyribonuclease via epoxy groups of methacrylate monoliths: Use of deoxyribonuclease bioreactor in reverse transcription-polymerase chain reaction." Journal of Chromatography A **1065**(1): 83.

<http://www.sciencedirect.com/science/article/B6TG8-4DTP23H-5/2/ec22cdec0f6a9f1930c2dc59f26f14b3>

A deoxyribonuclease bioreactor was prepared by immobilization of deoxyribonuclease I through epoxy groups inherently present on poly (glycidyl methacrylate-co-ethylene dimethacrylate) monoliths. Columns with various levels of DNase activity were prepared varying immobilization temperature, pH, time and method. The apparent Michaelis-Menten constant, and turnover number, for immobilized DNase determined by on-line frontal analysis method were, respectively, 0.28 g of DNA I-1 and 16 dA260nm min⁻¹ mg⁻¹ of immobilized DNase. The highest activity of immobilized DNase was detected at 1 mM calcium ions concentration and mirrored properties of free enzyme; however, reaction temperature in the range from 25 to 37 [deg]C has no significant effect on activity of immobilized DNase in contrary to free enzyme. The CIM DNase bioreactor was used for elimination of DNA contaminants in RNA samples prior to reverse transcription followed by PCR.

Branovic, K., D. Forcic, et al. (1999). "Introduction of the gene amplification technique to decrease the risk of hepatitis C virus transmission by plasma products." Journal of Chromatography A **852**(1): 305.

<http://www.sciencedirect.com/science/article/B6TG8-3YN2XK4-14/2/a48cb46561f28a669d6b1b183981074d>

The viral safety of plasma-derived products with respect to hepatitis C virus (HCV) is assured by selection of donors, screening of individual donations for antibodies to HCV and the incorporation of effective viral inactivation-removal steps into manufacturing processes. As antibody screening of single donations is not sufficient to completely eliminate HCV RNA positive plasmas from plasma pools, testing for HCV RNA by gene amplification techniques may be necessary to identify positive donations. Using modern molecular biology techniques, we developed a specific, sensitive and reproducible method for routine PCR screening for HCV RNA in plasma pools.

Chiang, L. W. (1998). "Detection of gene expression in single neurons by patch-clamp and single-cell reverse transcriptase polymerase chain reaction." Journal of Chromatography A **806**(1): 209.

<http://www.sciencedirect.com/science/article/B6TG8-3SR91XC-1V/2/bc65daf8b49813dfaf00423d43030c92>

Detection and quantitation of gene expression in single cells is especially important in the central nervous system where, at the cellular level, the synapse can be considered the single functional unit. For example, the consolidation of long-term memories may be mediated by persistent changes in the strength of synaptic transmission at individual synapses. In order to investigate the requirement for de novo RNA synthesis during long-term potentiation in individual neurons, we have combined single-cell electrophysiology with single-cell gene-expression methodology. Described are methods combining whole-cell patch-clamp and single-cell RT-PCR for the detection of a single mRNA species for nitric oxide synthase, or, through a multiplex strategy, for the simultaneous detection of several mRNAs including heme oxygenase 2, protein phosphatase inhibitor 1 protein, and several isoforms of the calcium/calmodulin dependent protein kinase II.

Deforce, D. L. D., R. E. M. Millecamps, et al. (1998). "Comparison of slab gel electrophoresis and capillary electrophoresis for the detection of the fluorescently labeled polymerase chain reaction products of short tandem repeat fragments." Journal of Chromatography A **806**(1): 149.

<http://www.sciencedirect.com/science/article/B6TG8-3SR91XC-1M/2/5c7b5e14d1606e80c9e344cb7380aaf1>

The sizing capability of slab gel electrophoresis for short tandem repeat (STR) fragments was compared to the sizing capability of capillary electrophoresis (CE). Both systems used automated laser fluorescence detection to detect four fluorescent dyes, enabling the use of an internal lane standard within each sample. The STR fragments were amplified using a multiplex polymerase chain reaction (PCR) in which the STR fragments Hum CD-4, Hum TH01, Hum D21S11 and Hum SE33 were amplified simultaneously. The reproducibility of the size calling was determined for both systems. The average standard deviation obtained for the slab gel system was 0.2, which was comparable to the standard deviation of 0.12 obtained for the CE system. The CE system produced results comparable to those obtained on the slab gel system, with a level of precision of +/-1.0 bp (between instruments).

Del Principe, D., M. Paola Iampieri, et al. (1993). "Analysis of a polymerase chain reaction-amplified product of the DXS 164 locus in the dystrophin gene: Detection by capillary electrophoresis of restriction fragment length polymorphism." Journal of Chromatography A **638**(2): 277.

<http://www.sciencedirect.com/science/article/B6TG8-44GP787-2K/2/e2445ee2e253337583374122eba5db2e>

Capillary electrophoresis (CE) was used to characterize restriction fragment length polymorphism (RFLP) in a polymerase chain reaction (PCR)-amplified product of a 740-base pairs DNA fragment from the DXS 164 locus of the dystrophin gene. The polymorphic alleles of 740 and 520/220 base pairs revealed by XmnI digestion were analysed from homozygous and heterozygous individuals by CE. Our studies show that extraction in phenol-chloroform may be useful in PCR-amplified product purification. Excellent separation was obtained in a short time. The data indicate that CE is suitable for genomic analysis such as carrier detection and prenatal diagnosis of X-linked recessive disorders after purification of PCR-amplified products.

Fung, E. N., H.-m. Pang, et al. (1998). "Fast DNA separations using poly(ethylene oxide) in non-denaturing medium with temperature programming." *Journal of Chromatography A* **806**(1): 157.

<http://www.sciencedirect.com/science/article/B6TG8-3SR91XC-1N/2/c86efdf80851206a0e60c2a71ae2f0ae>

We demonstrated fast DNA separations in low viscosity entangled solutions with a temperature gradient in a non-denaturing separation medium. The separations were carried out in a solution of commercially available poly(ethylene oxide) (PEO) [1 x Tris(hydroxymethyl)aminomethane borate buffer, without urea] with a temperature gradient of 2[deg]C/min. The performance was compared with that of a solution of PEO with urea at ambient temperature. We found that the former condition gives sufficient resolution for accurate base calling and that in general, it gave better separation for fragments larger than 450 base pairs (bp). Most importantly, the separation speed approaches 30 bp/min. In addition, we describe a simple yet reliable gel preparation protocol for such separations.

Hadd, A. G., M. P. Goard, et al. (2000). "Sub-microliter DNA sequencing for capillary array electrophoresis." *Journal of Chromatography A* **894**(1-2): 191.

<http://www.sciencedirect.com/science/article/B6TG8-41C28J6-T/2/ad27d1770fd7bd9f574853cb13bb85fe>

DNA sequencing from sub-microliter samples was demonstrated for capillary array electrophoresis by optimizing the analysis of 500 nl reaction aliquots of full-volume reactions and by preparing 500 nl reactions within fused-silica capillaries. Sub-microliter aliquots were removed from the pooled reaction products of 10 [mu]l dye-primer cycle-sequencing reactions and analyzed without modifying either the reagent concentrations or instrument workflow. The impact of precipitation methods, resuspension buffers, and injection times on electrokinetic injection efficiency for 500 nl aliquots were determined by peak heights, signal-to-noise ratios, and changes in base-called readlengths. For 500 nl aliquots diluted to 5 [mu]l in 60% formamide-1 mM EDTA and directly injected, a five-fold increase in signal-to-noise ratios was obtained by increasing injection times from 10 to 80 s without a corresponding increase in peak widths or reduction in readlengths. For 500 nl aliquots precipitated in alcohol, 80+/-5% template recovery and a two-fold decrease in conductivity was obtained, resulting in a two-fold increase in peak heights and 50 to 100 bases increase in readlengths. In a comparison of aliquot volumes and precipitation methods, equivalent readlengths were obtained for 500 nl, 4 [mu]l, and 8 [mu]l aliquots by simply adjusting the electrokinetic injection conditions. To ascertain the robustness of this methodology for genomic sequencing, 96 Arabidopsis thaliana subclones were sequenced, with a yield of 38624 bases obtained from 500 nl aliquots versus 30764 bases from standard

scale reactions. To demonstrate 500 nl sample preparation, reactions were performed in fused-silica capillary reaction chambers using air-based thermal cycling. A readlength of 690 bases was obtained for the polymerase chain reaction product of an Arabidopsis subclone without modifying the reagent concentrations, post-reaction processing or electrokinetic injection workflow. These results demonstrated the fundamental feasibility of small-volume DNA sequencing for high-throughput capillary electrophoresis.

Inoue, H., M. Tsuchiko, et al. (1998). "Enhanced separation of DNA sequencing products by capillary electrophoresis using a stepwise gradient of electric field strength." Journal of Chromatography A **802**(1): 179.

<http://www.sciencedirect.com/science/article/B6TG8-3SHJH9D-R/2/81c7e3866e95773745a9e5edb602a65a>

The effect of the electric field strength gradient on the separation of DNA sequencing fragments was investigated. We demonstrate that the stepwise gradient of electric field improves the separation of DNA sequencing fragments more than 500 bases in size and diminishes the analysis time for DNA sequencing of larger DNA fragments. The use of the electric field strength gradient induces an increase in the theoretical plate number as predicted by the theoretical formulation discussed in this paper.

Katsuragi, K., K. Kitagishi, et al. (1996). "Fluorescence-based polymerase chain reaction-single-strand conformation polymorphism analysis of p53 gene by capillary electrophoresis." Journal of Chromatography A **744**(1-2): 311.

<http://www.sciencedirect.com/science/article/B6TG8-3VB3P64-3P/2/11696f64a02b101efaae42a0f242bdf7>

Mutation of the p53 gene plays an important role in neoplastic progression in human tumorigenesis. Polymerase chain reaction-single-strand conformation polymorphism (PCR-SSCP) techniques are now available for the detection of point mutations. The original method using polyacrylamide gel electrophoresis is disadvantageous, particularly for clinical tests and for analysis of large numbers of samples. Therefore, using an automated capillary electrophoresis (CE) technique with a molecular-sieving polymer solution, we have devised a completely automatic fluorescence-based PCR-SSCP system (CE-FSSCP) for the differential detection of point mutations that does not require SSCP with radioisotopes and polyacrylamide gels. This automatic CE-FSSCP system was developed for reproducible operations in the denaturation of double-stranded DNA and electrophoresis of single-stranded DNA. The detection system consists of a 100 W I2 lamp and photomultiplier. We performed CE-FSSCP with a 2% linear polyacrylamide polymer solution containing 5% glycerol. Four tissue specimens of lung tumors with mutations in exon 7 of the p53 gene were found to have mutant alleles; a six-base-pair deletion at codons 247-248, a one-base-pair deletion at codon 260, a one-base-pair deletion at codon 244 and a GGC to CGC substitution at codon 244. We expect this technique to prove useful for the clinical DNA diagnosis of human cancers, determination of the therapeutic effect of anticancer agents and for the study of the molecular aspects of the mechanisms involved in the pathogenesis of human cancers.

Kim, Y. and E. S. Yeung (1997). "Separation of DNA sequencing fragments up to 1000 bases by using poly(ethylene oxide)-filled capillary electrophoresis." Journal of Chromatography A **781**(1-2): 315.

<http://www.sciencedirect.com/science/article/B6TG8-3SDKTD6-17/2/0966f83ca92c48ae0b0634fbda55d3ce>

We have demonstrated that DNA bases up to 1000 base pairs (bp) in a sequencing ladder can be separated using poly(ethylene oxide)-filled capillary electrophoresis (resolution of raw data=0.5 at 966 bp). Separation performance of this sieving matrix has been tested under different experimental conditions. It was found that the electric field strength played a critical role in the onset of reptation and thus the separation efficiency. Optimized gel composition and concentration is required for good separation, but the total gel concentration should lie between 2.5 and 3.0%. We observed that the capillary length influences the number of theoretical plates and the maximum readable length of DNA. For sequencing up to 500 bp, relatively nonviscous solutions can be used, greatly facilitating the replacement of the sieving matrix in between runs.

Pigge, C. A., J. Muth, et al. (1997). "Capillary electrophoresis for the detection of known point mutations by single-nucleotide primer extension and laser-induced fluorescence detection." Journal of Chromatography A **781**(1-2): 367.

<http://www.sciencedirect.com/science/article/B6TG8-3SDKTD6-1D/2/8a8a6d6bfd0150bb895b3a2283321aba>

Capillary electrophoresis (CE) with laser-induced fluorescence (LIF) was used to detect known point mutations using the method of single-nucleotide primer extension (SNUPE). Three different point mutations in human mitochondrial DNA associated with Leber's hereditary optic neuropathy (LHON) were detected by annealing a primer immediately 5' to the mutation on the template and extending the primer by one fluorescently labeled dideoxy terminator complementary to the mutation. By using two or more differently labeled terminators, both the mutant and wild type could be simultaneously detected. The advantages of using CE-LIF for detecting SNUPE reactions include speed and ease of analysis, absence of radioactivity, and potential for automation.

Song, L., D. Liang, et al. (2001). "DNA sequencing by capillary electrophoresis using mixtures of polyacrylamide and poly(N,N-dimethylacrylamide)." Journal of Chromatography A **915**(1-2): 231.

<http://www.sciencedirect.com/science/article/B6TG8-42RDRV4-V/2/23554d243b90dd519165915fbc90a4ba>

The possibility of using polymer mixtures with different chemical compositions as a DNA sequencing matrix by capillary electrophoresis (CE) has been exploited. Polyacrylamide (PAM, 2.5%, w/v) having a molecular mass of 2.2.10⁶ has been mixed with poly(N,N-dimethylacrylamide) (PDMA) having molecular masses of 8000, 470000 and 2.1.10⁶ at concentrations of 0.2, 0.5 and 1% (w/v). Unlike polymer mixtures of the same polymer with different molecular masses, the use of polymer mixtures with different chemical compositions encounters an incompatibility problem. It was found that the incompatibility increased with increasing PDMA molecular mass and PDMA concentration, which resulted in decreased efficiency in DNA sequencing. Also, the incompatibility had a more pronounced effect on the efficiency as the base number was increased. However, by choosing a low-molecular-mass PDMA of 8000 and a low concentration of 0.2% (w/v), the incompatibility of PAM and PDMA has been alleviated. At the same time, the advantage of using polymer mixtures revealed a higher efficiency for such a polymer mixture when compared with PAM. The mixture also endowed the separation medium with a dynamic coating ability. An efficiency of over 10.10⁶ theoretical plates per meter has been achieved by using the bare capillaries without the additional chemical coating

step.

Soper, S. A., S. M. Ford, et al. (1999). "Nanoliter-scale sample preparation methods directly coupled to polymethylmethacrylate-based microchips and gel-filled capillaries for the analysis of oligonucleotides." Journal of Chromatography A **853**(1-2): 107.

<http://www.sciencedirect.com/science/article/B6TG8-3X64GMY-F/2/2af1f44dfc2c5f321186c1f17011334f>

We are currently developing miniaturized, chip-based electrophoresis devices fabricated in plastics for the high-speed separation of oligonucleotides. One of the principal advantages associated with these devices is their small sample requirements, typically in the nanoliter to sub-nanoliter range. Unfortunately, most standard sample preparation protocols, especially for oligonucleotides, are done off-chip on a microliter-scale. Our work has focused on the development of capillary nanoreactors coupled to micro-separation platforms, such as micro-electrophoresis chips, for the preparation of sequencing ladders and also polymerase chain reactions (PCRs). These nanoreactors consist of fused-silica capillary tubes (10-20 cm x 20-50 [μm] I.D.) with fluid pumping accomplished using the electroosmotic flow generated by the tubes. These reactors were situated in fast thermal cyclers to perform cycle sequencing or PCR amplification of the DNAs. The reactors could be interfaced to either a micro-electrophoresis chips via capillary connectors micromachined in polymethylmethacrylate (PMMA) using deep X-ray etching (width 50 [μm]; depth 50 [μm]) or conventional capillary gel tubes using zero-dead volume glass unions. For our chips, they also contained an injector, separation channel (length 6 cm; width 30 [μm]; depth 50 [μm]) and a dual fiber optic, near-infrared fluorescence detector. The sequencing nanoreactor used surface immobilized templates attached to the wall via a biotin-streptavidin-biotin linkage. Sequencing tracks could be directly injected into gel-filled capillary tubes with minimal degradation in the efficiency of the separation process. The nanoreactor could also be configured to perform PCR reactions by filling the capillary tube with the PCR reagents and template. After thermal cycling, the PCR cocktail could be pooled from multiple reactors and loaded onto a slab gel or injected into a capillary tube or microchip device for fractionation.

de Carlos, A., D. Montenegro, et al. (2003). "Purification of human alpha-fucosidase precursor expressed in Escherichia coli as a glutathione S-transferase fusion protein." Journal of Chromatography B **786**(1-2): 7.

<http://www.sciencedirect.com/science/article/B6X0P-46X8XN2-3/2/14c7cb7608dc310e9f52efab581dac97>

Alpha-fucosidase (FUC) is a glycosidase involved in the degradation of fucose-containing glycoconjugates. A cDNA representing the complete sequence of human FUC was inserted into the prokaryotic expression vector pGEX-2T. High levels of the glutathione S-transferase (GST) fusion protein were detected in Escherichia coli cells after induction with isopropyl thio-beta-galactopyranoside. The GST-FUC protein was mostly found as inclusion bodies and attempts to optimise its expression as a soluble form were unsuccessful. Nevertheless, the recombinant protein was purified by affinity chromatography on glutathione-sepharose and its fucosidase

activity was characterised. After thrombin cleavage of the GST tag, the FUC precursor protein was purified by electro-elution.

<http://www.sciencedirect.com/science/article/B6X0P-46FMKN4-2/2/05a178a664df754b1fca3f12fe848ee8>

The extent of the DNA methylation of genomic DNA as well as the methylation pattern of many gene-regulatory areas are important aspects with regard to the state of genetic information, especially their expression. There is growing evidence that aberrant methylation is associated with many serious pathological consequences. As genetic research advances, many different approaches have been employed to determine the overall level of DNA methylation in a genome or to reveal the methylation state of particular nucleotide residues, starting from semiquantitative methods up to new and powerful techniques. In this paper, the currently employed techniques are reviewed both from the point of view of their relevance in genomic research and of their analytical application. The methods discussed include approaches based on chromatographic separation (thin-layer chromatography, high-performance liquid chromatography, affinity chromatography), separation in an electric field (capillary electrophoresis, gel electrophoresis in combination with methylation-sensitive restriction enzymes and/or specific sequencing protocols), and some other methodological procedures (mass spectrometry, methyl accepting capacity assay and immunoassays).

<http://www.sciencedirect.com/science/article/B6X0P-49679S6-3/2/1cbbf7a1b8714ecbf56602e73163cb9d>

To explore if it is correlated in human tumor cells that the expression of LDH homologous gene and LDH isoenzymes, we used RT-PCR-SSCP technique to measure the relative expression of genes with homologous sequences. The combination of PCR using common primers designed in the highly conserved regions and single-strand conformation polymorphism analysis of the products is used for quantitative determination of the proportions of LDH-A mRNA in human cancer cell lines. The proportion is compared with that of the activities of isoenzymes. The results indicated that the enzyme activity of LDH-A was consistent with mRNA levels in the human tumor cell. The present procedure using a single pair of primers for two fragments can overcome disadvantages in quantitative analysis using multiplex PCR. Template concentrations and PCR cycles did not affect the proportions of LDH-A and LDH-B in the product.

Muhr, D., T. Wagner, et al. (2002). "Polymerase chain reaction fidelity and denaturing high-performance liquid chromatography." Journal of Chromatography B **782**(1-2): 105.

<http://www.sciencedirect.com/science/article/B6X0P-46W1CRX-C/2/a6fba080eda63a1a5c9ddbf705aa6c2>

Incorporation of non-complementary nucleotides during polymerase chain reaction can result in

ambiguous denaturing high-performance liquid chromatography profiles that reduce both sensitivity and specificity of mutation analysis. The use of proofreading DNA polymerases increases the fidelity of polymerase chain reaction and, consequently, reduces background noise in the chromatograms. This is demonstrated for several BRCA1 and BRCA2 mutations that had yielded previously chromatograms of poor quality using non-proofreading enzyme for amplification. Interestingly, despite the reduced level of background heteroduplexes, the ability of denaturing high-performance liquid chromatography to detect mutant alleles at a frequency <10% in pools of chromosomes did not improve significantly.

Oefner, P. J. and C. G. Huber (2002). "A decade of high-resolution liquid chromatography of nucleic acids on styrene-divinylbenzene copolymers." Journal of Chromatography B **782**(1-2): 27.

<http://www.sciencedirect.com/science/article/B6X0P-470M7NT-5/2/8eaa2ae4fc0066683bbf40f474bd9c8d>

The introduction of alkylated, nonporous poly-(styrene-divinylbenzene) microparticles in 1992 enabled the subsequent development of denaturing HPLC that has emerged as the most sensitive screening method for mutations to date. Denaturing HPLC has provided unprecedented insight into human origins and prehistoric migrations, accelerated the cloning of genes involved in mono- and polygenic traits, and facilitated the mutational analysis of more than a hundred candidate genes of human disease. A significant step toward increased sample-throughput and information content was accomplished by the recent introduction of monolithic poly(styrene-divinylbenzene) capillary columns. They have enabled the construction of capillary arrays amenable to multiplex analysis of fluorescent dye-labeled nucleic acids by laser-induced fluorescence detection. Hyphenation of denaturing HPLC with electrospray ionization mass spectrometry, on the other hand, has allowed the direct elucidation of the chemical nature of DNA variation and determination of phase of multiple alleles on a chromosome.

<http://www.sciencedirect.com/science/article/B6X0P-46DKYNB-2/2/c311c42e604e705e8bd70bdeb9dda2ed>

Optimization of electrophoretic techniques is becoming an increasingly important area of research as microdevices are now routinely adapted for numerous biology and engineering applications. The present work seeks to optimize electrophoresis within microdevices by utilizing ultra-high voltages to increase sample concentration prior to separation. By imaging fluorescently-tagged DNA samples, the effects of both conventional and atypical voltage protocols on DNA migration and separation are readily observed. Experiments illustrate that short periods of high voltage during electrophoretic injection do not destroy the quality of DNA separations, and in fact can enhance sample concentration five-fold. This study presents data that illustrate increases in average resolution, and resolution of longer fragments, obtained from electrophoretic injections utilizing voltages between 85 and 850 V/cm.

Zhao, C., G. Xu, et al. (2003). "Simultaneous genotyping of multiplex single nucleotide polymorphisms of the K-ras gene with a home-made kit." Journal of Chromatography B **795**(1): 55.

<http://www.sciencedirect.com/science/article/B6X0P-49D6GG6->

5/2/2e98b99a743539907a30c719c990ffec

Accurate and fast genotyping of single nucleotide polymorphisms (SNPs) is important in the human genome project. Here an automated fluorescent method that can rapidly and accurately genotype multiplex known SNPs was developed by using a homemade kit, which has lower cost but higher resolution than commercial kit. With this method, oncogene K-ras was investigated, four known SNPs of K-ras gene exon 1 in 31 colorectal cancer patients were detected. Results indicate that mutations were present in 8(26%) of 31 patients, and most mutations were localized in codon 12. The presence of these mutations is thought to be a critical step and plays an important role in human colorectal carcinogenesis.

Arakawa, H., S. Nakashiro, et al. (1998). "Analysis of polymerase chain reaction products by high-performance liquid chromatography with fluorimetric detection and its application to DNA diagnosis." Journal of Chromatography B: Biomedical Sciences and Applications **716**(1-2): 119.

<http://www.sciencedirect.com/science/article/B6TG9-3TWXX3J-F/2/4bcd3a2bd25c34364c42e63e3d324b76>

We describe the development of a sensitive high-performance liquid chromatographic (HPLC) method for polymerase chain reaction (PCR) products using bisbenzimidazole (Hoechst 33258 dye) based fluorimetric detection. The detection limit and specificity for double-strand DNA detection are improved in comparison with HPLC with UV absorbance detection. This HPLC, using a column packed with diethylaminoethyl-bonded non-porous resin particles, was applied to the detection of allele-specific PCR and restriction fragment length polymorphism analysis. We also developed a hybridization method analyzed by HPLC. DNA fragments (149 bp) containing the mutation site (C→A,G,T) in the N-ras gene were amplified by PCR. Fluorescein isothiocyanate (FITC)-labeled DNA probes were also prepared by PCR using FITC-labeled 5' primer. Analysis of mutation was performed by the separation of a hybrid and non-reactive DNA probe with HPLC with fluorimetric detection after the hybridization of target DNA (149 bp) and a FITC DNA probe. The effects of various factors on hybridization were examined to establish optimal assay conditions. Under the conditions determined, a point mutation in PCR products obtained from the N-ras gene could be detected specifically by this method. The analysis of PCR products by HPLC may potentially be useful for DNA diagnosis.

Belgrader, P., J. M. Devaney, et al. (1996). "Automated polymerase chain reaction product sample preparation for capillary electrophoresis analysis." Journal of Chromatography B: Biomedical Sciences and Applications **683**(1): 109.

<http://www.sciencedirect.com/science/article/B6TG9-3V9DKTF-D/2/7bef7f875bfae2ff4ad1577af1e715e8>

The analysis of crude polymerase chain reaction (PCR) products by capillary electrophoresis (CE) is often compromised due to the presence of a high concentration of salt. Salt interferes with the electrokinetic injection and induces localized heating within the column; hence, PCR products must be desalted or cleaned-up prior to CE analysis. A variety of commercial clean-up systems

are available that have been traditionally used to prepare PCR products for cloning, sequencing and digestion with restriction enzymes. These systems were tested for their effectiveness in preparing PCR products for CE analysis and were evaluated based on CE resolution, salt removal, DNA recovery, processing time and cost. One particularly effective clean-up system, membrane dialysis, was automated using a robotic workstation.

Butler, J. M., B. R. McCord, et al. (1994). "Quantitation of polymerase chain reaction products by capillary electrophoresis using laser fluorescence." Journal of Chromatography B: Biomedical Sciences and Applications **658**(2): 271.

<http://www.sciencedirect.com/science/article/B6TG9-457CV9F-NK/2/f89b7ab0576841826e0a63b0f0aed563>

In samples where the amount of DNA is limited, the polymerase chain reaction (PCR) can amplify specific regions of the DNA. A quantitative analysis of the PCR product would be desirable to ensure sufficient DNA is available for analysis. In this study, we examine the use of capillary electrophoresis (CE) with laser fluorescence detection for quantitation of PCR products. A coated open tubular capillary was used with a non-gel sieving buffer and a fluorescent intercalating dye to obtain results within 20 minutes. Using an internal standard, peak migration time was below 0.1% relative standard deviation (R.S.D.) with a peak area precision of 3% R.S.D. In comparison to quantitation by hybridization, (i.e., slot blot) and spectrophotometric analysis, capillary electrophoresis shows distinct advantages due to its ability to separate unincorporated primers and PCR byproducts from the targeted PCR product. The results demonstrate that CE can be used to monitor the quality and quantity of the PCR product.

Gong, X. and E. S. Yeung (2000). "Genetic typing and HIV-1 diagnosis by using 96 capillary array electrophoresis and ultraviolet absorption detection." Journal of Chromatography B: Biomedical Sciences and Applications **741**(1): 15.

<http://www.sciencedirect.com/science/article/B6TG9-4037929-2/2/a6327c53460a46ed95d6199ac7a1123d>

Current high-throughput approaches to the analysis of PCR products are based primarily on electrophoretic separation and laser-excited fluorescence detection. We show that capillary array electrophoresis can be applied to HIV-1 diagnosis and D1S80 VNTR genetic typing based simply on UV absorption detection. The additive contribution of each base pair to the total absorption signal provides adequate detection sensitivity for analyzing most PCR products. Not only is the use of specialized and potentially toxic fluorescent labels eliminated, but also the complexity and cost of the instrumentation are greatly reduced.

Liang, Q., P. A. Davis, et al. (2001). "High-performance liquid chromatography multiplex detection of two single nucleotide mutations associated with hereditary hemochromatosis." Journal of Chromatography B: Biomedical Sciences and Applications **754**(1): 265.

<http://www.sciencedirect.com/science/article/B6TG9-42MFDJP-13/2/db2c17567a9a8d1668d6deda412f5c53>

High-performance liquid chromatography (HPLC) has been applied to the multiplex detection of the two single nucleotide mutations commonly found in hereditary hemochromatosis (HH). HH is

associated with a major G to A transition at position 845 (mutation Cys282Tyr) and a minor C to G transition at position 187 (mutation His63Asp) in the cDNA of the HFE gene. Two detection assays were developed based on HPLC analysis of restriction fragment length polymorphism (RFLP) or single nucleotide extension (SNE) products following multiplex PCR amplification. RFLP genotypes the two sites as dsDNA fragments of different lengths generated by restriction enzymes Rsa I/Bcl I. SNE extends primers 5'-adjacent to the sites of interest with a dideoxynucleotide triphosphate (ddNTP) to generate extended ssDNA. The identity of the added ddNTP reveals the identity of the original possible mutation site(s). Application of these methods with HPLC analysis provides simple and reliable genotyping for HH and can be applied to other single nucleotide polymorphism studies.

Mischiati, C., G. Feriotto, et al. (1995). "Chromatography in DNA radiolabeling: Hands-off automation using a robotic workstation." Journal of Chromatography B: Biomedical Sciences and Applications **664**(2): 303.

<http://www.sciencedirect.com/science/article/B6TG9-4002HC1-8F2/2effe9bccf4578aa7f110e5556c35504>

The experiments described in the present paper were performed in order to determine whether the Biomek-1000 (Beckman Instruments, Fullerton, CA, USA) automated laboratory workstation can be used in a fully automated DNA labeling method followed by automated gravity-driven size exclusion purification of molecular probes. To this aim, we performed random oligodeoxyribonucleotide priming of a HIV-1 LTR probe that was used for molecular hybridization to Southern blotted polymerase chain reaction products. The results obtained demonstrate that the automatically labeled probe can be efficiently purified by automated and gravity-driven Sephadex G-50 chromatography, without any major changes in hybridization property. This robotic methodology can be used in several procedures employing radioisotope labeling.

Tomita, M., T. Okuyama, et al. (1996). "Application of capillary gel electrophoresis to the diagnosis of the aldehyde dehydrogenase 2 genotype." Journal of Chromatography B: Biomedical Sciences and Applications **685**(1): 185.

<http://www.sciencedirect.com/science/article/B6TG9-3VVMN7T-W/2/cc670e2e65309fe0a91a0d293229f76e>

This study dealt with the application of capillary gel electrophoresis (CGE) to diagnosis of the aldehyde dehydrogenase 2 (ALDH-2) genotype. Electrophoresis was performed on a low cross-linked polyacrylamide gel {3% T [g acrylamide + g Bis (N,N'-methylenebisacrylamide)], 0.5% C (g Bis/%T)} in 100 mM Tris-borate buffer (pH 8.3) at -10 KV with on-column UV detection (260 nm). During the PCR reaction, DNA from the wild-type allele generated a MboII restriction site, which is an amplification created restriction site. This did not occur, however, with DNA fragments from the mutant allele. Therefore, determination of the heterozygous genotype, the coexistence of wild-type and mutant alleles, was easily possible. Analysis of the MboII restriction digests of the PCR products was completed in less than 20 min, showing two peaks corresponding to fragments of 125 (cleaved) and 135 (uncleaved) base pairs (bp), respectively. On the other hand, determination of the homozygous genotype, wild-type or mutant, was difficult in one electrophoresis run. The CGE of the MboII restriction digests gave a single peak and the identification, cleaved or uncleaved, was difficult under our experimental conditions. However, the addition of aliquots of the PCR reaction mixture to the restriction digests, followed by re-electrophoresis, allowed successful diagnosis, yielding two peaks (cleaved and uncleaved) for the wild-type and one peak (uncleaved) for the mutant allele. This study demonstrated that CGE offers a high-speed, high-resolution analytical tool for determining genetic types, as compared

with the conventional slab gel methodologies.

Verheyden, G., G. Volckaert, et al. (2000). "Expression of chymotrypsin(ogen) in the thioredoxin reductase deficient mutant strain of Escherichia coli AD494(DE3) and purification via a fusion product with a hexahistidine-tail." Journal of Chromatography B: Biomedical Sciences and Applications **737**(1-2): 213.

<http://www.sciencedirect.com/science/article/B6TG9-3Y9G71W-VI2/c4c9d747dfd4255b783a1b02d9a9e77b>

A reliable protocol was designed for fast expression and purification of recombinant chymotrypsin(ogen). The zymogen was overexpressed in soluble form as a (His)6-fusion construct in the cytoplasm of the thioredoxin reductase deficient Escherichia coli strain AD494(DE3). This allowed purification of chymotrypsinogen in a highly selective affinity chromatography capture step using a Ni-NTA column. After activation with enterokinase, the enzymatically active chymotrypsin was purified in a polishing step using a modified soybean trypsin inhibitor agarose column. This expression system and the use of affinity chromatography for capture and polishing, offers an easier and faster route to recombinant chymotrypsin(ogen) than the previously described use of Saccharomyces cerevisiae.

Wei, W. and E. S. Yeung (2000). "Improvements in DNA sequencing by capillary electrophoresis at elevated temperature using poly(ethylene oxide) as a sieving matrix." Journal of Chromatography B: Biomedical Sciences and Applications **745**(1): 221.

<http://www.sciencedirect.com/science/article/B6TG9-40WDPWN-M/2/b69c080b31109ce5a637857961160f0d>

DNA sequencing in poly(ethylene oxide) (PEO) matrix by capillary electrophoresis was demonstrated at high temperature. The optimal separation temperature is around 40[deg]C. The effects of polymer concentration and types of buffers on the separation performance were investigated. A new buffer system consisting of Tris-Taps-His-EDTA works well with PEO. High-speed separation and good resolution can be fulfilled by using a single-MW PEO polymer. It offers similar separation performance as before for the small DNA fragments, but better performance for large DNA fragments.

Journal of Clinical Forensic Medicine (1)

Chattopadhyay, P. and S. Guha "RAPD & FINS (mitochondrial 16s rRNA gene sequence) in analysis of food contamination: detection of food poisoning by Lizard." Journal of Clinical Forensic Medicine In Press, Corrected Proof <http://www.sciencedirect.com/science/article/B6WHN-4DJ49HS-1/2/ac01b2bcf45336052a58c9df386af167>

In poisoning, detection of the nature of causative agent is important for management of trauma and forensic investigation. Most of the methods in clinical toxicology are developed for detection of toxins and poisons. A random amplified polymorphic DNA (RAPD)-based method has been

described for detection of species of animal from its morphologically unrecognizable fragments, recovered from food substances, consumption of which caused even death. Pre-mixed RAPD reaction beads and six RAPD primers were used in polymerase chain reaction analysis. Among six RAPD primers used, any one of them was sufficient in resolving this practical forensic situation. To enhance the probability values for matching in the present study of fixing identity of an animal, six set of market available RAPD primers were used. This is the first report of a forensic application of RAPD DNA typing in identification of charred skeleton remnants of Lizard species in food material. Furthermore unique amplicons were generated for different reptilian species, which can be used as species specific markers for species identification in forensic situation, however, no variations among individuals of same species were observed.

Al-Soud, W. A. and P. Radstrom (2001). "Purification and Characterization of PCR-Inhibitory Components in Blood Cells." Journal of Clinical Microbiology **39**(2): 485.

<http://jcm.asm.org/cgi/content/abstract/39/2/485>

In a recent study, immunoglobulin G in human plasma was identified as a major inhibitor of diagnostic PCR (W. Abu Al-Soud, L. J. Jonsson, and P. Radstrom. J. Clin. Microbiol. 38:345-350, 2000). In this study, two major PCR inhibitors in human blood cells were purified using size exclusion and anion-exchange chromatographic procedures. Based on N-terminal amino acid sequencing and electrophoretic analysis of the purified polypeptides, hemoglobin and lactoferrin were identified as PCR-inhibitor components in erythrocytes and leukocytes, respectively. When different concentrations of hemoglobin or lactoferrin were added to PCR mixtures of 25 {micro}l containing 10 different thermostable DNA polymerases and 1 ng of *Listeria monocytogenes* DNA as template DNA, AmpliTaq Gold, Pwo, and Ulta were inhibited in the presence of [≤]1.3 {micro}g of hemoglobin and [≤]25 ng of lactoferrin, while rTth and Tli were found to resist inhibition of at least 100 {micro}g of hemoglobin. In addition, the quantitative effects of seven low-molecular-mass inhibitors, present in blood samples or degradation products of hemoglobin, on real-time DNA synthesis of rTth using the LightCycler Instrument were investigated. A reaction system based on a single-stranded poly(dA) template with an oligo(dT) primer annealed to the 3' end was used. It was found that the addition of 0.25 to 0.1 mg of bile per ml, 2.5 mM CaCl₂, 0.25 mM EDTA, 5 {micro}M FeCl₃, and 0.01 IU of heparin per ml reduced the fluorescence to approximately 76, 70, 46, 17, and 51%, respectively. Finally, the effects of nine amplification facilitators were studied in the presence of hemoglobin and lactoferrin. Bovine serum albumin (BSA) was the most efficient amplification facilitator, so that the addition of 0.4% (wt/vol) BSA allowed AmpliTaq Gold to amplify DNA in the presence of 20 instead of 1 {micro}g of hemoglobin and 500 instead of 5 ng of lactoferrin. Including 0.02% (wt/vol) gp32, a single-stranded-DNA binding protein, in the reaction mixture of AmpliTaq Gold was also found to reduce the inhibitory effects of hemoglobin and lactoferrin.

Hendolin, P. H., L. Paulin, et al. (2000). "Clinically Applicable Multiplex PCR for Four Middle Ear Pathogens." Journal of Clinical Microbiology **38**(1): 125.

<http://jcm.asm.org/cgi/content/abstract/38/1/125>

The multiplex PCR method for the detection of *Alloiococcus otitidis*, *Haemophilus influenzae*, *Moraxella catarrhalis*, and *Streptococcus pneumoniae* (P. H. Hendolin, A. Markkanen, J. Ylikoski, and J. J. Wahlfors, *J. Clin. Microbiol.* 35:2854-2858, 1997) in middle ear effusions (MEEs) was modified to be better suited for clinical use. To detect false-negative results, an internal amplification was added to the reaction, and to prevent carryover contamination, the dUTP-uracil-N-glycosidase system was incorporated into the procedure. Labor was minimized by using the heat-activatable AmpliTaq Gold polymerase in order to circumvent manual hot start and by detecting the amplification products on an automated sequencer. The performance of the improved protocol was verified with MEEs from patients with otitis media with effusion. In addition, a ligase detection reaction (LDR) was developed for confirmation of the PCR products. The modifications increased the reliability of the protocol and the hands-off time significantly. However, when two DNA extraction protocols were compared, gram-negative bacteria were detected more often in phenol-treated MEEs (94 versus 46%; $P < 0.001$), and gram-positive bacteria were detected more often in MEEs dissolved in sodium dodecyl sulfate-NaOH-chaotropic salt (83 versus 27%; $P < 0.001$). The LDR was found to be 100% specific. In all, the results demonstrate the feasibility of the rapid (7-h) multiplex PCR method for routine laboratory use.

Journal of Clinical Virology (52)

Aalto, S. M., E. Juvonen, et al. (2003). "Lymphoproliferative disease after allogeneic stem cell transplantation--pre-emptive diagnosis by quantification of Epstein-Barr virus DNA in serum." *Journal of Clinical Virology* **28**(3): 275.

<http://www.sciencedirect.com/science/article/B6VJV-481N3TM-1/2/548944775c9856ebe2d62b6d2f001967>

Background: Lymphoproliferative disease (PTLD) is a life-threatening complication of organ transplantation. In matched, allogeneic, non-T-cell-depleted stem-cell transplantations (SCT) the disease develops early but has been thought to be rare. **Objectives:** We determined by strict histopathological criteria the incidence of fatal Epstein-Barr-virus (EBV)--related PTLD in a large number of SCT, and assessed the diagnostic value of a real-time quantitative polymerase chain reaction (qPCR) for EBV-DNA in serum specimens. **Study design:** Of the 257 SCT performed in Helsinki during 1994-1999, 132 (51%) recipients were alive and 125 (49%) had succumbed by June 2001. The necropsies were analyzed for EBV-related PTLD as evidenced by disseminated lymphocytic infiltrates labeled histochemically for antigens and RNA (EBER 1 and 2) detectable by in situ technology. From a subset of the PTLD cases (N=12) and a series of corresponding stem-cell recipient controls (N=36), consecutive samples of serum (N=103 and 364, respectively) were studied by qPCR for EBV-DNA, and the clinical data were reviewed. **Results:** The post-mortem analysis revealed 18 cases of PTLD (14% of the deceased), all of whom had received intensive immunosuppressive treatment including anti-thymocyte globulin for treatment or prophylaxis of graft versus host disease (GVHD). By using qPCR all the PTLD patients became EBV-DNA positive, in progressively rising copy numbers. EBV-DNA was first detectable 70 (median; range 24-154) days after SCT or 23 (4-86) days before death; i.e. earlier than the symptoms which appeared 15 (2-85) days before death. Among the SCT controls, EBV-DNA occurred sporadically (in only 3.9% sera). **Conclusions:** qPCR for EBV-DNA in serum is a highly sensitive (100%) and specific (96%) diagnostic approach. Intensely immunosuppressed stem-cell recipients are at a great risk of developing PTLD, and should be carefully monitored for EBV-DNA, for pre-emptive treatment of this life-threatening disorder.

Abe, K., E. Hayakawa, et al. (2004). "Molecular epidemiology of hepatitis B, C, D and E viruses among children in Moscow, Russia." Journal of Clinical Virology **30**(1): 57.

<http://www.sciencedirect.com/science/article/B6VJV-4B0WSYR-1/2/c6b387c19e3e472a4620c9f358329d21>

Background: It is known that the prevalence of HBV and HCV infections vary according to geographical areas. However, in Russia, an adequate level of information on the molecular epidemiology of hepatitis viruses has not been available so far. Objectives: To investigate the characterization of various hepatitis viruses in Russia, we conducted molecular-based epidemiological survey of hepatitis viruses including hepatitis B virus (HBV), hepatitis C virus (HCV), hepatitis D virus (HDV) and hepatitis E virus (HEV) among children in Moscow, Russia. Study design: The study population of 374 subjects (ranging in age from 1 to 14 years old) consisted of 195 patients with liver diseases and 179 patients without liver diseases. Viral DNA/RNA was determined by nested PCR. Genotyping of HBV and HCV were examined by PCR using type-specific primers. Anti-HEV antibody was assayed by ELISA. Results: The infection rate of each virus among patients with liver diseases including acute hepatitis, chronic hepatitis or cirrhosis was 65.6% for HBV and 15.9% for HCV. In contrast, among non-liver disease patients, the infection rates were 14.4% for HBV and 0.6% for HCV, respectively. The most common viral genotypes were type D (85%) of HBV and type 1b (79.3%) of HCV. HDV RNA was detected in 7 of 149 (4.7%) HBV DNA-positive children tested. Moreover, testing for HEV among 341 subjects resulted in the detection of anti-HEV IgG in 62 cases (18.2%). Conclusions: Our results suggest that HBV infection is widespread in Moscow and have led to a high incidence of acute and chronic liver diseases among children in this region.

Aho, J., J. R. Kornegay, et al. (2004). "Evaluation of a convenient enzyme immunoassay to assess the quality of genital specimens submitted for the detection of human papillomavirus DNA by consensus PCR." Journal of Clinical Virology **29**(2): 127.

<http://www.sciencedirect.com/science/article/B6VJV-4BH98CW-3/2/c44d338febd6971d7dc63bbcb554e269>

Background: In the PGMY-line blot assay, a human [beta]-globin fragment is co-amplified with human papillomavirus (HPV) DNA, and both analytes are detected by hybridization with probes fixed on a strip in a linear array. The [beta]-globin DIG-MWP test also detects [beta]-globin amplicons, but in a microtiter plate-based enzyme immunoassay format. Although the PGMY-line blot assay detected 50 cells per test, the [beta]-globin DIG-MWP test generated a signal above the detection cut-off with five cells per test. Objective: The performance of the [beta]-globin DIG-MWP assay to detect [beta]-globin DNA was assessed. Study design: The [beta]-globin DIG-MWP assay was compared to a standard [beta]-globin PCR and to the PGMY-line blot strips on 401 genital specimens. Overall, the three [beta]-globin assays were compared on 325 undiluted lysates, 14 diluted lysates and DNA extracted from 62 lysate samples. Results: Concordance between the PGMY-line blot and the standard [beta]-globin assay reached 99.5% (399 of 401 results), for a kappa value of 0.95. Concordant results were also obtained between the [beta]-globin DIG-MWP assay and PGMY-line blot assay for 387 (96.5%) of 401 test results, for a kappa value of 0.57. Discordant results were due to the increased sensitivity of the DIG-MWP assay. Using a cut-off for positivity at 1.500 optical density (OD) units for [beta]-globin DIG-MWP, concordance improved to 100% (401 of 401 results, kappa at 1.00). Conclusion: The [beta]-globin DIG-MWP assay was adequate to screen for sample adequacy for HPV analysis in genital specimens.

Alhababi, F., T. A. Sallam, et al. (2003). "The significance of 'anti-HBc only' in the clinical virology

laboratory." Journal of Clinical Virology **27**(2): 162.

<http://www.sciencedirect.com/science/article/B6VJV-47GHSK0-2/2/227591233d6afc4b0a10cc4e54d949ad>

Background: Isolated detection of hepatitis B core antibody (anti-HBc) in the absence of surface antigen (HBsAg) or antibody (anti-HBs) has been reported, particularly among individuals infected with human immunodeficiency virus (HIV) and hepatitis C virus (HCV). The significance of this phenomenon is unknown and it is unclear whether all individuals with such serological pattern need further molecular investigations. **Objectives:** To determine the prevalence of 'anti-HBc only' in samples referred to a clinical virology laboratory and to evaluate its significance and possible mechanisms. **Study design:** Samples identified as anti-HBc positive (389/4359, 8.9%) during an 11-month period were investigated for HBsAg, anti-HBs, anti-HCV and anti-HIV. 'Anti-HBc only' samples were tested for HBV DNA using a nested qualitative PCR. Viral loads were measured in samples with detectable HBV DNA and the DNA sequences were analysed. **Results:** Of 379 samples with detectable anti-HBc, 155 (40.9%) were 'anti-HBc only'. HBV DNA was detected in 6/151 (4%), all of which had a viral load. **Conclusions:** 'Anti-HBc only' is a common phenomenon in the clinical virology laboratory but only a small proportion of samples had detectable HBV DNA. The presence of HBsAg mutants with possible false negative HBsAg test result is of concern. Samples with 'anti-HBc only' could be used to monitor the emergence of these mutants.

Behzad-Behbahani, A., P. E. Klapper, et al. (2004). "Detection of BK virus and JC virus DNA in urine samples from immunocompromised (HIV-infected) and immunocompetent (HIV-non-infected) patients using polymerase chain reaction and microplate hybridisation." Journal of Clinical Virology **29**(4): 224.

<http://www.sciencedirect.com/science/article/B6VJV-49569PK-1/2/b636d3c894f1b48d112df279e87ccdb9>

Background: The majority of the human population is infected with two human polyomaviruses BK virus (BKV) and JC virus (JCV) during childhood. After initial infection both viruses persist within renal system. Reactivation of both viruses may be linked with immunodeficiency or immunosuppressive therapy. **Objective:** To evaluate the relationship between immunodeficiency and viruria, prevalence of BK and JC viruria over time was investigated in a cohort of HIV seropositive individuals at different stages of disease. The excretion in this group was compared with virus excretion in their HIV seronegative partners and in an unselected cohort of patients attending a Genito-Urinary Medicine (GUM) clinic. **Study design:** The excretion of BKV and JCV DNA in multiple urine samples from HIV-infected patients at different stages of disease and their HIV-negative partners, and in single samples from a cohort of patients at a GUM clinic was investigated. A microplate hybridisation method was developed to increase both the sensitivity and specificity of detection of the PCR product. The method was also applied to estimate the DNA copy numbers of BKV and JCV in urine samples. **Results:** Within the HIV group, the level of immunosuppression (CD4+ category) was not associated with JCV viruria. By contrast, there was a modest correlation between immunodeficiency as indicated by a decline in CD4+ count and BKV viruria. Shedding of both BKV and JCV DNA together in urine samples of HIV-infected patients was much higher than in control groups ($P=0.02$), indicating that HIV infection may associate with polyomavirus reactivation. The incidence of flu-like syndrome was much higher in HIV-infected asymptomatic individuals than acquired immunodeficiency syndrome (AIDS)-related complex (ARC)/AIDS patients. In general, the concentration of BKV DNA viruria (DNA copy number) was dependent to CD4+ counts ($P=0.008$) while concentration of JCV DNA was independent to CD4+ cell count ($P=0.54$). The prevalence of BKV and JCV DNA in patients who were infected with *C. trachomatis* was 9/50 (18%) and 11/50 (22%), respectively. BKV and JCV DNA was detected in 3/19 (15%) and 2/19 (10%) of patients who were infected with *N. gonorrhoea*. Results suggested that persons infected with *C. trachomatis* were more likely to

show BKV and JCV viruria. Conclusion: These results confirm that shedding of BK and JC viruses in urine is not exclusively found in immunosuppression, it may also occur in healthy individuals. The frequency of virus excretion is however, apparently increased in HIV-infected patients, although no firm statistical difference could be established. One of the interesting aspects of these findings was the relatively high incidence of BKV and JCV viruria in both control groups, i.e. HIV-negative partners of HIV-infected patients and patients attending a GUM clinic.

Bettinger, D., C. Mougin, et al. (1999). "Direct in situ reverse transcriptase-linked polymerase chain reaction with biotinylated primers for the detection of hepatitis C virus RNA in liver biopsies." Journal of Clinical Virology **12**(3): 233.

<http://www.sciencedirect.com/science/article/B6VJV-3WHKSV2-6/2/a7d035831900f1fbaf831a7f78205515>

To assess the presence and the cellular distribution of hepatitis C virus (HCV) RNA in the liver of 11 patients with confirmed HCV infection, a direct in situ reverse transcriptase-linked polymerase chain reaction (RT-PCR) method was performed on formalin-fixed and paraffin-embedded biopsies. The oligonucleotide primers used were specific to the 5' non coding region. An unlabelled downstream oligonucleotide served as a primer for reverse transcription as well as PCR. The upstream oligonucleotide serving as a primer for PCR was biotinylated, allowing a direct enzymatic detection of PCR products. HCV infected cells revealed cytoplasmic staining mainly concentrated towards the interface of the nucleus and cytoplasm. Most of the stained cells were hepatocytes and sometimes Kupffer cells. The results were compared with those obtained by RT-PCR of RNA extracted from the corresponding tissue block. Extracted HCV RNA could be detected in liver tissues of nine out of 11 (82%) infected patients. The detection rate using in situ RT-PCR was 7/11 (63%). The use of labelled primers improved specificity of direct in situ methods, by preventing non-specific incorporation of labelled dNTPs into fragmented DNA. Further studies are however required in order to increase detection sensitivity of HCV infection by in situ molecular methods.

Bogh, M., R. Machuca, et al. (2001). "Subtype-specific problems with qualitative Amplicor HIV-1 DNA PCR test." Journal of Clinical Virology **20**(3): 149.

<http://www.sciencedirect.com/science/article/B6VJV-428FK8V-B/2/4ca8226839097a126d7f83b338fa219c>

Background: commercial HIV-1 qualitative DNA PCR tests have the potential to detect virus in patients in whom antibody tests may be ineffective, such as patients with primary HIV infection and infants born to HIV seropositive mothers. However, the genetic diversity of HIV-1 raises concern about the ability of the PCR tests to detect all current subtypes. Objectives: to assess the sensitivity of the Amplicor HIV-1 test on 126 whole-blood samples representing seven different subtypes and to investigate the sensitivity when the standard assay was modified by including the primer pair SK145 and SKCC1B. Results: of the 126 HIV-1 infected persons, 113 were tested positive and 13 were DNA PCR negative. On the basis of these results, the standard Amplicor HIV-1 test had a sensitivity of 90% in our cohort. In addition, 9% of the positive samples showed a low reactivity but above the cut-off of the assay. The standard assay yielded sensitivities of 100% for subtype B (n=16), D (n=9) and G (n=1), but only 83% for subtype A (n=41), 98% for subtype C (n=43), 79% for subtype E (n=14) and 0% for subtype F (n=2). All samples with low reactivity were non-B subtype. Eight of the DNA PCR negative samples, four subtype A, one C and three E were amplified with the modified Amplicor HIV-1 test with addition of SK145/SKCC1B primers. Using this modified protocol, six samples out of eight became positive. However, two samples (one A and one C) remained DNA PCR negative. Conclusion: this study confirms that

the Amplicor HIV-1 test does not detect all subtypes with equivalent sensitivity and 10% of the samples, tested negative. Thus, it is preferable to add the SK145/SKCC1B primers to the standard test, where infection with non-B subtype is suspected.

Brinkman, J. A., M. Z. Rahmani, et al. (2004). "Optimization of PCR based detection of human papillomavirus DNA from urine specimens." *Journal of Clinical Virology* **29**(4): 230.

<http://www.sciencedirect.com/science/article/B6VJV-497RH9B-1/2/dc95c75967e7fa4e323afe877e6df9d6>

Background: Human papillomavirus (HPV) causes cervical cancer. Current screening requires a yearly pelvic exam and Pap smear. However, these procedures are impractical for screening all women at risk for disease. Urine sampling has been successfully utilized to screen for Chlamydia trachomatis (CT) and Neisseria gonorrhoeae (NG) infections and has been considered for HPV DNA detection by several investigators. However, no study to date has been performed to specifically optimize HPV detection in urine. Objectives: To compare handling and extraction techniques in order to optimize the HPV specific PCR system in urine specimens. Study design: Examination of 10 characteristics that may contribute to PCR inhibition in urine was performed utilizing 10SG multistix. Five different DNA extraction methods were compared in spiked specimens and in 10 clinical specimens. After the optimal extraction technique was identified, concentration of the sample with and without prior dilution was compared to the original protocol. Lastly, specimen handling was compared between immediate processing, refrigerating overnight, or freezing overnight. Results and conclusions: the presence of protein in urine enhanced amplification while nitrites decreased amplification. Of the extraction methods tested, the QIAamp DNA Mini Kit demonstrated the best amplification from urine samples spiked with HPV DNA and clinical specimens. The addition of a dilution step and a concentration step before applying the Qiagen protocol further increased amplification of [beta]-globin (from 50 to 63%) and the HPV L1 gene (from 13 to 33%). Lastly, refrigerating the specimens at 4 [deg]C overnight appears to produce better amplification (62% [beta]-globin and 17% HPV positive) than either immediate processing (46% [beta]-globin and 13% HPV+) or freezing the specimen for 24 h prior to processing (46% [beta]-globin and 10% HPV+). In these studies, amplification was low despite optimization. Additional improvements are required prior to clinical application of a urine-based HPV DNA detection system.

Castelain, S., V. Descamps, et al. (2004). "TaqMan amplification system with an internal positive control for HCV RNA quantitation." *Journal of Clinical Virology* **31**(3): 227.

<http://www.sciencedirect.com/science/article/B6VJV-4C9HS4H-1/2/f0938d77c3b23f73a154830dc6101c58>

Background: Quantitation of hepatitis C virus (HCV) RNA has become an essential tool for monitoring antiviral therapies in chronically infected patients. Different quantitative HCV RNA assays have been reported, mainly using techniques based on signal amplification with branched DNA (bDNA) technology or target sequence amplification by reverse-transcription PCR method (RT-PCR). Objectives and study design: An RT-PCR assay using TaqMan (fluorescence-based real-time PCR) and minor groove binding (MGB) probes was designed for the quantitative determination of HCV RNA in the clinical samples. Calculation of the concentration of HCV RNA was based on an external standard curve in the presence of an internal positive control (IPC). Results: The assay detected 550 international units (IU)/mL with >95% probability of a positive result, with a linear range extending up to 10,000,000 IU/mL. The test exhibited good reproducibility with intra-assay and inter-assay coefficients of variation (CV) of 1.6% and 3.2%, respectively. All the major HCV genotypes were quantified with equivalent efficiency and

accuracy. HCV genotypes 5 and 6 have also been amplified but too few samples have been tested. The performance of this new assay for quantitation of HCV viremia was evaluated with 213 anti-HCV positive sera, 120 of which corresponded to 30 patients sampled during the therapy. We used the Amplicor HCV Monitor assay (Roche Diagnostics, France) and the bDNA VERSANT HCV RNA assay (Bayer Diagnostics, France) to analyze 173 and 40 samples, respectively. The assay described here was significantly correlated with both commercial assays ($R^2=0.9535$, $PR^2=0.8508$, P -Conclusion: The present study illustrated the high reproducibility and reliability of our TaqMan HCV assay. Moreover, the monitoring of viral decline with our assay gave the same results as those obtained with the commercial assays indicating that this new technique provides an attractive approach for measuring HCV viral load.

Comanor, L., C. Elkin, et al. (2003). "Successful HCV genotyping of previously failed and low viral load specimens using an HCV RNA qualitative assay based on transcription-mediated amplification in conjunction with the line probe assay." Journal of Clinical Virology **28**(1): 14.

<http://www.sciencedirect.com/science/article/B6VJV-47CYDC0-2/2/92e5183f511803a8068fe5bd0d1415ff>

Background: Hepatitis C virus (HCV) genotyping is a critical part of the diagnostic work-up for chronic hepatitis C. The VERSANT(R) HCV line probe assay (LiPA) marketed by Bayer Corporation requires PCR-derived amplicons for genotyping usually obtained from commercial assays, including Amplicor(R) HCV 2.0 (Amplicor 2.0), Amplicor HCV Monitor(R) 2.0, or SuperQuant(R). Occasionally, PCR-based methods in conjunction with LiPA fail to give a genotyping result. Although most genotyping failures occur among low viral load specimens, some occur in specimens with relatively high viral loads. The Bayer HCV RNA Qualitative assay (HCV TMA), with a limit of detection of approximately 5-10 IU/ml, is more sensitive than other commercial assays. Objectives: An HCV genotyping protocol using HCV TMA linked with LiPA (TMA-LiPA) was developed and tested for ability to genotype samples that had previously failed genotyping by PCR-based methods in conjunction with LiPA. Study design: Clinical specimens were obtained from eight independent laboratories in Canada and the US and tested with TMA-LiPA at the Bayer Reference Testing Laboratory. Specimens included those that failed to produce a genotype result when a PCR-based assay was used in conjunction with LiPA and specimens for which genotyping was not attempted because the viral load was below the validated cut-off determined in the laboratory of origin. Results and conclusions: TMA-LiPA successfully genotyped 68 of 75 (90.7%) specimens that had failed genotyping by PCR-based methods used in conjunction with LiPA and 36 of 40 (90.0%) specimens that were rejected for genotyping due to low viral load. Moreover, TMA-LiPA assigned subtype for 79 of 107 (73.8%) specimens. Our TMA-LiPA results reflected the distribution of HCV genotypes found in North America, and were 100% concordant with those of Amplicor 2.0 in conjunction with LiPA for control specimens genotyped by both assays. TMA-LiPA may prove useful both in optimizing LiPA performance and genotyping patient specimens.

Drosten, C., T. Nippraschk, et al. (2004). "Prevalence of hepatitis B virus DNA in anti-HBc-positive/HBsAg-negative sera correlates with HCV but not HIV serostatus." Journal of Clinical Virology **29**(1): 59.

<http://www.sciencedirect.com/science/article/B6VJV-48NJ8FR-1/2/9f53c5175f130b046a8377e65674cf25>

Background: Hepatitis B virus (HBV) DNA often remains detectable in serum despite clinical recovery and loss of HBsAg. Objective: To study whether coinfection with HIV and HCV influence the chance of detecting HBV DNA in sera with markers of past hepatitis B. Study design and

results: The test panel included 160 anti-HBc-positive/HBsAg-negative sera collected in the diagnostic setting. The following parameters were determined in the sera: anti-HIV (32% positive), anti-HCV (34% positive), HCV RNA (18% positive), and anti-HBs (37% positive). A highly sensitive PCR (90%-detection limit 100 copies/ml) amplifying the terminal protein (TP) region of HBV was established and HBV DNA was detected in 12.5% of the samples. In 70% of these samples, the HBV DNA concentration was below 500 copies/ml as measured by real-time PCR in the S gene. Logistic regression analysis revealed that the chance of detecting HBV DNA was increased by a positive HCV serostatus (odds ratio 5.0, 95%-CI 1.6-15.7), whereas HIV coinfection (odds ratio 2.0, 95%-CI 0.7-5.8), anti-HBs (odds ratio 0.9, 95%-CI 0.3-2.6), and HCV RNA status (odds ratio 0.4, 95%-CI 0.1-1.7) had no statistically significant influence. In contrast, the chance of detecting HCV RNA in the subgroup of anti-HCV-positive sera was increased by HIV coinfection (odds ratio 4.5, 95%-CI 1.2-17.4). Sequencing of the TP PCR products revealed neither a specific phylogenetic origin of the circulating HBV DNA nor clustering of uncommon mutations in the TP region. Conclusions: The prevalence of HBV DNA in serum of anti-HBc-positive/HBsAg-negative subjects correlates with HCV rather than HIV serostatus.

Feucht, H.-H., B. Zollner, et al. (1999). "High rate of chronicity in HCV infection determined by antibody confirmatory assay and PCR in 4110 patients during long-term follow-up." Journal of Clinical Virology **13**(1-2): 43.

<http://www.sciencedirect.com/science/article/B6VJV-3WMK61W-6/2/3115c987578d07d017c1adb25e9dd118>

Background: It is still unclear how many patients with hepatitis C virus (HCV) antibodies have viremia and hence are infectious. Objectives: To determine the chronicity of HCV infection by correlation of HCV antibodies with presence of viremia in long-term follow-up. Study design: In a longitudinal study sera of 4110 patients were analyzed with second generation HCV-enzyme immunoassay (EIA) and polymerase chain reaction (PCR). Only those patients were included in this study in whom sequential serum samples over a period of 2 years were available. To avoid preanalytical and analytical failures, we used a transport solution to prevent RNA degradation and a four-antigen recombinant immunoblot assay, established in our laboratory, for confirmation of antibody reactivity. Results: Of 2815 patients with confirmed HCV antibodies 2784 (98.9%) were also positive in HCV-PCR assay. False reactive EIA results were detected in 177 (13.7%) individuals as shown by confirmatory assay and PCR. Only one patient (0.04%) spontaneously lost detectable HCV viremia and subsequently HCV-specific antibodies. Conclusions: Our study clearly demonstrates that presence of confirmed HCV-specific antibodies correlates significantly (98.9%; $P < 0.001$) with HCV viremia, and that spontaneous loss of viremia is a very rare event in HCV infection. We also found that elimination of HCV infection is not sufficiently predicted by the loss of detectable viremia in PCR, but can be concluded from the disappearance of virus-specific antibodies.

Gahan, M. E., F. Miller, et al. (2001). "Quantification of mitochondrial DNA in peripheral blood mononuclear cells and subcutaneous fat using real-time polymerase chain reaction." Journal of Clinical Virology **22**(3): 241.

<http://www.sciencedirect.com/science/article/B6VJV-43YR0F4-4/2/c1710dcc7bccf794d09bb5108f348499>

Background: With decreased rates of HIV mortality and disease progression attributable to treatment with nucleoside analogue reverse transcriptase inhibitors (NRTIs), attention has now become focused on the toxicities of these forms of treatment. It is believed NRTIs cause a decrease in mitochondrial DNA (mtDNA) synthesis due to their inhibition of DNA polymerase

gamma. This hypothesis is supported by in vitro data from muscle biopsies and human lymphoblastic cell lines. The resulting mitochondrial toxicity is thought to manifest itself in a variety of clinical symptoms including fatigue, fat wasting and peripheral neuropathy. A non-invasive test of mitochondrial toxicity is needed to assess toxicity and optimise HIV treatment strategies. Peripheral blood mononuclear cells (PBMC) and subcutaneous fat could be ideal and accessible sources of mtDNA for examining toxicity. Objectives: The objectives of this study were (a) to develop an assay to quantify the mtDNA copy number of PBMC and obtain reproducible results and (b) to establish the utility of subcutaneous fat as a source of mtDNA for quantification. Study Design: PBMC were isolated from blood by centrifugation over Ficoll-Paque(R) and subcutaneous fat was obtained from two 3 mm punch skin biopsies. Following DNA extraction, the mtDNA copy number in each sample was quantified by real-time polymerase chain reaction (PCR). Results: The real-time PCR assay was found to generate consistent and reproducible results with replicates of samples undertaken within the same run, and in two or more different runs, having a mean coefficient of variation of 11.3 and 17.2%, respectively. PBMC and subcutaneous fat contained 409+/-148 and 2042+/-391 copies of mtDNA per cell, respectively. Conclusions: From the work carried out it can be concluded that firstly, the real-time PCR assay generates consistent and reproducible results, and secondly that mtDNA can be extracted and quantified from PBMC and subcutaneous fat.

Gaidano, G., D. Capello, et al. (2000). "Molecular characterization of HHV-8 positive primary effusion lymphoma reveals pathogenetic and histogenetic features of the disease." Journal of Clinical Virology **16**(3): 215.

<http://www.sciencedirect.com/science/article/B6VJV-3YWXPNR-6/2/aca85e33d15e7a3314566d8bd2eac048>

Background: Primary effusion lymphoma (PEL) associates with HHV-8 infection, preferentially develops in immunodeficient patients and grows in the serous body cavities. PEL derives from post-germinal center, pre-terminally differentiated B-cells. The pathogenesis of PEL is unclear and the sole identified genetic lesions are human herpesvirus type-8 (HHV-8) infection in all cases and EBV infection in 70% of cases. Epstein-Barr virus (EBV) infection in PEL displays a latency I phenotype. Objectives: To clarify the pathogenesis and histogenesis of PEL by investigating (1) the lymphoma karyotype; (2) the expression status of the Met tyrosine kinase receptor and of its ligand hepatocyte growth factor (HGF); (3) the molecular profile of EBV, with particular focus on mutations of EBNA-1 genes, which are thought to affect viral tumorigenicity in EBV-infected neoplasms displaying the latency I phenotype. Study design: Twenty-four PEL (nine cell lines and 15 primary specimens) formed the basis of the study. Karyotypes were investigated by conventional cytogenetics and fluorescent in situ hybridization (FISH) in selected cases. The expression status of Met and HGF was defined by multiple techniques, including RT-PCR, FACS analysis, immunocytochemistry, Western blot studies and ELISA. The molecular profile of EBNA-1 genes of EBV were investigated by DNA direct sequencing. Results: Trisomy 7, trisomy 12 and breaks at 1q21-q25 are recurrently associated with PEL. PEL consistently co-express Met and HGF both at the mRNA and protein level. Among aggressive B-cell lymphomas, Met/HGF co-expression appears to be relatively specific for PEL. The EBNA-1 gene of EBV displays a high degree of genetic heterogeneity in PEL, with no preferential association with one specific variant. Conclusions: PEL associates with recurrent chromosomal alterations, suggesting that viral infection is not sufficient for tumor development and that lesions of cellular genes may be required. The expression of Met/HGF by PEL cells may bear implications for the lymphoma proliferation and growth pattern, since Met/HGF interactions influence cell mitogenesis and motogenesis. EBV infection in PEL displays a latency I phenotype and fails to associate with specific EBNA-1 variants, suggesting that the role of EBV in PEL is not mediated by the major transforming pathways currently known in EBV positive lymphomas.

Gibellini, D., P. Monari, et al. (2003). "A rapid hemi-nested PCR for HTLV-I detection." Journal of Clinical Virology **28**(3): 341.

<http://www.sciencedirect.com/science/article/B6VJV-49FGX81-1/2/92ed4730be53788e5815bf9904d64250>

A hemi-nested PCR approach was adopted to detect HTLV-1 infection in clinical samples of peripheral blood mononuclear cells (PBMCs) from subjects with positive or indeterminate serological results. Our results showed that the hemi-nested PCR quickly solved the diagnostic query, detecting the presence of proviral HTLV-1 DNA in two of the 252 patients with inconclusive serological results. The main advantage of this method are the typology of DNA extraction, allowing a consistent DNA recovery without amplification problems, the rapidity (4-5 hours), the performance of the assay and its comparable or better sensitivity than other HTLV-1 PCR formats.

Giovannelli, L., G. Capra, et al. "Atypical squamous cells of undetermined significance-favour reactive compared to atypical squamous cells of undetermined significance-favour dysplasia: association with cervical intraepithelial lesions and human papillomavirus infection." Journal of Clinical Virology **In Press, Corrected Proof** <http://www.sciencedirect.com/science/article/B6VJV-4FCG29P-1/2/09f10e693d5fefc26923f6ad4a411cd0>

Background and objectives:The current study compared the cervical cytological sub-category "atypical squamous cells of undetermined significance-favour reactive (AFR)", recently recommended to be eliminated by the Bethesda system, to the sub-category "atypical squamous cells of undetermined significance-favour dysplasia (ASC-US)", in terms of prevalence of coexistent squamous intraepithelial lesions of either low-grade (LSIL) or high-grade (HSIL) and rate of human papillomavirus (HPV) infection. **Study design:**One hundred women with AFR and 100 with ASC-US were consecutively included in the study. All patients underwent colposcopy, followed by biopsy when necessary, and were screened for HPV infection by the combined use of Hybrid Capture II (DIGENE) and PCR with MY09/11 primers, the latter followed by direct sequencing of the amplifications products for HPV genotyping. **Results:**LSIL were detected in 5.6% of AFR and 18.5% of ASC-US ($p = 0.00812$), HSIL only in 4.3% of ASC-US. HPV infection was diagnosed in 11.2% of AFR and 38.0% of ASC-US ($p = 0.00003$); high-risk HPV types (namely, HPV-16, -18, -31, -66, -67 and -70) were found in 6.7% of AFR and 22.8% of ASC-US ($p = 0.00239$). Evidence of HPV infection in absence of SIL was proven in 7.1% of AFR and in 22.5% of ASC-US ($p = 0.00622$). **Conclusion:**The association of AFR with SIL and high-risk HPV infection is low but not inexistent. Thus, to avoid the risk of leaving some high-risk AFR patients untreated or without follow-up, it could be proposed to keep AFR as a cytological category and to triage it by HPV testing, similarly to what has been already recommended for ASC-US.

Halwachs-Baumann, G., M. Wilders-Truschnig, et al. (2001). "Cytomegalovirus diagnosis in renal and bone marrow transplant recipients: the impact of molecular assays." Journal of Clinical Virology **20**(1-2): 49.

<http://www.sciencedirect.com/science/article/B6VJV-423JBCT-8/2/c3af3a6c3906aa4cbdca8d9c6cd01125>

Background: Cytomegalovirus (CMV) infections are a major threat in transplant recipients. In recent years, new assays for routine CMV diagnosis, based on molecular techniques, have become available. **Objective:** The impact of molecular assays for CMV diagnosis in transplant recipient was evaluated. **Study design:** A total of 51 transplant recipients were screened for CMV

infection. Serological (AxSYM CMV IgG and recombinant CMV IgM assays), antigenemia, CMV DNA (qualitative in house PCR and the quantitative COBAS AMPLICOR CMV MONITOR Test), and CMV mRNA (NucliSens CMV pp67 Test) tests were compared. Results: In 11/20 bone marrow transplant (BMT) recipients and 10/31 renal transplant (RTX) recipients there was no evidence of active CMV infection. Ten RTX recipients and one BMT recipient were antigenemia positive, 21 RTX and seven BMT recipients were PCR positive (qualitative CMV PCR). There were more BMT recipients CMV DNA positive in serum (7/21) than antigenemia positive (1/21). CMV mRNA was found positive in two BMT recipients (one case with no other evidence of CMV infection, the other one CMV DNA positive and antigenemia negative). The only antigenemia positive BMT recipient was found negative for CMV mRNA, but positive in all other tests. Eight RTX recipients were found positive for CMV mRNA. Six of them were also antigenemia positive and five of those were also found positive for CMV IgM. One CMV mRNA positive RTX recipient was CMV IgM positive but antigenemia negative and the other one CMV mRNA positive RTX recipient was found negative in all other tests. Two antigenemia positive RTX recipients were found negative for mRNA and CMV IgM. Conclusion: Antigenemia was found to be a good screening test for CMV infection in RTX recipients. In BMT recipients, tests based on molecular techniques appeared to be superior compared to antigenemia.

Helbig, K. J., J. George, et al. (2005). "A novel I-TAC promoter polymorphic variant is functional in the presence of replicating HCV in vitro." *Journal of Clinical Virology* **32**(2): 137.

<http://www.sciencedirect.com/science/article/B6VJV-4DS6BHW-4/2/0141689e165dbbe2b2b777732461391a>

Background: Chemokines are strong candidate genes for outcome of HCV infection. I-TAC is a chemokine known to be involved in the inflammatory process of HCV infection, and its expression is upregulated in chronic hepatitis C (CHC). Objectives: The aim of this study was to investigate genetic variability in the I-TAC promoter and to determine the correlation of these variants with HCV disease progression. Study design: I-TAC genotyping was performed in 60 chronic HCV patients and 60 controls using GeneScan analysis. Functional analysis of the I-TAC promoter was performed with the aid of luciferase reporter constructs transfected into Huh-7 cells or Huh-7 cells harbouring HCV genomic and sub-genomic replicons. Cytokine induced production of I-TAC from whole blood cultures was measured using enzyme-linked immunosorbent assay (ELISA). Results: Sequencing of approximately 1 kb upstream of the I-TAC gene start codon revealed the presence of a novel 5 bp deletion mutant (-599del5) in a number of chronic HCV patients. Analysis of the functional potential of this deletion revealed no transcriptional change in Huh-7 cells transfected with luciferase reporter constructs, and this was confirmed in cytokine stimulated whole blood cultures where similar levels of I-TAC were liberated regardless of -599del5 genotype. Conversely, the -599del5 deletion variant significantly reduced transcriptional activity of the I-TAC promoter in the presence of replicating HCV. The distribution frequency of the allele was found to be significantly increased in a chronically HCV infected population compared to healthy controls. Conclusions: The novel I-TAC -599del5 promoter polymorphism is a functional variant in the presence of replicating HCV. Furthermore, this deletion mutant is significantly increased in a chronic HCV cohort and may predispose to HCV disease susceptibility.

Hoffmann, D., B. Buchberger, et al. (2005). "In vitro synthesis of enzymatically active HIV-1 protease for rapid phenotypic resistance profiling." *Journal of Clinical Virology* **32**(4): 294.

<http://www.sciencedirect.com/science/article/B6VJV-4DJ4W65-1/2/84ba6fb2c7b5b20c71dd1c43532e39a7>

Background: Given the expanding antiretroviral therapy, inexpensive and fast HIV drug resistance assays are urgently needed. In this view, we have developed a novel phenotypic resistance test for HIV-1 protease inhibitors (PIs) based on recombinant expression of patient-derived HIV PR in *Escherichia coli* and subsequent enzymatic testing in a fluorescent readout. Objectives: To facilitate and expedite the test procedure, we have introduced coupled in vitro transcription/translation using a commercially available technology called RTS for producing enzymatically active HIV-1 protease (PR). Study design: We expressed one wild type PR and one highly resistant mutant starting from molecular clones as well as three patient-derived PRs. The amplified PR gene was either ligated into an expression vector or directly used as a template for the in vitro transcription/translation reaction. Enzymatic susceptibility data derived from in vitro expressed PRs were correlated to the respective results from *E. coli* expression and genotypic evaluation. Results: All tested enzymes were obtained in sufficient quantities for complete resistance profiling to five PIs. The PRs required no purification prior to the enzymatic assay. Inhibition constants and enzymatic resistance factors compared well to corresponding data from PRs expressed in parallel in *E. coli*. Enzymatic resistance was in good agreement with the respective PR genotype. Conclusion: The presented in vitro transcription/translation system represents a novel approach for HIV PR expression starting from molecular clones or patient samples. Coupled with the enzyme-kinetic PR assay recently developed in our group it allows to sensitively quantify resistance to PIs. The test system is significantly less laborious and faster than currently available phenotypic drug resistance assays.

Huang, L.-W., S.-L. Chao, et al. (2004). "Multiple HPV genotypes in cervical carcinomas: improved DNA detection and typing in archival tissues." *Journal of Clinical Virology* **29**(4): 271.

<http://www.sciencedirect.com/science/article/B6VJV-49FRF8P-1/2/607178c723e215454028f226ce541269>

Background: Human papillomaviruses (HPV) have been considered to be the necessary and central agents of cervical carcinoma. Objective: The aim of this study was to determine the prevalence and genotypes of HPV in archival cervical carcinomas. Study design: The study included 152 paraffin-embedded, formaldehyde-fixed cervical carcinoma specimens. To improve the detection and typing of HPV in archival tissues, we conducted a comprehensive study in which, polymerase chain reaction (PCR)-based methods using E7 type-specific (TS) and L1 modified general primers (MY11/GP6+ and GP5+/GP6+) were employed. Results: Overall HPV prevalence was 98% in the cervical carcinomas. HPV 16 was detected in 66% of the tumors, HPV 18 in 22%, HPV 31 in 13%, HPV 33 in 9%, and HPV 58 in 9%. Notably, multiple HPV types were present in 44 (28.9%) of the 152 cervical carcinomas. The most common co-infections were HPV types 16/18 (12 cases), followed by HPV types 16/31 (7 cases). Additionally, HPV 18 was more frequent in adenocarcinomas and adenosquamous carcinomas (86%) than in squamous cell carcinomas (15.8%) ($P=0.0002$). Conclusions: The combination of L1 general primers and E7 type-specific primers can be of use in detecting HPV DNA in archival tissues. The present study showed a high frequency of multiple HPV infections in cervical carcinomas. Hence, relevant HPV typing information in cervical carcinoma is very important for further HPV vaccine design and application.

Ilona, L.-F., O. Pia, et al. (2003). "Detection of herpes simplex virus DNA in dried blood spots making a retrospective diagnosis possible." *Journal of Clinical Virology* **26**(1): 39.

<http://www.sciencedirect.com/science/article/B6VJV-45TY876-2/2/9b89f8327158f45f6f1bf3fe27d4d812>

Background: Herpes simplex virus (HSV) infections in neonates are associated with life-

threatening disease. Early diagnosis and treatment with antiviral therapy has decreased the morbidity, mortality and long-term sequelae in surviving children. The aim of the study was to investigate if herpes simplex virus DNA detection in dried blood spots on filter papers (Guthrie cards) sampled for screening of metabolic diseases may contribute to early diagnosis of neonatal HSV infection and enable pre-emptive therapy. Methods: For detection of HSV-1 and -2 DNA, two different DNA extraction methods were evaluated. A minimal essential medium (MEM) extraction method was found superior and was used in combination with detection of HSV-1 and -2 DNA by PCR in dried blood spots from children with verified neonatal HSV infection. Cards from 28 children were included. The onset of illness varied from day 0 to 42 days and was the result of different types of maternal infection (27 cases) and an external source (one case). Results: HSV DNA was detected in seven of the 28 Guthrie cards, two were HSV-1 and five were HSV-2 DNA positive. Positive dried blood spot cards were sampled within the interval 5 days before, to 6 days after onset of neonatal herpes. In cases of late onset CNS disease, viremia, was not demonstrable at the age of 3-5 days, the time period when the blood spot cards are normally sampled. Conclusion: Viremia, the prerequisite for demonstrating HSV DNA in dried blood spot cards preceded the onset of illness by up to 5 days and lasted at least up to 6 days thereafter. Analysis of HSV DNA in dried blood spot cards may be of value in the diagnostic arsenal for early onset of neonatal herpes and also have a role in the follow up of a child exposed at delivery. As the majority of the later onset neonatal herpes encephalitis cases are missed, a large-scale neonatal screening does not seem appropriate.

Kamar, N., K. Sandres-Saune, et al. (2004). "Effects of long-term lamivudine therapy in renal-transplant patients." Journal of Clinical Virology **31**(4): 298.

<http://www.sciencedirect.com/science/article/B6VJV-4D34PKK-1/2/9b1aa899c423f4cff33af368f4585fee>

Background: Following renal transplantation (RT), chronic immunosuppression is associated in hepatitis B virus (HBV) (+) patients with a flare-up of the disease, which might be harmful in the long term. Objectives: We report on the effect of long-term lamivudine therapy given at an initial daily dose of 100 mg in 18 HBV (+) RT patients. Results: When lamivudine therapy was commenced, 14 patients (77%) had an increase in their aspartate (AST) and alanine (ALT) aminotransferase levels. During a mean follow-up, under treatment, of 36.5 [plus-or-minus sign] 3.5 months (up to 66 months), 10 patients (55%) had a sustained partial (HBV DNA 5 copies/ml) (n = 4) or complete (HBV DNA n = 6) virological response. Overall, 12 virological breakthroughs were observed. Of those who were HBe Ag(+) prior to lamivudine therapy (n = 4), one seroconverted to HBe Ab during therapy. At the last follow-up, AST and ALT levels were normal in 13 patients. When liver biopsy was repeated during treatment (n = 15), the virological responders showed a significant decrease in total Knodell score from 10 [plus-or-minus sign] 0.6 to 7 [plus-or-minus sign] 1 (P = 0.04), but no significant change in the stage of fibrosis. Conversely, in those patients with high HBV DNA titers, there were no significant changes in the total Knodell score or in the grade of fibrosis. Conclusion: In conclusion, lamivudine therapy is safe in HBV(+)ve renal-transplant patients. However, even if the full and partial virological response rates are still high (55%) in the long term, relapse or primary non-responses occur. The implementation of alternative efficient strategies is warranted.

Koch, N., C. Tamalet, et al. (2001). "Comparison of two commercial assays for the detection of insertion mutations of HIV-1 reverse transcriptase." Journal of Clinical Virology **21**(2): 153.

<http://www.sciencedirect.com/science/article/B6VJV-433PC0B-6/2/f87e44f18d558832caf7358a5664b254>

Insertions in the [beta]3-[beta]4 fingers subdomain of HIV-1 reverse transcriptase (RT) confer cross-resistance to various nucleoside analogs. The detection of these rearrangements in the region of codons 67-70 of RT is of primary importance for adapting and optimizing combination treatment regimen. Recent reports suggest that some genotyping techniques based on the hybridization of oligonucleotide probes may fail to detect insertion mutants of HIV-1 RT. In the present study, we have evaluated the efficiency of two commercial kits TruGene (based on Dye Primer sequencing) and Viroseq (Big Dye Terminator technique) for the detection of insertion mutations. The data were compared with an in-house dRhodamine sequencing method. Overall, all these cycle sequencing techniques were operative in the detection of insertion mutants. The best peak homogeneity in the electrophoregrams was observed with the Dye primer technique. However, specific compression artifacts were frequently encountered with this technique, rendering ambiguous the interpretation of the electrophoregrams in several regions of the sequence. This shortcoming did not occur with dRhodamine Dye terminator or Bigdye terminator cycle sequencing. In any case, a manual inspection of the electrophoregrams is highly recommended, for all types of cycle sequencing techniques, especially for detecting new mutational patterns of the RT and protease genes. Finally, some specific problems were encountered with the softwares provided with both Trugene and Viroseq kits.

Lau, W., R. Onizuka, et al. (1998). "Polymerase chain reaction based assessment of leukoreduction efficacy using a cytomegalovirus DNA transfected human T-cell line." Journal of Clinical Virology **11**(2): 109.

<http://www.sciencedirect.com/science/article/B6VJV-3VXY4S9-G/2/0aad66c6f29d1420d5cbec74c04e8bb4>

Background and Objectives: Detection of CMV DNA by PCR in seropositive blood donors is affected by nucleic acid extraction, amplification conditions and PCR product detection sensitivity. Clinical studies have shown that leukoreduced blood products are as effective as CMV-seronegative blood products in minimizing transfusion-associated CMV infection. We developed a PCR-based test model to assess the efficacy of leukoreduction on the removal of CMV DNA from blood donations. **Materials and Methods:** Whole blood units were spiked with a human Jurkat T-lymphocyte cell line which had been stably transfected with a CMV DNA immediate early sequence. All blood units were either CMV seronegative or shown to be CMV PCR negative. The amount of CMV DNA by PCR before, during and after filtration of blood units with third-generation leukocyte reduction filters were determined using a semi-quantitative adaptation of the Digene SHARP Signal(TM) System Assay (DSSSA). **Results:** Whole blood units spiked with $1-2 \times 10^6$ CMV transfected Jurkat cells contained no detectable CMV DNA after leukoreduction. With a higher inoculum of 2.9×10^8 transfected Jurkat cells per unit, CMV DNA was detected after leukoreduction; however, there was an approximate 3 log decrease in the amount of CMV DNA detected. **Conclusion:** This CMV DNA transfected human Jurkat cell line in conjunction with semi-quantitative CMV PCR may be used to model leukoreduction efficacy and provides evidence that leukoreduction of blood products can decrease the amount of cellular CMV DNA by approximately 3 logs.

Lee, T.-H., D. M. Chafets, et al. (2004). "Quantitation of HTLV-I and II proviral load using real-time quantitative PCR with SYBR Green chemistry." Journal of Clinical Virology **31**(4): 275.

<http://www.sciencedirect.com/science/article/B6VJV-4D2N7V9-1/2/b7cf2fa286d4facb578a432147f3ecf0>

Background: Human T-lymphotropic virus type I (HTLV-I) is linked etiologically with adult T cell leukemia/lymphoma and HTLV-I-associated myelopathy/tropical spastic paraparesis (HAM/TSP).

Human T-lymphotropic virus type II (HTLV-II) is associated with HAM/TSP and, in HIV coinfecting patients only, rare cases of cutaneous T cell lymphoma. Proviral load may be important in the pathogenesis of HTLV-associated disease. Materials and Methods: A real time quantitative PCR assay using SYBR Green intercalation was established. Primers targeting the tax region were standardized against MT2 and MOT cell line DNA for HTLV-I and HTLV-II, respectively. HTLV-I/II copy number was normalized to the amount of cellular DNA by quantitation of the HLA-DQ alpha gene. We measured proviral load in peripheral blood mononuclear cells (PBMCs) in a large cohort of 120 HTLV-I and 335 HTLV-II seropositive former blood donors. We also assessed the intra- and inter-assay reproducibility of the assay. Results: Proviral load for HTLV-I infected patients ranged from 3.1×10^0 to 1.8×10^5 copies/106 PBMCs with a mean of 1.6×10^4 and a median of 3.0×10^3 . HTLV-I was undetectable in 7 of 120 cases (5.8%). Proviral load for HTLV-II infected patients ranged from 1.1×10^0 to 1.0×10^6 copies/106 PBMCs with a mean of 2.8×10^4 and a median of 5.0×10^2 . HTLV-II was undetectable in 31 out of 335 cases (9.3%). Conclusion: The assay has excellent dynamic range from 106 to 100 copies/reaction, good intra- and inter-assay reproducibility, and a lower limit of detection of a single copy per reaction. The sensitivity and high dynamic range allow determination of a broad range of HTLV-I/II proviral load in clinical subjects. This assay will facilitate the study of the relationship between proviral load and pathogenesis.

Legler, T. J., M. Kohler, et al. (1999). "High-throughput extraction, amplification, and detection (HEAD) of HCV-RNA in individual blood donations." *Journal of Clinical Virology* **13**(1-2): 95.

<http://www.sciencedirect.com/science/article/B6VJV-3WMK61W-C/2/579c944e3fe95b7540dcf2f61ee9664c>

Background: High-throughput nucleic acid amplification techniques (NATs) are required for the detection of viral genomes in individual blood donations and might be helpful in any virological laboratory. Objective: To develop and automate a method for the detection of hepatitis C virus RNA in individual blood donations, compatible with the time schedule of routine blood bank screening and product release. Study design: The viral RNA was isolated with the use of target specific capture oligonucleotides and magnetic beads. This extraction method was combined with reverse transcription/amplification (RT/PCR) and fluorescence detection. We adapted our method on a pipetting robot and pipetted all steps in a single room. When the pipetting was completed, microtiter plates were heat-sealed with foils and placed into a thermocycler. Positive reactions were detected with a fluorescent dye in a second room. Aerosols were avoided with programmed slow pipetting steps and with a special device constructed for the removal of the used disposable tips. During a 7 month period, we used this method in routine testing of individual donations prior to the release of all blood components. Results: The total number of 11700 individual donations including platelet concentrates were analysed. We tested up to 192 specimens in one run within 7 h. The frequency of cross-contamination using the automated procedure was 0.1%. Five specimens have been found repeatedly reactive for HCV-RNA, four of these were anti-HCV positive, one sample from a repeat donor was negative in anti-HCV assays. A seroconversion was detectable at his next presentation, 6 months later. Conclusion: In this pilot study, we demonstrate that automated HCV-RT-PCR testing is practicable for individual donations in high-throughput. Additionally, the described PCR approach could easily be adapted to the detection of other viral genomes by the use of specific primers.

Maudru, T. and K. W. C. Peden (1998). "Analysis of a coded panel of licensed vaccines by polymerase chain reaction-based reverse transcriptase assays: A collaborative study." *Journal of Clinical Virology* **11**(1): 19.

<http://www.sciencedirect.com/science/article/B6VJV-3VXY4NF->

Background: A recent publication reporting the presence of low levels of reverse transcriptase (RT) activity in certain vaccines for human use necessitated that regulatory agencies address the issue of whether this RT activity presented a risk to humans. Detection of low levels of RT activity corresponding to fewer than ten virions became possible with the development of highly-sensitive polymerase chain reaction (PCR)-based RT (PBRT) assays. Variations of the PBRT assay were developed in three laboratories. These assays were reported as being at least one million-fold more sensitive than conventional RT assays. **Objective:** To ascertain the sensitivity and reliability of PBRT assays in different laboratories and to determine which vaccine samples possessed RT activity. **Study design:** Coded panels of licensed vaccines together with positive and negative controls was assembled at the Center for Biologics Evaluation and Research (CBER) of the Food and Drug Administration (FDA) and distributed to five cooperating laboratories as well as to our laboratory at CBER. Each laboratory carried out their version of the PBRT assay and submitted the results to the coordinator at CBER. **Results:** Results of the PBRT analyses carried out in the six laboratories are presented. Five of the six laboratories reported results that were highly consistent. RT activity was detected in live attenuated vaccines that were prepared in chick embryo cells (mumps, measles and yellow fever), but very low or undetectable RT activity was found in vaccines produced in mammalian cells (rabies and rubella). Influenza vaccines from several manufacturers included in the panel displayed the most variability, with different products of this inactivated vaccine having differing amounts of RT activity. **Conclusion:** Only vaccines produced in chick embryo cells had significant RT activity. Because RT activity was present in the allantoic fluid of uninfected chick embryos and culture medium from chick embryo fibroblasts, the RT activity arises from the cell substrate used for vaccine production. The PBRT assays were reliably able to detect the low levels of RT activity in chicken-derived vaccines.

Pas, S. D., R. A. de Man, et al. (2002). "The dynamics of mutations in the YMDD motif of the hepatitis B virus polymerase gene during and after lamivudine treatment as determined by reverse hybridisation." *Journal of Clinical Virology* **25**(1): 63.

<http://www.sciencedirect.com/science/article/B6VJV-44PVT3G-2/2/3172db28eabd35c3b69c4b10600c4493>

We have analysed the dynamics of HBV variants related to Lamivudine resistance in 22 chronically infected patients during and after the end of Lamivudine therapy. Thirteen patients had a confirmed methionine mutation in the YMDD region of the reverse transcriptase domain determined by sequence analysis. They responded to therapy having a mean reduction of HBV DNA of 4.55 log (range 2.93-8.91). Nine patients partly responded to therapy, with a small decline of HBV DNA (mean reduction of 3.39 log, range 1.72-5.12) and no indication for an YMDD variant. Samples were re-analysed with a HBV Drug Resistance Line Probe assay (InnoLipa HBV-DR), which detected as low as 10% of a variant HBV population. With this assay, changes in the YMDD region were detected with a mean of 2 weeks (range -8 to 10) earlier than by an increase of HBV DNA levels. Increase of ALT was observed with a mean of 31 weeks (range 29-51) later than the methionine changes in the YMDD motif. Indications for a methionine into valine change could be determined in only one of the partial responders. An unexpected observation was the predominant presence of variant virus populations after end of therapy. In ten patients, we detected the wild type virus with a mean of 14 weeks after end of therapy (range 1-42 weeks). In three patients, no variant virus population could be detected at 25, 36 and 37 weeks, respectively, after cessation of treatment. This observation is important for the inclusion of the so-called naive patients in clinical trials.

Pas, S. D. and H. G. M. Niesters (2002). "My Favourite Reagent: Detection of HBV DNA using real time

analysis." Journal of Clinical Virology **25**(1): 93.

Pas, S. D., S. Noppornpanth, et al. (2005). "Quantification of the newly detected lamivudine resistant YSDD variants of Hepatitis B virus using molecular beacons." Journal of Clinical Virology **32**(2): 166.

<http://www.sciencedirect.com/science/article/B6VJV-4DW3FTG-1/2/7e7114bce50095c613ef1464e90b307b>

A real-time based amplification assay with molecular beacons was used to detect and quantify PCR amplicons to discriminate between the newly described Lamivudine-resistant YSDD variant, a known YIDD variant and wild-type Hepatitis B virus (HBV) DNA in the YMDD region of the polymerase gene. Using this assay, we retrospectively analysed samples from two HBV chronically infected Asian twin sisters, starting 9 weeks before therapy, during and between two periods of treatment with Lamivudine. In order to analyse more accurately the dynamics of variant DNA loads during and after therapy, this real time assay was compared to three other mutation analysis techniques, restriction fragment length polymorphism (RFLP), InnoLipa HBV-DR assay and direct sequence analysis. With this technique, new information on the dynamics of variants during and after therapy was obtained.

Perrons, C., R. Jelley, et al. (2005). "Detection of persistent high risk human papillomavirus infections with hybrid capture II and SPF10/LiPA." Journal of Clinical Virology **32**(4): 278.

<http://www.sciencedirect.com/science/article/B6VJV-4DHX9B0-1/2/d9a41df63ccc8a3bbe049fb6c0adbdbc>

Background: HPV infection in young women is common. However only a certain number of HPV genotypes are oncogenic. It is necessary for high risk HPV infection to persist at the cervix for a considerable time before oncogenesis occurs. Objectives: To look for persistence of high risk HPV in women attending a colposcopy clinic. Two DNA detection methods were used and the results compared to determine the rates of persistent, resolved and acquired infections over a 6-month period. HPV genotyping was used to determine type specific persistence. Study design: One hundred and thirty-eight women were tested for HPV infection when attending the colposcopy clinic at UCLH and then tested again at a subsequent visit approximately 6 months later. HPV DNA was detected by the Digene HC II assay using the high risk probes only and by PCR with the SPF10 primer set. All SPF10 PCR-positive samples were then specifically genotyped by a Line Probe Assay (LiPA) [Kleter et al. 1999. J. Clin. Microbiol. 1999;37:2508]. Results: At entry of the study high risk HPV was detected in 43% of the samples by Digene HC II and in 60% of the samples by SPF10/LiPA. Thirty-eight (28%) of the women had a true persistent infection with the same high risk HPV genotype over a median period of 6.3 months. Nine (7%) women resolved one HR HPV infection after their first colposcopy visit, but obtained a different high risk HPV infection by the time they were tested at their second visit as identified by LiPA. Thirty-seven (27%) of the 138 women had mixed HPV infections, representing 45% of all those infected. Conclusions: The SPF10/LiPA assay detected more high risk infections than the Digene HC II assay. The Digene HC II assay was unable to distinguish between persistent infections with the same high risk genotype and those where the genotype had changed between visits.

Pignatelli, S., P. Dal Monte, et al. (2003). "Intrauterine cytomegalovirus infection and glycoprotein N (gN) genotypes." Journal of Clinical Virology **28**(1): 38.

<http://www.sciencedirect.com/science/article/B6VJV-47CYDC0-1/2/cf3ff0819df9531cfef2c668828bd799>

Background: Human cytomegalovirus (HCMV) clinical isolates display genetic polymorphisms, supposed to be related with strain-specific tissue-tropism and HCMV-induced immunopathogenesis. One recently discovered polymorphic gene is ORF UL73, encoding for the envelope glycoprotein gN. Among HCMV clinical strains, it shows four distinct genomic variants denoted as gN-1, gN-2, gN-3 and gN-4. Objectives: Aims of this study were to assess the prevalence of the different gN types in the populations examined and to investigate the possible relationship between genotypes and severity of congenital CMV disease. Study design: The gN genotyping was carried out by sequencing analysis of the HCMV ORF UL73. Comparisons were made by chi-square test and contingency tables. Results: All the four gN genotypes can cause congenital infections and the overall distribution was as follows: gN-1, 23.6%; gN-2, 1.1%; gN-3, 12.9%; gN-4, 62.4%. None of them seems to be preferentially associated with vertical transmission or with acute outcome of congenital infection. However, considering the chronic outcome and long-term sequelae, there was a statistically significant (PConclusions: HCMV congenital infections, which displayed a prevalence of the gN-1 variants, seem to be associated with favorable chronic outcome.

Piiparinen, H., K. Hockerstedt, et al. (2004). "Comparison of two quantitative CMV PCR tests, Cobas Amplicor CMV Monitor and TaqMan assay, and pp65-antigenemia assay in the determination of viral loads from peripheral blood of organ transplant patients." Journal of Clinical Virology **30**(3): 258.

<http://www.sciencedirect.com/science/article/B6VJV-4BRPC38-1/2/fca40238ecf77b77fe81a9fe288e56bc>

Background: Quantitative PCR assays have become the most common methods in the determination of viral load during cytomegalovirus (CMV) infection of transplant patients. However, usually these tests are still quite time-consuming and labor-intensive which diminishes their utility of these tests in routine diagnostic laboratories. Objectives: The objective of this study was to develop a quantitative CMV PCR test which is time-saving and easy to perform for the detection and monitoring of CMV infection of transplant patients. Study design: The quantitative real time CMV PCR assay using TaqMan chemistry and an automated sample preparation system, MagNA Pure LC, was developed. The designed quantitative CMV test was compared to commercial quantitative PCR test, Cobas Amplicor Monitor, in the determination of CMV DNA loads in plasma samples of liver and kidney transplant patients. The results were also correlated with the CMV pp65-antigenemia test. The clinical material of 270 blood specimens of transplant patients were tested using these two PCR methods and pp65-antigenemia test in parallel. Plasma samples were used for PCR assays and leucocytes for the antigenemia test. Results: The TaqMan assay described was easy to perform, it was rapid (3-4 h) and hands-on time needed for performing the test was short. The detection limit of the assay was 250 copies/ml

(cps/ml) plasma and the linear range up to 25,000,000 cps/ml. TaqMan assay was the most sensitive test detecting 92% of the CMV positive findings. Cobas Monitor detected 80% and pp65 test 88% of the positive findings. The correlations between TaqMan and antigenemia assays, and between Cobas Amplicor and antigenemia were statistically significant and high, $R=0.84$ ($PR=0.80$) ($PR=0.64$, P Conclusions: The developed real time TaqMan assay was rapid and easily performed and could be the best alternative for the diagnosis of CMV infection and monitoring of liver and kidney transplant patients.

Poon, L. L. M., K. H. Chan, et al. (2003). "Early diagnosis of SARS Coronavirus infection by real time RT-PCR." Journal of Clinical Virology **28**(3): 233.

<http://www.sciencedirect.com/science/article/B6VJV-49KYTJ5-3/2/96dc5a1dab0e5a8d02df7d06c4fe876c>

Background: A novel coronavirus was recently identified as the aetiological agent of Severe Acute Respiratory Syndrome (SARS). Molecular assays currently available for detection of SARS-coronavirus (SARS-Cov) have low sensitivity during the early stage of the illness. Objective: To develop and evaluate a sensitive diagnostic test for SARS by optimizing the viral RNA extraction methods and by applying real-time quantitative RT-PCR technology. Study design: 50 nasopharyngeal aspirate (NPA) samples collected from days 1-3 of disease onset from SARS patients in whom SARS CoV infections was subsequently serologically confirmed and 30 negative control samples were studied. Samples were tested by: (1) our first generation conventional RT-PCR assay with a routine RNA extraction method (Lancet 361 (2003) 1319), (2) our first generation conventional RT-PCR assay with a modified RNA extraction method, (3) a real-time quantitative RT-PCR assay with a modified RNA extraction method. Results: Of 50 NPA specimens collected during the first 3 days of illness, 11 (22%) were positive in our first generation RT-PCR assay. With a modification in the RNA extraction protocol, 22 (44%) samples were positive in the conventional RT-PCR assay. By combining the modified RNA extraction method and real-time quantitative PCR technology, 40 (80%) of these samples were positive in the real-time RT-PCR assay. No positive signal was observed in the negative controls. Conclusion: By optimizing RNA extraction methods and applying quantitative real time RT-PCR technologies, the sensitivity of tests for early diagnosis of SARS can be greatly enhanced.

Preiser, W., N. S. Brink, et al. (2003). "Development and clinical application of a fully controlled quantitative PCR assay for cell-free cytomegalovirus in human plasma." Journal of Clinical Virology **26**(1): 49.

<http://www.sciencedirect.com/science/article/B6VJV-4604319-1/2/d9f3013c29d95e32448f3b7ff624eadc>

Background: Cytomegalovirus (HCMV) disease continues to be a major problem in certain patient groups, including bone marrow transplant (BMT) recipients. The quantification of HCMV genome is clinically useful for the diagnosis of HCMV disease, for the virological surveillance of high-risk patients and for monitoring antiviral therapy. Objectives: To develop a novel, robust, and fully controlled PCR (qPCR) for the quantification of HCMV DNA in plasma samples and to demonstrate its clinical usefulness in the BMT setting. Study design: The newly developed HCMV qPCR employs cell culture-derived murine CMV as an internal control for both extraction and amplification. Following amplification using common primers, detection of both internal control and patient HCMV amplicons is by specific probes and a chemiluminescence microtitre plate system. Its performance was evaluated using the routine non-quantitative nested HCMV PCR on whole blood (NQPCR) and correlated with clinical events such as disease and antiviral therapy. Results: A high level of concordance (85.1%) was found between the novel assay and the

NQPCR, with the qPCR being slightly more sensitive. The samples giving discordant results generally had levels of HCMV DNA close to the limit of detectability or had been stored for prolonged periods. Conclusions: The use of plasma as an analyte by the newly developed assay avoids the detection of cell-associated virus. On the other hand, testing a comparatively large volume of plasma ensures that sensitivity is not compromised by not detecting cell-associated HCMV. In a small preliminary evaluation in BMT recipients, changes in HCMV 'viral load' correlated with initiation and discontinuation of antiviral therapy and were biologically plausible.

Puppe, W., J. A. I. Weigl, et al. (2004). "Evaluation of a multiplex reverse transcriptase PCR ELISA for the detection of nine respiratory tract pathogens." *Journal of Clinical Virology* **30**(2): 165.

<http://www.sciencedirect.com/science/article/B6VJV-4BBKHBS-4/2/0a35233520b490dced01da781d803955>

Background: A multiplex reverse transcription (RT) polymerase chain reaction combined with a microwell hybridization assay (m-RT-PCR-ELISA) was previously developed to detect nine different microorganisms: enterovirus (EV), influenza virus type A (IVA) and type B (IVB), respiratory syncytial virus (RSV), parainfluenzavirus type 1 (PIV1) and type 3 (PIV3), adenovirus (AV), *Mycoplasma pneumoniae* (Mpn), *Chlamydia pneumoniae* (Cpn) in a single test. These organisms do not usually colonize the respiratory tract of humans, but, if present, it may be assumed they are involved in respiratory disease. Objectives and study design: The m-RT-PCR-ELISA was tested on (i) culture supernatants of unknown contents, (ii) by determining the analytical sensitivity of 10-fold serial dilutions of culture supernatants and (iii) by determining clinical sensitivity in a retrospective study on 411 clinical specimens. The specimens were re-tested in parallel by m-RT-PCR-ELISA versus the gold standard culture and immunofluorescence, and versus individual RT-PCR. Results: (i) The 9-valent m-RT-PCR-ELISA shows 83% to 100% concordant results on 103 culture supernatants containing different organisms. (ii) The analytical sensitivity was as follows: higher sensitivity of the 9-valent m-RT-PCR-ELISA in comparison to culture in the cases of PIV3, IVA and IVB (factor 10) and AV and EV (factor 100), and lower sensitivity in case of RSV and PIV1 (factor 10). (iii) The agreement with the gold standard in the kappa statistic was excellent for RSV ($\kappa=0.937$), IVA ($\kappa=0.940$), very good for PIV1 ($\kappa=0.914$), IVB ($\kappa=0.907$) and satisfactory for PIV3 ($\kappa=0.410$). For AV, EV and Mpn the m-RT-PCR-ELISA preliminary could be qualified as very good, based on the data derived on culture supernatants. Information about the validity for Cpn is limited. Conclusion: The m-RT-PCR-ELISA is a feasible, sensitive and specific method for detection of a broad spectrum of organisms. It is suitable for individual as well as epidemiological diagnosis.

Rautenberg, P., C. Lubbert, et al. (1999). "Evaluation of the AmpliSensor PCR and the SHARP signal detection system for the early prediction of symptomatic CMV infection in solid transplant recipients." *Journal of Clinical Virology* **13**(1-2): 81.

<http://www.sciencedirect.com/science/article/B6VJV-3WMK61W-B/2/d0ff9f0a42ffc3155735fff6c804ccd>

Background: Cytomegalovirus (CMV) is associated with high morbidity and mortality in transplant patients. Specific antiviral treatment at an early stage of CMV infection may effectively ameliorate, but not eliminate CMV disease in these patients. Presently, the pp65 antigenemia test on peripheral leukocytes is the method most widely used for predicting and monitoring transplant patients for active CMV infection. Nucleic acid amplification methods are less well defined since they lack standardisation. Objective: A seminested fluorometric PCR assay (AmpliSensor-CMV, BAG, Germany) and a one-step PCR with a signal-amplification step (SHARP, Abbott, Germany) specific for the fragments of the CMV UL 122 and UL 123 genes, respectively, were evaluated for

the early diagnosis of CMV infection. Design: A total of 26 recipients of heterogeneous solid organs were monitored prospectively for a median of 99 days after transplantation. By testing 371 clinical samples parallel with the pp65-antigen assay and IgM and IgG EIA assays the sensitivity, specificity, correlation and quantitation potential of both PCRs was evaluated. Results: Eight out of 26 patients developed active CMV infection. A total of 48 samples of these patients exceeded a CMV-DNA load threshold of 15 genome equivalents/10⁵ leukocytes (AmpliSensor-CMV) and 41 samples exceeded the critical cut-off for the SHARP system. The AmpliSensor PCR exceeded its threshold consistently before the clinical onset of CMV disease (median 8 days). There was very good agreement between symptomatic CMV infection in patients and AmpliSensor-PCR, SHARP PCR, and pp65-antigen results (κ -coefficient > 0.900). IgM and IgG EIA showed moderate agreement (κ -coefficient = 0.591 and 0.552, respectively). Conclusion: Both PCRs and pp65 antigen assay correlated significantly better with CMV disease than serodiagnosis. The AmpliSensor PCR allowed more precisely than the SHARP system a quantitative determination of viral load and an early and reliable prediction of active CMV infection. The use of AmpliSensor PCR may improve the diagnosis and management of active CMV infection in organ transplant recipients.

Sagir, A., O. Adams, et al. "SEN virus seroprevalence in HIV positive patients: association with immunosuppression and HIV-replication." *Journal of Clinical Virology* **In Press, Corrected Proof** <http://www.sciencedirect.com/science/article/B6VJV-4F0GC8W-1/2/00f60ac92d166f5015f6642059c6923f>

Background: Patients infected with HIV are often co-infected with other viruses. SEN virus (SENV) was isolated from a HIV positive patient with intravenous drug use and post-transfusion hepatitis. SENV strains D and H seem to be relevant for the development of post-transfusion hepatitis. We compared the prevalence of SENV strains D and H and the viral load of SENV H in HIV-infected patients with healthy blood donors. The results were correlated with clinical markers such as HIV stage, CD4 cell count, HIV-RNA positivity, HAART or the transmission mode in HIV infected individuals. Objectives: Blood samples of 143 HIV-positive patients were analysed and compared with a control group of 122 healthy blood donors. SENV D and -H was detected by PCR. Results: SENV was detectable in 15.4% (22/143) of HIV-positive patients compared to 10.4% (12/122) in the control group ($P = 0.18$). SENV H DNA-levels were significantly higher in HIV-positive patients ($P = 0.01$). The prevalence in patients with CD4 cells less than 200/mm³ was 31% (13/42), compared to 12.3% (8/65) in cases with CD4 cells between 200 and 500/mm³, and 2.8% in cases with CD4 cells above 500/mm³ ($P = 0.002$ for CD4 cells 200, $P = 0.031$ for CD4 cells 500). Prevalence of these strains was not significantly influenced by CDC stages. SENV was detected significantly more frequent in patients with detectable HIV-RNA ($P = 0.005$). Patients undergoing HAART were significantly less frequent positive for SENV D or -H ($P = 0.029$) than patients without HAART. In a multivariate analysis using a logistic regression model HIV-RNA positivity and CD4 cell count were identified as independent factors for SENV prevalence. Conclusion: SENV (D and H) prevalence is not significantly higher in HIV-positive patients in comparison to healthy blood donors. SENV prevalence depends on CD4 cell count and HIV-RNA.

Sarcinella, L., T. Mazzulli, et al. (2002). "Cytomegalovirus glycoprotein B genotype does not correlate with outcomes in liver transplant patients." *Journal of Clinical Virology* **24**(1-2): 99.

<http://www.sciencedirect.com/science/article/B6VJV-44MFSG6-H/2/38fc78f83eba978953332a7df73b77e4>

Background: Based on sequence variation in the UL55 gene that encodes glycoprotein B (gB), human cytomegalovirus (CMV) can be classified into four gB genotypes. Previous studies have

suggested there could be an association between CMV gB genotype and clinical outcome in transplant patients. Objectives: The goal of this study was to determine the distribution of gB genotypes in a cohort of liver transplant recipients with CMV infection and the effect of gB type on clinical outcomes including CMV disease and rejection. Study design: DNA was extracted directly from the blood of 58 liver transplant recipients with CMV infection. The gB genotype of CMV was determined using the polymerase chain reaction to amplify a region of UL55, followed by restriction analysis based on HinfI and RsaI digestion. Results were correlated with CMV viral load, symptomatic disease, and development of acute rejection. Results: The distribution of CMV gB genotypes was: gB1, 15/58 (25.9%); gB2, 16/58 (27.6%); gB3, 21/58 (36.2%); gB4, 2/58 (3.4%) and four patients (6.9%) had mixed infection. No correlation between CMV genotype and peak CMV viral load was observed. Symptomatic CMV disease developed in 25/58 (43.1%) patients and 26/58 (44.8%) had acute rejection. The rate of CMV disease and acute graft rejection in patients infected with the different CMV gB genotypes was not significantly different. However, all four patients with infection with a mixture of CMV gB genotypes developed progression to CMV disease ($P=0.030$). Conclusions: The gB genotype did not correlate with peak CMV viral load and with the development of CMV disease or acute rejection following liver transplantation.

Schwaiger, M. and P. Cassinotti (2003). "Development of a quantitative real-time RT-PCR assay with internal control for the laboratory detection of tick borne encephalitis virus (TBEV) RNA." Journal of Clinical Virology **27**(2): 136.

<http://www.sciencedirect.com/science/article/B6VJV-47GYM1T-7/2/0774bb9e027fc813d0abee7bce4471ef>

Background: Tick borne encephalitis virus (TBEV), is a human flavivirus causing tick borne encephalitis (TBE), a viral infection of the central nervous system endemic in Europe and Asia. Objectives: To develop a reverse transcription polymerase chain reaction (RT-PCR) assay based on quantitative real-time RT-PCR technology (TaqMan) for detection and quantification of TBEV RNA. The test includes an internal control (IC) to avoid false negative results. Study design: The system was established and validated using wild-type (WT) non-infectious synthetic RNA representing a fragment of the 3' non-coding region of the TBEV genome. In addition, synthetic RNA differing from the WT synthetic RNA by a unique probe binding region was used as IC to monitor the overall efficiency of the RT-PCR. Results: The analytical sensitivity of the assay was at least ten copies of the TBEV synthetic transcript in presence of 50 copies of the IC. Successful amplification was obtained for different strains within the TBEV complex (Hypr, Hochosterwitz, Laibach, Elsass=Alsace, ZZ9, Wladiwostok). Among 14 serum and 21 cerebrospinal fluid (CSF) samples obtained from 28 patients with clinical suspicion of TBEV 1 CSF sample tested positive for TBEV RNA. In addition, no TBEV RNA could be detected in blood samples obtained from three vaccinated people 1 and 3 days post-vaccination. Thus indicating that a positive result is unlikely to be caused by recent vaccination. Conclusions: A quantitative, highly sensitive and specific real-time RT-PCR assay has been developed for the detection of TBEV RNA. Inclusion of an IC is important to monitor the possible occurrence of false-negative results caused by the presence of inhibitory factors. This assay should be an important asset for the routine laboratory detection of TBEV RNA.

Sen, A., N. Kobayashi, et al. (2000). "Amplification of various genes of human group B rotavirus from stool specimens by RT-PCR." Journal of Clinical Virology **17**(3): 177.

<http://www.sciencedirect.com/science/article/B6VJV-416C03J-5/2/15a86bfaa1a404ee084efc080f82cddb>

Background: The detection of the human group B rotavirus (HuGBR) CAL strain from India has given us an opportunity to design suitable primers for the detection of HuGBR since CAL is the second HuGBR detected until now, the Chinese Adult Diarrhoea Rotavirus (ADRV) being the first reported human pathogen belonging to this group of viruses. The primers described here may thus be used for the detection of human group B rotaviruses by reverse transcription-PCR (RT-PCR) in a diagnostic laboratory. Objective: To establish a set of primers suitable for the detection of various genes of human group B rotaviruses using a rapid RT-PCR assay. Study design: Until recently, the Chinese ADRV strain was the only HuGBR strain that had been partially sequenced by cloning various viral genes using vector-specific primers. Consequently, there are very few reports in the literature describing primers that may be used for the detection of HuGBR viruses using RT-PCR in a clinical laboratory. The sequences of various genes from the ADRV strain that had been submitted to the nucleotide sequence database GenBank were analyzed in order to design several putative detection primer pairs for an RT-PCR assay. The rationale was to amplify the cognate genes from five isolates of the HuGBR CAL strain (CAL-1 to CAL-5) that have been detected to date from India. Primers that resulted in a specific product of the expected size from the CAL isolates were used to standardize a protocol for amplifying various genes of the CAL isolates under identical reaction conditions. Results: Out of several synthetic oligonucleotides designed, 12 were found to be satisfactory for the amplification of gene segments 4, 5, 6, 7, and 9 from the five CAL isolates and are presented here. A set of previously described primers that have been shown to be specific for human group B rotavirus gene segment 8 were also found to amplify the cognate gene from the CAL isolates. All the reactions were carried out using the same thermal cycling conditions. Conclusions: The extreme virulence potential of HuGBR has been documented in several epidemics in China. Until recently, the Chinese ADRV strain was the only known HuGBR strain. As there have not been any reports of HuGBR infections outside China, there are no consensus nucleotide sequences available for HuGBR that may be used to validate primers for the detection of HuGBR. Here we report a set of 12 primer sequences that were designed from ADRV sequences and also found to amplify various genes from the different CAL isolates and hence may represent consensus primers suitable for the detection of HuGBR.

Smith, I. L., J. A. Northill, et al. (2002). "Detection of Australian bat lyssavirus using a fluorogenic probe." Journal of Clinical Virology **25**(3): 285.

<http://www.sciencedirect.com/science/article/B6VJV-46YXTNN-1/2/50322ec858befaa15e57a4c54e7050ae>

Background: Australian bat lyssavirus (ABLV) has been transmitted to humans following a scratch or bite from an infected bat in two cases. Following a scratch or bite to a person, the bat is usually submitted for testing and diagnosis is made using a direct fluorescent antibody test on a brain smear. A nested RT-PCR assay has also been utilised to confirm diagnosis. If positive for lyssavirus, post-exposure prophylaxis is administered. Objectives: The TaqMan(TM) assay was developed to improve the diagnosis of ABLV infection, following problems encountered with the generation of spurious PCR products in the nested RT-PCR and also to reduce the high risk of contamination inherent with nested PCRs. Study design: RNA was extracted from 161 bat brains and the samples were compared using a conventional RT-PCR and the TaqMan based assay. Samples from a patient with an ABLV infection collected antemortem and postmortem were also tested. Results: The sensitivity of the new TaqMan based PCR assay compared favourably with the nested PCR previously in use in our laboratory. This assay was able to detect RNA in samples collected antemortem and postmortem for the diagnosis of a human case of ABLV. Conclusions: The major advantage of the TaqMan(TM) based assay was the speed of diagnosis with a result within minutes of completing the PCR (a result within 4 h of receiving the specimen). This test greatly reduces the chance of false positives through the elimination of second-round PCR and the requirement for agarose gels. The assay is sensitive and specific and should be invaluable for future antemortem and postmortem diagnosis of ABLV infection in humans.

Song, L. H., V. Q. Binh, et al. (2003). "Serum cytokine profiles associated with clinical presentation in Vietnamese infected with hepatitis B virus." Journal of Clinical Virology **28**(1): 93.

<http://www.sciencedirect.com/science/article/B6VJV-47RBSYB-4/2/6c08d3f7a693d6210e426733385b29d5>

Background/objectives: An ineffective cytokine response is thought to be one of the reasons for the failure to suppress hepatitis B virus (HBV) replication and to eliminate the virus. We investigated the serum levels of interleukin (IL)-6, IL-10, IL-12, and interferon (IFN)-[gamma] in HBV-infected Vietnamese patients to determine whether they were related to the outcome of HBV infection. **Study design:** Samples from a total of 154 HBV-infected patients with well-characterised clinical profiles and 56 healthy controls were assessed. **Results:** Serum IL-6 levels, which were inversely correlated with transaminase levels, were highest in patients with liver cirrhosis (LC) and hepatocellular carcinoma (HCC) and lowest in those with either asymptomatic (ASYM), acute or chronic HBV, and thus, represented the best marker of HBV-related clinical progression. Compared with the healthy control group, serum IL-12 was uniformly elevated in all HBV-infected patients apart from those with ASYM infections, implying no impairment of production of this cytokine in HBV-infected individuals. Serum IL-10 and IFN-[gamma] levels, however, were uniformly low and showed no association with clinical presentation. Cytokine profiles were not influenced by the presence of hepatitis B e antigen (HBeAg). **Conclusions:** Serum IL-6 and IL-12 but not IL-10 and IFN-[gamma] are associated with the clinical presentation in HBV-infected Vietnamese patients.

Stocher, M., V. Leb, et al. (2002). "A simple approach to the generation of heterologous competitive internal controls for real-time PCR assays on the LightCycler." Journal of Clinical Virology **25**(Supplement 3): 47.

<http://www.sciencedirect.com/science/article/B6VJV-47C3NXK-7/2/c7e743df374d09e92db3ff575e657e31>

Background: The real-time PCR technology allows convenient detection and quantification of virus derived DNA. This approach is used in many PCR based assays in clinical laboratories. Detection and quantification of virus derived DNA is usually performed against external controls or external standards. Thus, adequacy within a clinical sample is not monitored for. This can be achieved using internal controls that are co-amplified with the specific target within the same reaction vessel. **Objectives:** We describe a convenient way to prepare heterologous internal controls as competitors for real-time PCR based assays. **Study design:** The internal controls were devised as competitors in real-time PCR, e.g. LightCycler-PCR. The bacterial neomycin phosphotransferase gene (neo) was used as source for heterologous DNA. Within the neo gene a box was chosen containing sequences for four differently spaced forward primers, one reverse primer, and a pair of neo specific hybridization probes. Pairs of primers were constructed to compose of virus-specific primer sequences and neo box specific primer sequences. Using those composite primers in conventional preparative PCR four types of internal controls were amplified from the neo box and subsequently cloned. **Results:** A panel of the four differently sized internal controls was generated and tested by LightCycler PCR using their virus-specific primers. All four different PCR products were detected with the single pair of neo specific FRET-hybridization probes. **Conclusion:** The presented approach to generate competitive internal controls for use in LightCycler PCR assays proved convenient and rapid. The obtained internal controls match most PCR product sizes used in clinical routine molecular assays and will assist to discriminate true from false negative results.

Tonon, S. A., M. A. Picconi, et al. (2001). "Physical status of the E2 human papilloma virus 16 viral gene in cervical preneoplastic and neoplastic lesions." Journal of Clinical Virology **21**(2): 129.

<http://www.sciencedirect.com/science/article/B6VJV-433PC0B-3/2/e0af9fc63749666b9a43ae511db58ca9>

Background: Integration of human papilloma virus (HPV) 16 DNA is considered an important genetic change in cervical lesion progression towards ICC. The viral E2 gene is often disrupted by this process, releasing suppression of viral E6/E7 oncogenes, a key factor for oncogenic progression. Objectives: To evaluate the physical status of HPV 16 E2 gene in cervical preneoplastic and neoplastic lesions and its relation with lesion severity. Study design: A sensitive PCR approach for the detection of an intact E2 HPV 16 gene in infected epithelial cells from the cervix with low grade squamous intraepithelial lesion (LGSIL), high grade squamous intraepithelial lesion (HGSIL) and invasive cervical carcinoma (ICC) diagnosis was applied. The correlation between gene disruption and lesion stage was examined. Results: Sixty-two LGSIL, 39 HGSIL and 24 ICC samples were analyzed. Fifty-seven LGSIL [92%], 13 HGSIL [33%] and 4 ICC [17%] showed results compatible with an intact E2 gene, while 5 LGSIL [8%], 26 HGSIL [67%] and 20 ICC [83%] samples gave no signal. Conclusions: HPV 16 E2 gene disruption showed a positive correlation with cervical lesion progression, particularly from LGSIL to HGSIL. Although additional genetic events are very likely to be needed for HGSIL to ICC progression, the E2 gene disruption is a putative early marker to consider in the prognostic analysis of HPV 16 chronically infected women.

Torfason, E. G., Gueth, et al. (2002). "Polymerase chain reaction for laboratory diagnosis of orf virus infections." Journal of Clinical Virology **24**(1-2): 79.

<http://www.sciencedirect.com/science/article/B6VJV-44MFSG6-D/2/a29a0db4914205b5fa880a097795af9c>

Background: The orf virus of sheep and goats is one of several zoonotic parapoxviruses. In the ovine/caprine host it causes contagious ecthyma (contagious pustular dermatitis, scabby mouth), but in humans it normally causes solitary or clustered orf lesions, typically on hands, arms or face. In addition to disease in the animals, the virus can be quite a nuisance as an occupational hazard in farmers and butchers. Clinical diagnosis is often possible, but laboratory diagnosis is sometimes necessary. For virus isolation, primary ovine or bovine cells, not routinely present, are needed. Serological methods exist, but electron microscopy is the most commonly used method. Objectives: To develop a reliable method for the laboratory diagnosis of orf zoonoses, without virus culture and without access to an electron microscope. Study design: A suitable primer pair was designed for orf polymerase chain reaction (PCR), using the Oligo software and sequence information from GenBank. Orf positive controls and specimens were kindly provided by several public health centers. Molluscum contagiosum specimens were provided by a dermatologist. HSV-1, HSV-2 and VZV positive swab specimens came from our routine diagnostic service. Asymptomatic skin specimens were obtained from sheep heads from the abattoir, and swab specimens from the heads of asymptomatic sheep. Selected amplified orf PCR positive specimens were sequenced to ensure the authenticity of the PCR products. Orf positive specimens were sent to another laboratory for electron microscopy. Results and conclusions: A robust PCR was developed, with very small inter-run variation. All specificity demands were met, and the sensitivity seems to be good or excellent. All negative specificity controls from cell cultures and non-orf viruses were negative. Twenty-two (95.7%) of 23 scab or swab specimens with suspected orf etiology were orf PCR positive. Five of eight skin specimens from sheep heads from the abattoir were positive, and all 11 swab specimens from asymptomatic sheep were negative. Electron microscopy demonstrated orf-like particles in orf-PCR positive specimens. This PCR seems to be suitable as a diagnostic test for orf in humans, but asymptomatic virus shedding in sheep or goats may complicate veterinary applications of the assay.

Verstrepen, W. A., P. Bruynseels, et al. (2002). "Evaluation of a rapid real-time RT-PCR assay for detection of enterovirus RNA in cerebrospinal fluid specimens." Journal of Clinical Virology **25**(Supplement 1): 39.

<http://www.sciencedirect.com/science/article/B6VJV-45TY876-1/2/e90b30d9c98812640c2c978f5c901cc3>

Background: We previously described the characteristics of a single-tube real-time enterovirus reverse transcriptase polymerase chain reaction (RT-PCR) assay based on a fluorogenic probe and primers directed to highly conserved sequences in the 5'-untranslated region (UTR) of the enterovirus genome. Objectives: To evaluate the performance of the assay on a larger number of cerebrospinal fluid (CSF) specimens from patients suspected of having viral meningitis. Study design: Real-time enterovirus RT-PCR and viral culture were performed on CSF specimens received from March 2000 to November 2001. Patient records were retrospectively reviewed for final clinical diagnosis. Results: From the 186 CSF specimens tested, culture was positive for enterovirus in 31 cases, whereas real-time RT-PCR detected enterovirus RNA in 45 CSF specimens. The sensitivity of real-time RT-PCR in relation to the clinical diagnosis of viral meningitis was 72.6%, whereas the sensitivity of viral culture reached only 57.4%. Enterovirus RNA was also found in a number of specimens with low leukocyte counts. Conclusions: We confirm that the real-time enterovirus RT-PCR assay for CSF specimens is significantly more sensitive than viral culture.

Ward, C. L., M. H. Dempsey, et al. (2004). "Design and performance testing of quantitative real time PCR assays for influenza A and B viral load measurement." Journal of Clinical Virology **29**(3): 179.

<http://www.sciencedirect.com/science/article/B6VJV-492W0P8-1/2/7575686b4ad97fc4190e40940c372112>

Background: The antiviral effect of anti-influenza drugs such as zanamivir may be demonstrated in patients as an increased rate of decline in viral load over a time course of treatment as compared with placebo. Historically this was measured using plaque assays, or Culture Enhanced Enzyme Linked Immunosorbent Assay (CE-ELISA). Objectives: to develop and characterise real time quantitative PCR (qPCR) assays to measure influenza A and B viral load in clinical samples, that offer improvements over existing methods, in particular virus infectivity assays. Study design: The dynamic range and robustness were established for the real time qPCR assays along with stability of the assay components. Cross validation of the real time PCR assays with CE-ELISA was performed by parallel testing of both serial dilutions of three different subtypes of cultured virus and a panel of influenza positive throat swab specimens. Results: the assays were specific for influenza A and B and the dynamic ranges were at least seven logs. The assay variability was within acceptable limits but increased towards the lower limit of quantification, which was 3.33 log₁₀ viral cDNA copies/ml of virus transport medium (ten viral RNA copies/PCR). The components of the assay were robust enough to withstand extended

storage and several freeze-thaw cycles. For the real time PCR assays the limit of quantification was equivalent to the virus infectivity cut off, which equates to a 93-fold increase in sensitivity. Conclusion: Well characterised real time PCR assays offer significant improvements over the existing methods for measuring the viral load of strains of influenza A and B in clinical specimens.

Yancoski, J., S. Danielian, et al. (2004). "Quantification of Epstein-Barr virus load in Argentinean transplant recipients using real-time PCR." Journal of Clinical Virology **31**(1): 58.

<http://www.sciencedirect.com/science/article/B6VJV-4CDJNN4-1/2/551efab17df8d5383a4ae57bf62f4bd5>

Background: Post-transplant lymphoproliferative disease (PTLD) is a frequent and severe Epstein-Barr virus (EBV)-associated complication in transplant recipients that is caused by suppression of T-cell function. Objective: Evaluation of the diagnostic value of EBV DNA load in non-fractionated whole blood samples (n=297) from 110 pediatric transplant patients by real-time PCR. Results and conclusions: Patients with PTLD had a median viral load of 1.08×10^5 copies/ml blood (n=24), which was significantly higher compared with patients without PTLD (median: 50 copies/ml blood, n=273, PPP=0.0391). These patients who had a high viral load may benefit from a close follow-up of the viral burden.

Zhou, L., T. C. Harder, et al. (1999). "Rapid detection by reverse hybridization of mutations in the UL97 gene of human cytomegalovirus conferring resistance to ganciclovir." Journal of Clinical Virology **13**(1-2): 53.

<http://www.sciencedirect.com/science/article/B6VJV-3WMK61W-7/2/44c76d63117c8bfd8e6bc132c86bde35>

Background of study: Diseases due to human cytomegalovirus (HCMV) infection constitute a major threat in marrow and solid organ transplant recipients. Ganciclovir (GCV) is widely used in prophylaxis and pre-emptive therapy of active HCMV infection. Resistance to ganciclovir (GCV) may arise at variable frequency under GCV therapy and is conferred by mutations (i) in the UL97 gene (codons 460, 520, and 591-607) encoding a phosphotransferase which is essential for monophosphorylation of GCV and, to a lesser extent, (ii) in the UL54 gene coding for the DNA polymerase of HCMV. Objective: The purpose was to develop a rapid assay to screen for emerging GCV resistance mutations in the UL97 gene of HCMV whereby avoiding virus isolation and nucleotide sequencing procedures. Study design: A nested PCR (nPCR) amplifying UL97 codons 450-672 was developed. Nested amplicons were subsequently sequenced directly. Oligonucleotides for use in a reverse hybridization assay were designed to detect relevant non-synonymous mutations at codons UL97 460, 520, 603 and 607. Strain AD169 served as a wild-type control. Results: UL97-specific nPCR amplicons were obtained from 18 EDTA blood samples of ten transplant recipients receiving GCV for more than 30 days. In three consecutive samples from a single patient a GCV resistance mutation at codon 603 (C->W) was detected. In addition, two out of four cell culture-adapted HCMV isolates known to exhibit GCV resistance in vitro revealed mutations at codons 460 (M->V) and 607 (C->Y), respectively. By reverse hybridization a discrimination of single nucleotide changes at codons 460, 520, 603 and 607 was possible whereby matching exactly the results of the nucleotide sequence analysis for all 23 amplicons examined. Conclusions: Reverse hybridization appeared to be a rapid and convenient alternative to nucleotide sequencing when screening the UL97 gene of HCMV for selected markers of GCV resistance.

Narama, I., Y. Kobayashi, et al. (2005). "Pigmented Cutaneous Papillomatosis (Pigmented Epidermal Nevus) in Three Pug Dogs; Histopathology, Electron Microscopy and Analysis of Viral DNA by the Polymerase Chain Reaction." Journal of Comparative Pathology **132**(2-3): 132.

<http://www.sciencedirect.com/science/article/B6WHW-4F6CRBN-3/2/1f5a8a0efb70018e602710da697325c7>

Summary Canine pigmented epidermal nevus (CPEN) is a skin disorder of some breeds of dog characterized by multiple black plaques of the haired and non-haired skin. Three cases of pigmented cutaneous papillomatosis (previously described also as CPEN) in pug dogs were investigated histopathologically, immunohistochemically and electron microscopically. Additionally, DNA analyses with the polymerase chain reaction (PCR) were performed in two cases. Many nuclei of the stratum granulosum were diffusely immunolabelled for specific structural antigens of bovine papillomavirus (subgroup A), but nuclear inclusion bodies were not detected by retrospective examination of haematoxylin and eosin-stained sections of the affected skin. Aggregates of small numbers of viral particles (ranging from 37 to 43 nm in diameter) with a hexagonal structure were sparsely scattered throughout the nuclei of some of the superficial keratinocytes. PCR amplification targeted for the L1 gene of papillomavirus cloned from a case of CPEN yielded an expected fragment of 194-bp in the two CPEN cases examined but not in a case of canine oral papilloma.

Schmidbauer, S. M., M. Venner, et al. (2004). "Compensated Overexpression of Procollagens [alpha]1(I) and [alpha]1(III) Following Perilla Mint Ketone-induced Acute Pulmonary Damage in Horses." Journal of Comparative Pathology **131**(2-3): 186.

<http://www.sciencedirect.com/science/article/B6WHW-4CPM121-1/2/b38125619b296ea4fc709c8aab578a7b>

Interstitial lung disease with chronic fibrosis is a frequent cause of reduced performance in horses. The aim of this study was to establish a model of acute alveolar damage and interstitial lung disease in horses that could be used to monitor the histopathological lesions and changes in expression levels of genes relevant to pulmonary fibrosis. Six adult horses were given a single intravenous injection (6 mg per kg body weight) of perilla mint ketone (PMK). Transthoracic lung biopsy samples (1 x 0.2 x 0.2 cm) were collected before and after (days 1, 4, 8, 11, 15, 18, 22, 25 and 29) the administration of PMK. Light and electron microscopy revealed severe acute alveolar damage (days 1 to 4), proliferation of type II pneumocytes (days 4 to 11) and finally complete healing at about day 18. However, unexpectedly severe clinical signs necessitated euthanasia in two horses on days 9 and 11. The expression levels of the collagen genes COL1A1 and COL3A1 as well as transforming growth factor (TGF)-[beta] were examined in the biopsy samples by reverse transcription-real time quantitative polymerase chain reaction. COL1A1 and COL3A1 gene expressions were upregulated (3- and 17-fold, respectively) between days 1 and 29 in all six horses, whereas TGF-[beta] was upregulated in two horses (2- and 4-fold, respectively), between days 4 and 18. Although the gene expression analyses indicated a strong activation of the pro-fibrotic pathway, no interstitial fibrosis was seen in any horse. A complete necropsy performed on day 60 revealed complete recovery of the lungs of the four surviving horses, with no evidence of fibrosis. Unidentified compensatory mechanisms may have prevented pulmonary fibrosis, despite strong upregulation of pro-fibrotic genes.

Journal of Cystic Fibrosis (1)

Ramalho, A. S., S. Beck, et al. (2004). "Methods for RNA extraction, cDNA preparation and analysis of CFTR transcripts." Journal of Cystic Fibrosis **3**(Supplement 2): 11.

<http://www.sciencedirect.com/science/article/B6X2D-4CSG1X7-1/2/f47450de20d468e83c5bf97211802381>

The scope of this article is to outline some of the basic methods for good quality RNA preparation from mammalian tissues and cells (including epithelial cells). Additionally, we give an outline of common techniques of measuring CFTR gene expression such as quantitative and semi-quantitative reverse transcription (RT) PCR and ribonuclease protection assay (RPA). These methods are designed to detect low abundance transcripts, which apply to CFTR mRNA in most cell types and tissues.

Abiko, Y., M. Nishimura, et al. (2003). "Upregulated expression of human [beta] defensin-1 and -3 mRNA during differentiation of keratinocyte immortalized cell lines, HaCaT and PHK16-0b." Journal of Dermatological Science **31**(3): 225.

<http://www.sciencedirect.com/science/article/B6T87-4817HWB-1/2/8b2c2750dfb01bede7d627b022d47187>

Background: Human [beta]-defensins (hBDs) belong to a group of antimicrobial peptide that are expressed in the epithelial cells. Objective: The present study investigated mRNA expression levels of the [beta]-defensins, hBD-1, -2 and -3, in human keratinocytes during differentiation in vitro. Methods: Immortalized keratinocyte cell lines, HaCaT and PHK16-0b, were used in this study; in order to stimulate differentiation, the Ca²⁺ concentration in the growth media was increased from 0.3 to 1.8 mM. Results: Four days after the increase, the expression levels of hBD-1 and -3 were increased in both cell lines, followed by an increase in the mRNA levels of the differentiation markers, involucrin and keratin 10. No increased expression of hBD-2 was observed. Conclusion: The results indicate that keratinocyte differentiation may stimulate hBD-1 and -3 expression in stratified squamous epithelia.

Asahina, A., S. Kuwata, et al. (1996). "Study of aspartate at residue 9 of HLA-C molecules in Japanese patients with psoriasis vulgaris." Journal of Dermatological Science **13**(2): 125.

<http://www.sciencedirect.com/science/article/B6T87-3RHM5V1-11/2/27f5e711dab28ab9cb8919cf6e5f5fe0>

The frequency of aspartate at residue 9 (Asp-9) of HLA-C molecules was investigated among 75 Japanese patients with psoriasis vulgaris and 50 healthy controls. We developed a technique of polymerase chain reaction sequence-specific primer (PCR-SSP) amplification of genomic DNA for HLA-C alleles with a codon for Asp-9. The specificity of amplification was confirmed by direct sequencing of the amplified products and amplification from total RNA (RT-PCR). Asp-9 was positive in all individuals with Cw6 and/or Cw7, but negative in the others, indicating that Asp-9 was specific to Cw6 and Cw7 antigens in our subjects. The frequency of Asp-9 was significantly increased in the patient group (48% vs. 20%; $P < 0.0001$). Asp-9 is located on a [beta] sheet of [alpha] 1 domain of HLA-C molecule and influences the peptide binding of the C pocket of the groove together with Ala-73. Both Asp-9 and Ala-73 could contribute to the disease susceptibility to psoriasis vulgaris in the immune responses.

Goto, M., K. C. Sato-Matsumura, et al. (2004). "Tyrosinase gene analysis in Japanese patients with oculocutaneous albinism." Journal of Dermatological Science **35**(3): 215.

<http://www.sciencedirect.com/science/article/B6T87-4DBCK7Y-1/2/f8d147dbc3c750de14c79a7a9b773f30>

SummaryBackground:Oculocutaneous albinism (OCA) is a heterogeneous congenital disorder. Tyrosinase is a key enzyme in melanin biosynthesis, and tyrosinase gene mutations cause the OCA1 subtype.Objective:This study was intended evaluate the frequency and details of tyrosinase gene mutations in Japanese OCA patients.Patients and methods:We examined nine non-consanguineous OCA families, sequenced the tyrosinase gene of the patients and also confirmed a splicing site mutation using exon trapping system.Results:Tyrosinase gene mutations were identified in five out of nine OCA families (55%). IVS2-10delTT-7t-a was present in 3 out of 18 alleles in three families (16%), P310insC was present in three alleles in three families (16%) and R278X was found in three alleles (16%), including those in one heterozygous and one compound homozygous patient. G97V (290 G-T) was found in 1 out of 18 alleles, and we could not find G97V in the mutation database. We have added this mutation as 9th mutation of Japanese OCA1 patients. In 8 of 18 alleles, four families, no tyrosinase mutations were identified. They were presumed not to be OCA1, but other subtypes of OCA. Exon trapping system demonstrated IVS2-10delTT-7t-a mutation generated the abnormal splicing site, and inserted the codon 4 bases in mRNA level resulting in premature termination codon downstream.Conclusion:This study provided new information about OCA1 mutations, and highlights the requirement of broader detailed search to make precise diagnosis of OCA.

Ha, S.-J., J.-S. Kim, et al. (2003). "Analysis of genetic polymorphisms of steroid 5[alpha]-reductase type 1 and 2 genes in Korean men with androgenetic alopecia." Journal of Dermatological Science **31**(2): 135.

<http://www.sciencedirect.com/science/article/B6T87-47T8NWX-1/2/e0b16a253659aec2a16f240e719065a7>

Background: Genetic polymorphisms of steroid 5[alpha]-reductase have been studied in androgenetic alopecia in Caucasians, but the genes encoding the two isoenzymes were not associated with male pattern baldness. Genetic polymorphisms and ethnic variations have not been studied for Asians, although it is suggested that racial difference could exist and influence clinical phenotypes. **Objective:** The purpose of our study is to investigate the genetic polymorphisms of steroid 5[alpha]-reductase type 1 and 2 (SRD5A1 and SRD5A2) genes in Korean population, and to study the association of these polymorphisms with the development, clinical types (female or male pattern) and therapeutic response of androgenetic alopecia. **Methods:** Sixty-six patients with androgenetic alopecia and controls consisted of 92 healthy men

were included. Twenty-four patients were treated with finasteride for at least 6 months, and clinical responses were assessed by a simple classification. For type 1 isoenzyme, HinfI and NspI restriction fragment length polymorphisms (RFLPs) were detected using polymerase chain reaction method. For type 2 isoenzyme, RsaI RFLPs detected valine/leucine polymorphisms at codon 89, and MspI RFLPs detected alanine/threonine polymorphisms at codon 49. Results: We could not find any significant associations of the genetic polymorphisms of these two isoenzyme genes with androgenetic alopecia in Koreans ($P>0.05$). These polymorphisms were not associated with the clinical types of baldness or the response to finasteride ($P>0.05$). Conclusion: These results suggest that polymorphisms of SRD5A1 and SRD5A2 genes may not be directly associated with the development of baldness or generation of different clinical phenotypes.

Ichihashi, N. and Y. Kitajima (2000). "Loss of heterozygosity of adenomatous polyposis coli gene in cutaneous tumors as determined by using polymerase chain reaction and paraffin section preparations." Journal of Dermatological Science **22**(2): 102.

<http://www.sciencedirect.com/science/article/B6T87-3Y2N7S8-5/2/9e4efd49a842542dea6b20de55ca4249>

It has been suggested that an alteration in the adenomatous polyposis coli (APC) gene, which is a tumor suppressor gene, is one of the earlier events in carcinogenesis of some adenocarcinomas. We undertook this study to determine the prevalence of loss of heterozygosity (LOH) of the APC gene in several kinds of cutaneous tumors. Fifty-seven unrelated Japanese patients were examined for analysis of the APC gene. The 57 cases consisted of extramammary Paget's disease, squamous cell carcinoma (SCC), eccrine poroma and porocarcinoma, metastatic tumor of rectal adenocarcinoma and malignant melanoma. DNA was extracted from the tumor and normal portions dissected from the formalin-fixed paraffin-embedding sections and amplified with the use of the PCR. The amplified DNA was examined for LOH in the APC gene. Seven samples of 32 heterozygous persons of APC gene (three out of seven eccrine poromas, two eccrine porocarcinomas and two metastatic tumors of rectal adenocarcinoma) showed for LOH in the APC gene. None of the heterozygous samples from the extramammary Paget's disease (11), SCC (five) and melanoma (five) showed LOH. These results suggest that tumor or tumor suppressor genes, other than the APC gene, may be responsible for extramammary Paget's disease and SCC and that LOH involving APC may have some relevance to the formation and progression of eccrine tumors as in rectal tumors.

Kanekura, T., T. Kanzaki, et al. (1995). "p53 gene mutations in skin cancers with underlying disorders." Journal of Dermatological Science **9**(3): 209.

<http://www.sciencedirect.com/science/article/B6T87-4037RDS-8/2/70bfae5b1537ad734767b981a2619626>

Mutations in p53, a tumor suppressor gene, are one of the most common genetic lesions of human cancers. The relationship between p53 gene mutation and ultraviolet (UV) light has been demonstrated in skin cancers of sun-exposed sites. In this study, genomic DNA from 12 skin cancers was screened for mutations in exons 5 to 9 of this gene using the polymerase chain reaction -- single strand conformation polymorphism (PCR-SSCP) analysis followed by DNA sequencing. DNA samples were obtained from 8 basal cell carcinomas (BCCs): 1 from an organoid nevus, 1 from a patient with basal cell nevus syndrome, 1 from a patient with xeroderma pigmentosum, and 1 from a recurrent and 4 from primary sporadic lesions on actinic damaged skin, and from 4 squamous cell carcinomas (SCCs): 1 from a burn scar, 1 from a patient with epidermodysplasia verruciformis, and 2 from actinic keratosis. Mutation of the p53 gene was detected in only 1 case of SCC which had arisen from actinic keratosis. The mutation occurred at

codon 159 in exon S with a GCC to CCC base-pair substitution resulting in an amino acid change of alanine to proline. This mutation does not correspond to results of UV mutagenesis studies reported in the literature. Our findings imply that, although p53 gene mutation and UV exposure play an important role in the carcinogenesis of some skin cancers, they are not crucial, especially in skin cancers that develop from underlying skin disorders.

Kapur, S., M. A. O. H. Menke, et al. (2001). "Early mycosis fungoides: molecular analysis for its diagnosis and the absence of p53 gene mutations in cases with progression." Journal of Dermatological Science **26**(1): 36.

<http://www.sciencedirect.com/science/article/B6T87-42VM82Y-5/2/137767c4955ccc5f4dea19a2f4bc4c96>

The histological diagnosis of initial mycosis fungoides (MF) and the molecular mechanisms that are responsible for its progression and transformation to the more highly malignant variants of MF remain largely unknown. Because of the rare occurrence of these tumours, the need for snap frozen skin biopsy specimens and the difficulty to obtain suitable material for karyotypic and genotypic analysis, specific cytogenetic and molecular lesions have not yet been identified. In particular the role of known oncogenes and tumour suppressor genes, including the p53 gene, in the pathogenesis and clinical progression of MF has not been extensively investigated. The present study was carried out using the polymerase chain reaction (PCR) technique combined with temperature gradient gel electrophoresis (TGGE) to detect mutations of the p53 gene in 58 patients with MF. TGGE analysis was also used in combination with clonality analysis by means of T-cell receptor [gamma] (TCRG) gene rearrangement studies to distinguish parapsoriasis en plaque and initial MF from patch/plaque stage MF. More than 83% of the diagnoses of initial MF could be confirmed using PCR-TGGE analysis. However, although the sensitive TGGE analysis was used for all exons, p53 gene polymorphisms were found in 4 and p53 gene mutation in only 1 of 58 biopsy specimens. It appears unlikely that p53 gene mutations play a role in either the pathogenesis of parapsoriasis and initial MF or their progression to advanced stages of MF. However, TCRG gene rearrangement studies by means of TCR-TGGE analysis may be useful for distinguishing histologically discordant cases of initial MF.

Kubota, T., M. Dakeishi, et al. (2000). "Probable involvement of a germ-line mutation of an unknown mismatch repair gene in a Japanese Muir-Torre syndrome phenotype." Journal of Dermatological Science **23**(2): 117.

<http://www.sciencedirect.com/science/article/B6T87-408KCH0-6/2/2944f2cdedd732fdd8c630cd8b8006a9>

A combination of haplotype analysis and direct sequencing were conducted on Japanese Muir-Torre syndrome kindred. In the kindred, two females revealed a hereditary non-polyposis colon cancer (HNPCC) phenotype and one male had a sebaceous tumor in addition to a HNPCC phenotype. Haplotype analysis and direct sequencing failed to show involvement of the known mismatch repair genes, with the exception of MSH5, in this kindred. Analysis of large fragments (from 3.9 to 6.2 kb) covering the entire 25 kb MSH5 gene in the proband revealed the absence of gross changes in the promoter region and exons. The direct sequencing of the promoter region and all 25 exons failed to demonstrate any mutations in the coding regions except for a CA repeat polymorphism in intron 3 and a C/A polymorphism in intron 15. Taken together present results indicate that a novel and yet unknown mismatch repair gene is likely involved in the HNPCC in this kindred.

Matsuba, S., Y. Suga, et al. (2002). "Sulfhydryl oxidase (SOx) from mouse epidermis: molecular cloning, nucleotide sequence, and expression of recombinant protein in the cultured cells." Journal of Dermatological Science **30**(1): 50.

<http://www.sciencedirect.com/science/article/B6T87-46TG2X9-3/2/53e544f708b5cd01166e43e3502f4367>

Skin sulfhydryl oxidase (SOx) is an enzyme that catalyzes disulfide (S-S) cross-linking through the oxidation of sulfhydryl compounds in the skin. In this study, using the enzyme purified from rat seminal vesicle, we obtained peptide sequences for SOx by mass spectrometry. We then searched for SOx nucleotides corresponding highly to the rat peptide sequences by assembling murine-expressed sequence tags (ESTs) from the GeneBank database. The assembled mouse SOx cDNA has an open reading frame of 1704-bp nucleotides, translating into a size of 568 amino acids. The calculated molecular mass of the mouse SOx protein is 65 kDa. This mouse sequence can be amplified from total RNAs of various mouse tissue samples by reverse transcription polymerase chain reaction, especially highly amplified from those of the seminal vesicles and epidermis. The cDNA fragment was subsequently cloned into the mammalian expression vector (pTARGET-MSSOx), allowing us to express mouse recombinant SOx protein in cultured cells. When pTARGET-MSSOx was transfected, Western blot analysis using anti-SOx antiserum could detect a 65 kDa-band of recombinant SOx in both samples from the whole cell extract and the medium after the harvest of the HEK cells. In immunohistochemical analysis, the Pt-K2 cells, following the introduction of pTARGET-MSSOx, seemed to generate a SOx protein reactive to anti-SOx antiserum in the cells. Moreover, the indirect staining of the S-S bonds using N-(7-dimethylamino-4-methyl coumarinyl) maleimide (DACM), following the addition of N-ethylmaleimide and dithiothreitol, showed that the formation of S-S bridges almost matched the localization of SOx expression in the Pt-K2 cells after the transfection. In essence, we cloned skin SOx cDNA and characterized it as one of the S-S cross-linking enzymes. The SOx clone from mouse epidermis seems to be useful for investigating the potential function of the enzyme in the epidermis, especially for understanding the physiological role of SOx in the differentiation of keratinocytes.

Shimizu, M., A. Adachi, et al. (2004). "Detection of various types of human papillomavirus DNA, mainly belonging to the cutaneous-group, more frequently in normal tissue than in squamous cell carcinomas of the lip." Journal of Dermatological Science **36**(1): 33.

<http://www.sciencedirect.com/science/article/B6T87-4DBKGX9-3/2/f88341acbe6ede5eb41785ffc994682e>

SummaryBackground:Mucosal high-risk human papillomaviruses (HPVs), such as type 16, are detectable in oral cancers, especially of the oropharynx and tonsils, and there is evidence that they play a pathogenetic role in some cases. However, information is limited about their significance for cancers of the vermilion of the lip.**Objective:**To determine the detection rate, types and localization of HPVs in squamous cell carcinomas (SCCs) of the lip.**Methods:**Nested PCR for cutaneous HPVs, including epidermodysplasia verruciformis-related HPV (EV-HPV), and single PCR for mucosal HPVs, were conducted for a total of 27 SCCs and normal samples from 30 individuals. Tyramide-based in situ hybridization (ISH) was also applied.**Results:**Various types of HPVs were detected, particularly from normal individuals. Among the kinds of the HPV types detected in this study, half were found by PCR using a primer pair, which we newly designed. The prevalence of HPV was 5 out of 27 SCCs (ca. 18%) and 10 out of 30 normal individuals (ca. 33%). They were the entire cutaneous-group except for two, from one SCC and one normal individual.**Conclusion:**On the surface of the normal lip various types of mainly cutaneous-group HPVs may be present, but there does not appear to be any obvious association with SCCs

developing in this site.

Suga, T., M. Setoyama, et al. (1998). "Morphological, biochemical and molecular biological characteristics of a granulocyte colony-stimulating factor-producing human eccrine carcinoma cell line." Journal of Dermatological Science **16**(3): 200.

<http://www.sciencedirect.com/science/article/B6T87-3SBW2FT-4/2/407b7f9c7607a10c7b9fd2a084d4dfc8>

We describe here a newly established cell line from an eccrine carcinoma which produced an abundant amount of granulocyte colony-stimulating factor (G-CSF). An eccrine carcinoma of the scalp of a 69 year-old-Japanese female had metastasized to the pleura. Clinically, she had marked neutrophilia (up to 60000/mm³), and a high level of G-CSF (38.7 x 10³ pg/ml) was detected in the pleural effusion, as determined by enzyme-linked immunosorbent assay (ELISA). We established a cell line in vitro and maintained the cells in culture for 30 months in 90 subcultures. We investigated whether these tumor cells were able to produce G-CSF in culture and found that they were. We also found that the amount of G-CSF produced paralleled the rise in cell number (26.5 x 10³ pg/ml at confluency). When culture media were administered to rabbits (25 ml/rabbit), the amount of circulating neutrophils increased until the number was equal to or greater than that resulting from injection of recombinant human G-CSF (rhG-CSF)(75 [mu]g). This effect persisted for 7 days. When tumors were induced in SCID and nude mice by injecting cultured cells (1 x 10⁷ cells/mouse), the number of circulating neutrophils also correlated well with tumor size in these mice (200000/ mm³, 3 cm tumor). After tumor removal, the neutrophil number returned to normal within 30 days. G-CSF mRNA in cultured cells was detected by RT-PCR. Based on these results, it was confirmed that the marked neutrophilia observed in the patient was caused by the tumor-generated G-CSF. This is the first G-CSF-producing cell line developed from a cancer of the skin.

Yang, J.-M., K. Nam, et al. (1999). "Arginine in the beginning of the 1A rod domain of the keratin 10 gene is the hot spot for the mutation in epidermolytic hyperkeratosis." Journal of Dermatological Science **19**(2): 126.

<http://www.sciencedirect.com/science/article/B6T87-3VTHPY3-7/2/a8dabdb6f57b85657a7f6d6388bccbc2>

Keratin intermediate filaments are expressed in specific type I/type II pairs in the stage of differentiation of keratinocytes. The mutations in the keratin genes expressed in the epidermis are etiologically responsible for several epidermal genetic skin diseases, such as epidermolysis bullosa simplex, epidermolytic hyperkeratosis (EHK), ichthyosis bullosa of Siemens, palmoplantar keratoderma, pachyonychia congenita and white sponge nevus. The mutations of keratins 1/10 which are expressed in spinous and granular layers are confirmed to cause EHK. There are several trials to correlate between the clinical phenotypes and sites of mutations of the keratin genes. One of these is that EHK is divided into two groups: the palms and soles involvement (PS)

group and the non-palms and soles (NPS) group. So far the PS group had the mutations in the keratin 1 and the NPS group in keratin 10. Most of the mutations of the NPS group were reported in the beginning of the 1A rod domain and over 2/3 of the mutations in the 1A rod domain were the base pair substitution of arginine. Here we find two different mutations in two unrelated Korean kindreds classified as NPS group--R156C and R156H--in the 1A rod domain of keratin 10. Our results are compatible with the above classification and suggest that the arginine in the beginning of the 1A rod domain is the hot spot for the mutation of the keratin 10 gene.

Journal of Diabetes and its Complications (3)

Lindholm, E., M. Klannemark, et al. (2004). "Putative role of polymorphisms in UCP1-3 genes for diabetic nephropathy." Journal of Diabetes and its Complications **18**(2): 103.

<http://www.sciencedirect.com/science/article/B6T88-4CB7N0F-4/2/7b93e8fdd3904b190108cd0e67ce536e>

Increased production of reactive oxygen species (ROS) has been suggested as a cause of diabetic complications. Uncoupling proteins (UCPs) have been ascribed a role in reducing the formation of ROS, and genetic variation in genes encoding for UCPs could thus be putative candidate genes for diabetic nephropathy. To test this hypothesis we searched for association between the A->G (-3862) variant in UCP1, the insertion/deletion (I/D) polymorphism in exon 8 in UCP2, and the C->T (-55) polymorphism in UCP3 and diabetic nephropathy in 218 diabetic patients with normal urinary albumin excretion rate (AER), 216 with micro- or macroalbuminuria, and in 106 control subjects without a family history of diabetes. We did not find any association between the different polymorphisms and diabetic nephropathy, nor did we observe any difference in AER among carriers of different UCP1-3 genotypes. We could, however, confirm the reported association between BMI and the UCP3 -55 C->T polymorphism; patients carrying the T allele had higher BMI than patients homozygous for the C allele (26.4+/-4.2 vs. 25.3+/-4.3 kg/m²; P=.01). We conclude that studied polymorphisms in the UCP1-3 genes do not play a major role in the development of micro- or macroalbuminuria in Scandinavian diabetic patients.

Miura, J., Y. Uchigata, et al. (2004). "AGE down-regulation of monocyte RAGE expression and its association with diabetic complications in type 1 diabetes." Journal of Diabetes and its Complications **18**(1): 53.

<http://www.sciencedirect.com/science/article/B6T88-4C6JJDH-9/2/9a3e7cf4533e1f6fda8a68f31d79c425>

Advanced glycation end product (AGE) engagement of a cell surface receptor for AGE (RAGE) has been implicated in the development of diabetic complications. In this study, we determined the RAGE mRNA levels in monocytes from type 1 diabetic patients and analyzed their relationship with diabetic vascular complications. Quantitative reverse transcription-polymerase chain reaction (RT-PCR) analysis revealed that the monocyte expression of RAGE mRNA was significantly lower in patients with retinopathy than in those without retinopathy and was also significantly down-regulated in patients with nephropathy in comparison with those without nephropathy. Experiments with monocyte-enriched cultures revealed that RAGE mRNA and protein levels were down-regulated by the exposure to glyceraldehyde-derived AGE--the recently

identified high-affinity RAGE ligand. Accordingly, we then assayed for the serum levels of glyceraldehyde-derived AGE as well as those of carboxymethyllysine (CML)--the known RAGE ligand and related them to the monocyte levels of RAGE mRNA. This screen revealed a negative correlation between the two parameters. The results thus suggest that the decrease in monocyte RAGE expression can be at least partly accounted for by the ligand engagement and may be a factor contributing to the development of diabetic vascular complications.

Murata, M., N. Ohta, et al. (2002). "Selective pericyte degeneration in the retinal capillaries of galactose-fed dogs results from apoptosis linked to aldose reductase-catalyzed galactitol accumulation." Journal of Diabetes and its Complications **16**(5): 363.

<http://www.sciencedirect.com/science/article/B6T88-46K20KJ-B/2/6d117bb4eb487153fee7b8c99f5bbf40>

Galactose-fed dogs develop retinal capillary changes similar to diabetic retinopathy with pericyte degeneration as the initial lesion. This is followed by the formation of microaneurysms, hemorrhages, and some areas of acellularity. To investigate the mechanisms for selective pericyte degeneration, retinal capillary pericytes and endothelial cells isolated from beagle dog retina were cultured for 2 weeks in Dulbecco's modified Eagle's medium (DMEM) containing 50 mM -galactose. Apoptosis was detected in pericytes but not endothelial cells by in situ terminal deoxynucleotidyl transferase (TdT)-mediated biotin-dUTP nick end labelling (TUNEL) staining and the DNA fragmentation assay on agarose gel electrophoresis. This apoptosis was prevented by the addition of the aldose reductase inhibitor AL 1576 to the culture medium containing galactose. Apoptosis was not observed when pericytes were similarly cultured in control DMEM medium. These data support the premise that the selective degeneration of retinal capillary pericytes observed in galactose-fed dogs is linked to increased aldose reductase activity in these cells.

Journal of Gastrointestinal Surgery (8)

Brabender, J., R. V. Lord, et al. (2001). "Upregulation of ornithine decarboxylase mRNA expression in barrett's esophagus and barrett's-associated adenocarcinoma." Journal of Gastrointestinal Surgery **5**(2): 174.

<http://www.sciencedirect.com/science/article/B6W8T-44423W2-8C/2/21da48e0129a76674995a5ed0c207631>

The Barrett's multistage process is characterized histopathologically by progression from Barrett's intestinal metaplasia to Barrett's esophagus with dysplasia and ultimately adenocarcinoma. Understanding the cellular and molecular events in this multistage process may contribute to improved diagnosis and treatment. Ornithine decarboxylase (ODC) is the first enzyme in the biosynthesis of polyamines. Elevated ODC activity has been found to be associated with progression during Barrett's esophagus, but the regulation of ODC gene expression in the development of Barrett's-associated adenocarcinoma has not been reported. The aim of this study was to assess the prevalence and timing of ODC mRNA expression in the Barrett's metaplasia-dysplasia-adenocarcinoma sequence. ODC mRNA expression levels, relative to the stably expressed internal reference gene [beta]-actin, were measured using a quantitative

reverse transcription-polymerase chain reaction (RT-PCR) method (ABI 7700 Sequence Detector System) in 104 specimens from 19 patients with Barrett's esophagus without carcinoma and 22 patients with Barrett's-associated adenocarcinoma. The median ODC mRNA expression levels were significantly increased in Barrett's esophagus tissues compared to matched normal tissues in patients without adenocarcinoma of the esophagus ($P = 0.002$; Wilcoxon test). A significant progressive increase in ODC mRNA expression was detectable through the stages of the metaplasia-dysplasia-carcinoma sequence in patients with Barrett's-associated adenocarcinoma ($r = 0.719$; $P \leq 0.001$; Spearman's rho test). These findings show that upregulation of ODC mRNA expression is an early event in the development and progression of Barrett's-associated adenocarcinoma of the esophagus, and they suggest that high ODC mRNA expression levels may be a clinically useful biomarker for the detection of occult adenocarcinoma.

Brabender, J., R. V. Lord, et al. (2004). "Role of retinoid X receptor mRNA expression in Barrett's esophagus." Journal of Gastrointestinal Surgery 8(4): 413.

<http://www.sciencedirect.com/science/article/B6W8T-4C88SFD-G/2/81dc8b2ff35a56b7903f0e5755be1621>

The Barrett's multistage process is characterized histopathologically by progression from Barrett's intestinal metaplasia to Barrett's esophagus with dysplasia and ultimately adenocarcinoma. Understanding of the molecular alterations in this multistage process may contribute to improved diagnosis and treatment. Retinoid X receptors (RXR) play an important role in regulating the morphogenesis, development, growth, and differentiation of cells. Alterations in RXR expression have been observed in a variety of solid tumors; however, the role in Barrett's esophagus disease has yet to be determined. The aim of this study was to assess the prevalence and timing of RXR messenger RNA expression in the Barrett's metaplasia-dysplasia-adenocarcinoma sequence and to investigate its role in the development and progression of this disease. We analyzed the mRNA expression of all three RXR subtypes (RXR- α , RXR- β , and RXR- γ) by using a quantitative real-time reverse transcription-polymerase chain reaction method in 108 specimens from 19 patients with Barrett's esophagus without carcinoma (BE group), 20 patients with Barrett's-associated adenocarcinoma (EA group), and a control group of 10 patients without evidence of gastroesophageal reflux disease (CG). RXR- α mRNA expression was significantly decreased ($P = 0.01$; Wilcoxon test) and adenocarcinoma tissues ($P = 0.018$, Mann-Whitney test). RXR- α and RXR- β mRNA expression was significantly associated in normal squamous esophagus tissues ($r^2 = 0.49$; $P = 0.63$; $r^2 = 0.68$; $P = 0.001$). There were significant differences in RXR- α ($P = 0.011$) and RXR- β ($P = 0.005$) mRNA expression in histopathologically normal squamous esophagus tissues in patients with cancer and the control group without evidence of gastroesophageal reflux disease. These findings suggest that alterations in the mRNA expression of all three RXR subtypes are frequent events in the development and progression of Barrett's esophagus and associated adenocarcinoma, that RXR mRNA expression levels may be useful biomarkers for this disease, and that a widespread "field-effect" is present in the normal esophagus of patients with esophageal adenocarcinoma.

Brabender, J., R. V. Lord, et al. (2002). "Glutathione S-Transferase-Pi Expression Is Downregulated in Patients With Barrett's Esophagus and Esophageal Adenocarcinoma." Journal of Gastrointestinal Surgery 6(3): 359.

<http://www.sciencedirect.com/science/article/B6W8T-45TY7F9-M/2/e92c1f7f89afa373e80860a4bf872a28>

The glutathione S-transferases (GSTs) are a family of enzymes that play an important role in the prevention of cancer by detoxifying numerous potentially carcinogenic compounds. GSTs

conjugate reduced glutathione to a variety of electrophilic and hydrophobic compounds, converting them into more soluble, more easily excretable compounds. Decreased glutathione S-transferase-pi (GSTPI) enzyme activity has been reported in Barrett's esophagus, and an inverse correlation was demonstrated between GST enzyme activity and tumor incidence in the gastrointestinal tract, but the role of GSTPI messengerRNA (mRNA) expression in Barrett's esophagus and associated adenocarcinomas is uncertain. The purpose of this study was to investigate the role of GSTPI mRNA and protein expression in the development and progression of the Barrett's metaplasia-dysplasia-adenocarcinoma sequence, and to investigate the potential of GSTPI quantitation as a biomarker in the clinical management of this disease. GSTPI mRNA expression levels, in relation to the housekeeping gene [beta]-actin, were analyzed using a quantitative real-time reverse transcription-polymerase chain reaction method (TaqMan) in 111 specimens from 19 patients with Barrett's esophagus without carcinoma (BE group), 21 patients with Barrett's-associated adenocarcinoma (EA group), and a control group of 10 patients without evidence of Barrett's esophagus or chronic gastroesophageal reflux disease. GSTPI mRNA expression was detectable in all 111 samples investigated. Analyzed according to histopathologic group, the median GSTPI mRNA expression was highest in normal squamous esophagus epithelium, intermediate in Barrett's esophagus, and lowest in adenocarcinoma tissues ($P = 0.001$) or the EA group ($P = 0.023$). GSTPI expression levels in adenocarcinoma tissues were decreased compared to matching normal esophagus tissues from the patients with adenocarcinoma ($P = 0.011$). Furthermore, GSTPI mRNA expression values were significantly different between metaplastic, dysplastic, and adenocarcinoma tissues ($P = 0.026$). GSTPI expression levels were also significantly lower in histologically normal squamous esophagus tissues from patients with cancer (EA group) compared to both normal esophagus tissues from patients without cancer (BE group; $P = 0.007$) and normal esophagus tissues from the control group with no esophageal abnormality ($P = 0.002$). GSTPI protein expression was generally highest in the basal layer of normal squamous esophagus epithelium and lowest in adenocarcinoma cells, with Barrett's cells showing intermediate staining intensity. Our results show that downregulation of GSTPI expression is an early event in the development of Barrett's esophagus and esophageal adenocarcinoma. Loss of GSTPI expression may have an important role in the development and progression of this disease. (2002;6:359-367.)

Glatzle, J., C. M. Leutenegger, et al. (2004). "Mesenteric lymph collected during peritonitis or sepsis potentially inhibits gastric motility in rats." *Journal of Gastrointestinal Surgery* 8(6): 645.

<http://www.sciencedirect.com/science/article/B6W8T-4D9VBRY-2/2/bf3c80631fd02e3b6908430376508d8d>

Gastrointestinal motility is strongly inhibited during peritonitis or sepsis and proinflammatory cytokines released into mesenteric lymph during an acute gastrointestinal insult mediate systemic responses. We investigated whether mesenteric lymph collected during peritonitis or sepsis inhibits gastric motility and gastric emptying. Mesenteric lymph was collected for 12 hours from three experimental groups: vehicle (saline, 1 ml, intraperitoneally [ip], control lymph), peritonitis (0.5% acetic acid, 1ml, ip, peritonitis lymph), and sepsis (lipopolysaccharide [LPS], 5 mg/kg, 1 ml, ip, sepsis lymph). Gastric motility and gastric emptying were measured in recipient rats in response to lymph injections into the jugular vein. Quantitative polymerase chain reaction (PCR) for tumor necrosis factor [alpha] (TNF[alpha]) gene expression in the jejunum and in lymph cells were measured during sepsis. Mesenteric lymph flow significantly increased during peritonitis or sepsis (lymph flow [ml] per 60 minutes; control 2.45 [plus-or-minus sign] 0.04; peritonitis 2.67 [plus-or-minus sign] 0.07; sepsis 3.25 [plus-or-minus sign] 0.1, $p < 0.05$, 1.89 [plus-or-minus sign] 1.31 minutes; peritonitis lymph: -0.56 [plus-or-minus sign] 0.06 cm H₂O, 9.9 [plus-or-minus sign] 0.9 minutes; sepsis lymph: -0.51 [plus-or-minus sign] 0.05 cm H₂O, 6.9 [plus-or-minus sign] 0.6 minutes; $p < 0.001$ vs. basal; 12 hours: 24.7 [plus-or-minus sign] 16.8, not significant [NS]; 24 hours: 7.0 [plus-or-minus sign] 3.4, NS). In conclusion, mediators in mesenteric lymph, possibly cytokines, may be responsible for the inhibition of gastric motility during peritonitis or sepsis.

Because the composition of mesenteric lymph probably reflects the interstitial fluid of the gut wall, monitoring visceral lymph might be an extremely beneficial tool to determine mediators released during impaired gut wall function.

Kuramochi, H., D. Vallbohmer, et al. (2004). "Quantitative, tissue-specific analysis of cyclooxygenase gene expression in the pathogenesis of Barrett's adenocarcinoma." Journal of Gastrointestinal Surgery 8(8): 1007.

<http://www.sciencedirect.com/science/article/B6W8T-4DYV0NT-J/2/6168ee832eaf88fdad25a84924abe1a>

Cyclooxygenase (Cox-2) is implicated in the pathogenesis of many cancers including esophageal adenocarcinoma (EAC), whereas the role of the isoform Cox-1 in carcinogenesis is not well understood. To further elucidate the role of these factors in the development of EAC, we measured the gene expressions (mRNA levels) of Cox-2 and Cox-1 by real-time quantitative polymerase chain reaction (QRT-PCR) in tissues from normal esophagus with and without erosive gastroesophageal reflux disease (GERD), Barrett's esophagus (BE), dysplasia, adenocarcinoma, and in healthy gastric antrum. All tissues were purified by laser capture microdissection from endoscopic or surgical resection specimens. Median Cox-2 gene expression did not differ significantly among the esophageal control groups but was elevated 5-fold in BE, 8-fold in dysplasia and 16-fold in EAC compared to normal esophageal controls with no erosive GERD. Erosive GERD tissue had slightly higher median Cox-2 expression but Cox-2 expression in normal antrum was much higher than that in a normal esophagus, close to that of dysplasia. In contrast to that of Cox-2, Cox-1 expression was significantly decreased in all neoplastic tissues compared to normal controls. Cox-1 and Cox-2 expression varied over a wide range in the neoplastic tissues but over a relatively narrow range in the esophageal normal tissues. The occurrence of substantial alterations in Cox-1 and Cox-2 expression at the BE stage indicates that these are early events in the development of EAC. These results confirm the important role of Cox-2 amplification in the pathogenesis of esophageal adenocarcinoma, but the unexpected down-regulation of Cox-1 raises questions about its role in carcinogenesis.

Lord, R. V. N., D. Salonga, et al. (2000). "Telomerase reverse transcriptase expression is increased early in the Barrett's metaplasia, dysplasia, adenocarcinoma sequence." Journal of Gastrointestinal Surgery 4(2): 135.

<http://www.sciencedirect.com/science/article/B6W8T-4442JP3-FS/2/c796073fd269f8a183e99a8cb5aeb0c8>

Barrett's esophagus is a multistage polyclonal disease that is associated with the development of adenocarcinoma of the esophagus and esophagogastric junction. Telomerase activation is associated with cellular immortality and carcinogenesis, and increased expression of the telomerase reverse transcriptase catalytic subunit (hTERT) has been used for the early detection of malignant diseases. To identify biomarkers associated with each stage of the Barrett's process, relative mRNA expression levels of hTERT were measured using a quantitative reverse transcription--polymerase chain reaction method (ABI 7700 Sequence Detector (TaqMan system)) in Barrett's intestinal metaplasia (n = 14), Barrett's dysplasia (n = 10), Barrett's adenocarcinoma (n = 14), and matching normal squamous esophagus tissues (n = 32). hTERT expression was significantly increased at all stages of Barrett's esophagus, including the intestinal metaplasia stage, compared to normal tissues from patients without cancer (intestinal metaplasia vs. normal esophagus, P = 0.001; adenocarcinoma, P = 0.007; all Mann-Whitney U test). hTERT expression levels were significantly higher in adenocarcinoma tissues than in intestinal metaplasia tissues (P = 0.003), and were higher in dysplasia compared with intestinal metaplasia

tissues ($P = 0.056$). hTERT levels were also significantly higher in histologically normal squamous esophagus tissues from cancer patients than in normal esophagus tissues from patients with no cancer ($P = 0.013$). Very high expression levels ([hTERT x 100: [beta]-actin] > 20) were found only in patients with cancer. These findings suggest that telomerase activation is an important early event in the development of Barrett's esophagus and esophageal adenocarcinoma, that very high telomerase levels may be a clinically useful biomarker for the detection of occult adenocarcinoma, and that a widespread cancer "field" effect is present in the esophagus of patients with Barrett's cancer.

Okami, J., K. Dono, et al. (2003). "Patterns of regional lymph node involvement in intrahepatic cholangiocarcinoma of the left lobe." Journal of Gastrointestinal Surgery 7(7): 850.

<http://www.sciencedirect.com/science/article/B6W8T-49V9HDY-6/2/ae0c6806ff7a2ec5163b8778e94ee103>

Lymph node involvement is an important prognostic factor in intrahepatic cholangiocarcinoma. Besides the nodes in the hepatoduodenal ligament, recent studies have suggested that the nodes around the cardiac portion of the stomach or along the gastric lesser curvature can be affected when the primary tumor is located in the left hepatic lobe. However, the distribution of metastatic nodes has not been well described in this disease. Thirteen patients with intrahepatic cholangiocarcinoma in the left hepatic lobe were enrolled in this study. Lymphatic mapping was performed by means of both histologic examination and reverse transcriptase-polymerase chain reaction assays. Nodal involvement around the cardiac portion of the stomach or along the lesser gastric curvature (left pathway) was found in 7 (54%) of 13 patients by histologic examination or reverse transcriptase-polymerase chain reaction, whereas positive nodes in the hepatoduodenal ligament (right pathway) were found in 6 (46%) of 13 patients. Two patients (15%) had positive nodes only in the left pathway. Therefore, for a more accurate clinical staging of intrahepatic cholangiocarcinoma in the hepatic left lobe, lymph nodes around the cardiac portion of the stomach and along the lesser gastric curvature should be examined in addition to nodes in the hepatoduodenal ligament.

Otto, C., J. Kauczok, et al. (2002). "Mechanisms of Tolerance Induction After Rat Liver Transplantation: Intrahepatic CD4+ T Cells Produce Different Cytokines During Rejection and Tolerance in Response to Stimulation." Journal of Gastrointestinal Surgery 6(3): 455.

<http://www.sciencedirect.com/science/article/B6W8T-45TY7F9-12/2/ba96303a02810beedb2dc9f4ccd44fbb>

Increasing evidence supports the existence of regulatory T cells that may inhibit the allogeneic immune response after transplantation by secreting regulatory cytokines. To determine whether rat liver tolerance is associated with intrahepatic regulatory T cells secreting a characteristic cytokine profile, we analyzed the cytokine production of freshly isolated intrahepatic CD4+ T cells at different times postoperatively by semiquantitative reverse transcription-polymerase chain reaction and by enzyme-linked immunosorbent assay before and after in vitro stimulation. Orthotopic arterialized liver transplantation was performed in two allogeneic rat strain combinations, one with fatal acute rejection (DA-to-LEW) and one with long-lasting tolerance (LEW-to-DA) without immunosuppression despite a complete major histocompatibility complex mismatch (spontaneous liver tolerance). Liver allografts of both groups showed continuously increasing cellular infiltration between day 3 and day 7 after transplantation. In this inflammatory situation, very low levels of interleukin-13 were detectable directly after cell isolation, as well as after in vitro stimulation. However, after 30 days, intrahepatic CD4+T cells in the tolerance group were then able to express elevated messenger RNA levels of the anti-inflammatory cytokine

interleukin-13 in response to stimulation. This result indicates the presence of an intra-graft Th2-like CD4⁺ T cell population, which may have a regulatory function in the induction of liver tolerance. (2002;6:455-463.)

Journal of Hepatology (38)

Baba, S., H. Fujii, et al. (2004). "Commitment of bone marrow cells to hepatic stellate cells in mouse." Journal of Hepatology **40**(2): 255.

<http://www.sciencedirect.com/science/article/B6W7C-4B26K5D-1/2/1f992d1a1bcb26a7412077e4cd8c3e8d>

Background/Aims: Recently, several cells found within the liver have been reported to derive from bone marrow (BM). This study sought to examine the commitment of BM cells to hepatic stellate cell (HSC) lineage in mouse liver. **Methods:** We transplanted BM cells from green fluorescent protein (GFP) transgenic mice into age-matched C57BL/J mice. Hepatic nonparenchymal cells were isolated from the livers of BM-transplanted mice using density gradient centrifugation with Nycodenz. The expression of lineage markers by the isolated cells was evaluated by RT-PCR and immunostaining. We then examined the histology of liver tissues obtained from BM-transplanted mice with and without carbon tetrachloride-induced injury. **Results:** GFP-expressing cells with intracytoplasmic lipid droplets comprised 33.4 $\pm$ 2.3% of the cells isolated by density gradient centrifugation. These cells expressed the HSC lineage markers, such as desmin and glial fibrillary acidic protein (GFAP), by both RT-PCR and immunostaining. During a 7-day culture, GFP-positive cells began to express α -smooth muscle actin, a marker of activated HSC. In the liver of BM-transplanted mice, GFP-positive nonparenchymal cells expressed GFAP and extended their process around hepatocytes. Upon liver injury, these cells also co-expressed desmin and α -smooth muscle actin. **Conclusions:** Nonparenchymal cells, derived from transplanted BM, acquired HSC characteristics in both quiescent and activated states.

Bedoucha, M., E. Atzpodien, et al. (2001). "Diabetic KKAY mice exhibit increased hepatic PPAR[gamma]1 gene expression and develop hepatic steatosis upon chronic treatment with antidiabetic thiazolidinediones." Journal of Hepatology **35**(1): 17.

<http://www.sciencedirect.com/science/article/B6W7C-43BXNDF-4/2/29fa0987458b34931cfb68aad084f0d0>

Background/Aims: Peroxisome proliferator-activated receptor-[gamma], which is involved in the regulation of lipid homeostasis, is upregulated in the liver of obese and diabetic mice, but the biological consequences of this induction are largely unknown. This study was aimed at further characterizing this upregulation and exploring the downstream biological effects of specific activators on hepatic lipid metabolism. **Methods:** Hepatic expression of peroxisome proliferator-activated receptor-[gamma]1 and [gamma]2 mRNA and protein was analyzed by real-time polymerase chain reaction and Western immunoblotting in KKAY mice and ob/ob mice. KKAY mice were treated with thiazolidinediones, and hepatic triglyceride content and lipid distribution were analyzed biochemically and by histopathology. **Results:** KKAY mice exhibited a marked increase in hepatic peroxisome proliferator-activated receptor-[gamma]1 mRNA and protein levels, whereas the [gamma]2 isoform was upregulated in ob/ob mice. Treatment of KKAY mice

with troglitazone or rosiglitazone resulted in severe microvesicular periportal steatosis, whereas lean control mice did not develop any pathological liver changes. Hepatic triglyceride levels, however, were not altered by the treatment. Conclusions: In mice with obesity-associated upregulated hepatic peroxisome proliferator-activated receptor- γ expression, thiazolidinediones may produce hepatic steatosis. Under pathophysiological conditions, such as non-insulin-dependent diabetes, the liver may thus become sensitized towards peroxisome proliferator-activated receptor- γ -activating drugs.

Bernal, W., P. Donaldson, et al. (1998). "Tumor necrosis factor genomic polymorphism and outcome of acetaminophen (paracetamol)-induced acute liver failure." *Journal of Hepatology* **29**(1): 53.

<http://www.sciencedirect.com/science/article/B6W7C-44FMMDV-9G/2/8613a0b1aa82c9edc9a087017d703fc9>

Background/Aims: High levels of tumor necrosis factor- α are associated with an increased risk of severe encephalopathy in acute liver failure, and experimental studies suggest that tumor necrosis factor- α plays a role in the development of acetaminophen (paracetamol)-induced liver injury and associated multiple organ failure. Inter-individual variations in the production of tumor necrosis factor- α have been linked to genomic polymorphisms within the tumor necrosis factor- α locus. This study examined whether specific tumor necrosis factor polymorphisms are associated with variations in the severity of clinical features in acetaminophen-induced acute liver failure. **Methods:** Genotypes at the -308 tumor necrosis factor A and tumor necrosis factor B Nco1 polymorphic sites were determined in 97 patients with severe acetaminophen-induced hepatotoxicity and 109 controls, using polymerase chain reaction and restriction fragment length polymorphism. The relationship between liver injury, multiple organ failure and encephalopathy, determined retrospectively from clinical notes and genotype, was examined. **Results:** No significant association was found between either tumor necrosis factor A or B genotype and parameters for multiple organ failure or liver injury. The tumor necrosis factor B1B1 genotype was significantly under-represented in those patients developing severe encephalopathy ($p = 0.03$) and a multivariate logistic regression analysis confirmed the influence of tumor necrosis factor B genotype (p_{DRB1^*03} , which is closely linked to the TNFB locus). **Conclusions:** The development of acute liver failure is unlikely to be primarily sepsis driven. However, the apparent protective effect of the tumor necrosis factor B1B1 genotype on the development of severe encephalopathy may be related to the effects of this genotype on tumor necrosis factor- α production in sepsis.

Bernal, W., M. Moloney, et al. (1999). "Association of tumor necrosis factor polymorphism with primary sclerosing cholangitis." *Journal of Hepatology* **30**(2): 237.

<http://www.sciencedirect.com/science/article/B6W7C-4406K4G-18/2/67fad28433468d9302953dcf3a736db4>

Background/Aims: Primary sclerosing cholangitis is associated with the HLA haplotypes A1-B8-DRB3*0101-DRB1*0301-DQA1*0501-DQB1*0201 and DRB3*0101-DRB1*1301-DQA1*0103-DQB1*0603. However, the interpretation of these genetic associations is controversial. One explanation may be that HLA-encoded susceptibility is due to other genes carried on these haplotypes such as the HLA class III tumor necrosis factor genes. The aim of the study was to investigate tumor necrosis factor genetics in a large series of well-defined patients. **Methods:** One hundred and ten HLA genotyped patients and 126 control subjects were studied by polymerase chain reaction genotyping for 3 different tumor necrosis factor gene polymorphisms: -308, -238 and an Nco1 restriction fragment length polymorphism in the lymphotoxin α gene. **Results:** Overall, 58% of patients had the TNF2 allele, compared with 29% of controls, $p = 0.0001$. No

association was found with either of the other tumor necrosis factor polymorphisms examined. TNF2 was significantly increased in the presence of B8 and DRB3*0101 only, and was independent of DRB1*0301 (pcB8 and TNF2 were stronger than the associations with any of the HLA class II alleles examined. Conclusion: HLA-encoded genetic susceptibility to primary sclerosing cholangitis may be determined by polymorphism within the HLA class III region, in particular with the TNF2 allele.

Brind, A., J. Jiang, et al. (1997). "Evidence for selection of hepatitis B mutants after liver transplantation through peripheral blood mononuclear cell infection." Journal of Hepatology **26**(2): 228.

<http://www.sciencedirect.com/science/article/B6W7C-44FMP1S-WB/2/4901d2d9a29e243b1464970b6ca06c33>

Background/Aims: Despite anti-HBs immunoglobulin therapy, hepatitis B virus (HBV) infection recurs in a high proportion of patients transplanted for HBsAg positive and serum HBV DNA negative chronic liver disease. The contribution of HBV genetic variability to disease recurrence has not been yet thoroughly addressed. We have therefore undertaken a detailed comparison of preS/S and preC/C sequences in two selected patients with recurrence of HBsAg and HBV DNA after transplantation. Methods: PreS/S and preC/C regions were amplified by PCR from the serum, peripheral blood mononuclear cell (PBMC) and liver tissues of two patients transplanted for end stage HBV-related cirrhosis. Samples were taken both pre- and post-transplantation. HBV-sequences from four to nine clones were determined and compared. Results: A mixing of different HBV DNA molecules was observed within and between serum, liver and PBMC samples. Sequences from both patients showed mutations in the preC region which abolished HBeAg secretion, and in the preS2 initiation codon which prevented preS2 envelope protein production. In addition, for both patients, deletions in the preS2 domains (3 and 21 base pairs) led to the expression of modified preS1 envelope protein. For one patient, the predominant HBs protein sequence found in the PBMC before transplantation showed four specific mutations. One of these mutations was in the "a" determinant (codon 144, asparagine to glycine change) of the major envelope protein. These mutations were not detected, as predominant mutations, in the liver and serum pre-orthotopic liver transplant samples. In contrast, after liver transplantation, this was the major form identified in serum, liver and PBMC. Conclusions: Our results have shown the selection of different HBV DNA molecules in liver and mononuclear cells. In addition, they provide direct evidence for the role of PBMC in the infection of liver grafts and support the hypothesis that infection of PBMC might lead to selection of HBV variants which would escape immune therapy. Finally, we provide in vivo evidence for reinfection of the liver by HBV particles lacking preS2 envelope protein expression.

Cassanelli, S., E. Pignatti, et al. (2001). "Frequency and biochemical expression of C282Y/H63D hemochromatosis (HFE) gene mutations in the healthy adult population in Italy." Journal of Hepatology **34**(4): 523.

<http://www.sciencedirect.com/science/article/B6W7C-42NH34J-6/2/6bb712051a2bd979d431b9c6297f1848>

Background/Aims: The actual prevalence of the main hemochromatosis (HFE) mutations in the Italian adult population and their phenotypic expression have not yet been established. This information is key to advocate a mass-screening program. Methods: Two thousand one hundred adults were tested for the C282Y/H63D HFE gene mutations by an automated genotyping assay as well as transferrin saturation (TS) and serum ferritin levels. Results: No homozygotes for the C282Y mutation were found. Heterozygosity for the C282Y mutation was 3.1%, while heterozygosity and homozygosity for the H63D mutation were 21.5% and 2.5%, respectively. TS

was significantly higher in C282Y heterozygotes and H63D homozygotes as compared to wild-type individuals (P). Interestingly, of the HFE wild-type subjects 5.9% had a TS value above the 45% threshold. Conclusions: This study shows that (i) the predicted prevalence for C282Y homozygosity in Italy is 1:3900; (ii) the C282Y/H63D wild-type population has an increased baseline of iron parameters possibly due to genetic factors not linked to the C282Y/H63D mutations; (iii) since in the latter population the actual tissue iron burden cannot be assessed, phenotypic (TS) screening in Italy is not recommended until the true prevalence of all mutations in the HFE gene and in other hemochromatosis genes will be established.

Colombatto, P., M. R. Brunetto, et al. (1999). "High prevalence of G1 and G2 TT-virus infection in subjects with high and low blood exposure risk: identification of G4 isolates in Italy." Journal of Hepatology **31**(6): 990.

<http://www.sciencedirect.com/science/article/B6W7C-437YWM4-8N2/5237ca463b74116f9d0e36fd305088cb>

Background/Aims: A non-enveloped single-stranded DNA virus (TTV) was detected in Japanese patients with fulminant hepatitis (47%) and chronic liver disease of unknown etiology (46%) more frequently than in blood donors (12%). Subsequent studies, however, questioned the association of TTV with liver disease. We further investigated the role of this novel virus in liver diseases. Methods: We tested 106 patients and 102 blood donors for TTV by polymerase chain reaction using conserved region primers. Results: TTV DNA was found in 19 of 102 volunteer blood donors (18.6%) and in 27 of 106 patients with liver disease (25.5%): 10 of 28 chronic hepatitis B (35.7%), 9 of 28 chronic hepatitis C (32.1%) and 8 of 50 (16%) cryptogenic liver disease patients. Previous interferon treatment was not associated with a significantly lower prevalence of TTV infection. TTV prevalence was higher in patients with blood exposure (42.8%, 6/14) than in patients without risk factors (21.4%, 18/84). Four of five patients (80%) with HBV familial infection and without blood exposure were also TTV positive. Partial nucleotide sequences from 3 Italian isolates diverged more than 30% from the 2 prototype genotypes G1 and G2 and were 88% homologous to the recently described genotype G4. Conclusions: G1 and G2 TTV are common in Italy and in the USA in liver disease patients and in blood donors. The prevalence is high in patients with blood exposure but also in subjects without risk factors; other routes of transmission should therefore be considered.

Doughty, A. L., D. M. Painter, et al. (2000). "Post-transplant quasispecies pattern remains stable over time in patients with recurrent cholestatic hepatitis due to hepatitis C virus." Journal of Hepatology **32**(1): 126.

<http://www.sciencedirect.com/science/article/B6W7C-436FVDT-53/2/76b838311dc7a942c8b80dc9581f18eb>

Background/Aims: Several studies have shown that cholestatic recurrent hepatitis is associated with very high HCV RNA loads in liver transplant recipients. The aim of this study was to investigate whether a correlation exists between cholestatic hepatitis posttransplant and the population of viral quasispecies. Methods: One hundred and nine serial sera samples were tested from 15 recurrent HCV patients. Four of these patients showed severe cholestatic recurrent hepatitis, 11 patients demonstrated non-cholestatic recurrent hepatitis post-transplant. Quasispecies were detected by RT-PCR amplification of the HVR1 followed by single-stranded conformational polymorphism analysis. Results: Forty-one samples from four cholestatic patients were tested. All four patients showed very stable quasispecies patterns post-transplant. One cholestatic patient also showed a stable quasispecies band pattern following retransplantation, again associated with severe cholestatic hepatitis. Sixty-eight samples were tested from the 11

non-cholestatic patients. In contrast, these patients showed significantly more quasispecies bands than the cholestatic patients. The noncholestatic patients also displayed fluctuating band patterns post-transplant. Serial samples were tested after retransplantation in one non-cholestatic patient, with a fluctuating pattern again seen. There was a negative correlation between the HCV RNA load in serum and the number of quasispecies bands. Conclusions: Stable hepatitis C viral quasispecies associated with persistently high viral load in post-transplant cholestatic hepatitis suggest that viral escape from immune pressures may play a role in the pathogenesis of this condition.

Dumoulin, F. L., C. Reichel, et al. (1997). "Semiquantitation of intrahepatic MDR3 mRNA levels by reverse transcription/competitive polymerase chain reaction." *Journal of Hepatology* **26**(4): 852.

<http://www.sciencedirect.com/science/article/B6W7C-437YSV7-1S/2/96c313c3c8eb02430d9f41c00eefc105>

Background/Aims: Knockout mice lacking *mdr2*, the murine analogue of human MDR3 P-glycoprotein, develop chronic non-suppurative cholangitis. Recently, a deficiency in MDR3 messenger RNA (mRNA) has been reported in a subtype of progressive familial intrahepatic cholestasis. Thus, reduced MDR3 gene expression could be involved in human cholestatic liver diseases. Methods: We developed a sensitive and specific reverse transcription/competitive polymerase chain reaction for the semiquantitation of intrahepatic MDR3 mRNA levels. Using this method we determined the MDR3 mRNA levels in 52 liver specimens from primary biliary cirrhosis (n=11), chronic hepatitis B (n=5), chronic hepatitis C (n=14), non-cholestatic cirrhosis (n=9) and controls (n=13). Results: MDR3 mRNA was detected in all specimens with some variation in mRNA levels. No significant differences in the mean MDR3 mRNA levels were present between the groups studied, including normal controls. Conclusions: We found no evidence for deficient or severely reduced intrahepatic MDR3 mRNA in primary biliary cirrhosis, nor were mRNA levels altered significantly by virus-induced inflammation or by cirrhosis. The reverse transcription/competitive polymerase chain reaction assay described here should be a useful tool in the semiquantitative study of MDR3 mRNA levels in small tissue specimens.

Fanning, P. A., J. R. Jonsson, et al. (2000). "Detection of male DNA in the liver of female patients with primary biliary cirrhosis." *Journal of Hepatology* **33**(5): 690.

<http://www.sciencedirect.com/science/article/B6W7C-436FX5D-GW/2/f987e66f0a0522691dd090bc3a6b0d71>

Background/Aims: Primary biliary cirrhosis is a chronic cholestatic liver disease characterized by progressive inflammatory destruction of bile ducts, with eventual hepatic fibrosis and cirrhosis. Since primary biliary cirrhosis affects predominantly middle-aged women and has pathological similarities to hepatic graft-versus-host-disease, we investigated whether fetal cell microchimerism might be involved in the development of this disease. Methods: The presence of Y-chromosome-specific sequences was analyzed by polymerase chain reaction using peripheral blood mononuclear cells from women with primary biliary cirrhosis (n=18) and healthy (control) women (n=18), and by in situ hybridization of liver biopsy sections from women with primary biliary cirrhosis (n=19) and women with chronic hepatitis C or alcoholic liver disease (n=20). Results: Male cells were detected in liver biopsy specimens of 8 of 19 patients (42%) with primary biliary cirrhosis. Y-chromosome-containing cells were not seen in any of the liver biopsy specimens from women with chronic hepatitis C or alcoholic liver disease. Male cells were detected in peripheral blood mononuclear cells from one healthy control at a level of 1 male cell per 106 female cells, but were not detected in peripheral blood mononuclear cells of women with primary biliary cirrhosis. Conclusions: The presence of male cells in the liver of women with

primary biliary cirrhosis raises the possibility that fetal cell microchimerism may be involved in the pathogenesis of this chronic liver disease.

Fiume, L., G. D. Stefano, et al. (1997). "Hepatotropic conjugate of adenine arabinoside monophosphate with lactosaminated poly--lysine: Synthesis of the carrier and pharmacological properties of the conjugate." Journal of Hepatology **26**(2): 253.

<http://www.sciencedirect.com/science/article/B6W7C-44FMP1S-WF/2/101480370e9ff4aac1a0979f2865aee3>

Background/Aims: The hepatotropic conjugate of adenine arabinoside monophosphate with lactosaminated poly--lysine (-Poly(Lys)) must have a high solubility in order to be injected in a small volume compatible with the intramuscular route. In this paper the molecular weights of Poly(Lys) which allowed the synthesis of conjugates with the properties of high solubility and limited loss by the kidney were determined and a procedure for obtaining Poly(Lys) preparations with the required range of polymerization has been described. **Methods:** Conjugates were prepared using Poly(Lys) of different molecular weights obtained by the procedure described here or purchased from a commercial source. Their solubility and renal loss in mice was determined. **Results:** Poly(Lys) with molecular weights ranging from 45000 and 65000 Da guarantees high solubility and low renal elimination of the conjugates. Conjugate preparations with these properties, intramuscularly administered to woodchuck hepatitis virus-infected woodchucks for 37 days at a daily dose of 5.8 mg/kg exerted a strong antiviral activity. These preparations were devoid of acute toxicity in rat and caused no toxic effects when injected intramuscularly daily for 28 days at a dose ten times higher than that active in woodchucks. **Conclusions:** The results support the possibility of a clinical use of -Poly(Lys) to obtain liver targeting of adenine arabinoside monophosphate for the treatment of chronic hepatitis B virus infection.

Fujikawa, T., T. Hirose, et al. (2003). "Purification of adult hepatic progenitor cells using green fluorescent protein (GFP)-transgenic mice and fluorescence-activated cell sorting." Journal of Hepatology **39**(2): 162.

<http://www.sciencedirect.com/science/article/B6W7C-48W2GWT-2/2/4edf902a203cabbc9bf293dd1ba80fd7>

Background/Aims: Recent advances in stem cell research have revealed that hepatic stem/progenitor cells may play an important role in liver development and regeneration. However, a lack of detectable definitive markers in viable cells has hindered their primary culture from adult livers. **Methods:** Enzymatically dissociated liver cells from green fluorescent protein (GFP)-transgenic mice, which express GFP highly in liver endodermal cells, were sorted by GFP expression using a fluorescence-activated cell sorter. Sorted cells were characterized, and also low-density cultured for extended periods to determine their proliferation and clonal differentiation capacities. **Results:** When CD45-TER119- side-scatterlow GFP^{high} cells were sorted, [alpha]-fetoprotein-positive immature endoderm-characterized cells, having high growth potential, were present in this population. Clonal analysis and electron microscopic evaluation revealed that each single cell of this population could differentiate not only into hepatocytes, but also into biliary epithelial cells, showing their bilineage differentiation activity. When surface markers were analyzed, they were positive for Integrin-[alpha]6 and -[beta]1, but negative for c-Kit and Thy1.1. **Conclusions:** Combination of GFP-transgenic mice and fluorescence-activated cell sorting enabled purification of hepatic progenitor cells from adult mouse liver. Further analysis of this population may lead to purification of their human correspondence that would be an ideal cell-source candidate for regenerative medicine.

Ghez, D., E. Nicand, et al. (2001). "Allogenic bone marrow transplantation with a donor presenting with an acute hepatitis A." Journal of Hepatology **34**(4): 625.

<http://www.sciencedirect.com/science/article/B6W7C-42NH34J-R/2/a909ff7f1d5a3d1090c5c63d17e8854d>

We report the unique occurrence of an allogenic bone marrow transplantation performed as the donor was suffering from an acute hepatitis A. The bone marrow was contaminated at the time of collection, as demonstrated by hepatitis A virus (HAV) RNA detected by RT-PCR. Hepatitis A virus infection in such a situation could have resulted in a severe liver disease in the recipient. However, although we could demonstrate that the recipient had been infected, he did not develop a symptomatic hepatitis A but only minor disturbances of liver function tests between days 35 and 55. Both the postponement of the transplantation and the use of intravenous polyvalent immunoglobulins have probably played a key role in decreasing the viral load and allowing a rapid clearance of the virus. A possible role of the grafted immune system might also be envisaged, as suggested by the de novo synthesis of IgM in the recipient.

Grassi, G., G. Pozzato, et al. (1995). "Quantitative analysis of hepatitis C virus RNA in liver biopsies by competitive reverse transcription and polymerase chain reaction." Journal of Hepatology **23**(4): 403.

<http://www.sciencedirect.com/science/article/B6W7C-44FMM3R-5X/2/c0848b0defc2c19dd9bfb547a6714fe0>

Background/Aims: The determination of HCV-RNA concentration in liver samples is likely to provide interesting insights for the study of disease progression and for evaluation of the efficacy of anti-viral therapy. **Methods:** a procedure was developed for the precise quantification of HCV-RNA in liver biopsies, based on the competitive reverse transcription-polymerase chain reaction technology. This competitive assay consists of the co-amplification of the target RNA with known amounts of a competitor RNA molecule containing the same sequence as the target plus an insertion in the middle, allowing resolution of the two amplification products by gel electrophoresis. **Results:** The amounts of HCV-genomic-RNA and [beta]-actin mRNA (the latter being used as an internal standard to overcome the problem of reproducibility of quantitative RNA extraction) were evaluated in liver biopsies of 15 patients affected by hepatitis C virus-positive chronic liver disease at the time of diagnosis. All the patients underwent [alpha]-interferon therapy for 6 months and were subsequently followed for at least 1 further year after the end of treatment. Viral RNA concentration (which ranged from 2 to 2.7×10^5 HCV-RNA molecules per 10^6 [beta]-actin molecules) directly correlated with the efficacy of treatment, indicating that low levels of viral replication in the liver are associated with a poor response to therapy. **Conclusions:** This study suggests that the determination of viral load in the liver is an important prognostic tool for the prediction of the efficacy of [alpha]-interferon therapy.

Iavarone, M., J.-B. Trabut, et al. (2003). "Characterisation of hepatitis B virus X protein mutants in tumour and non-tumour liver cells using laser capture microdissection." Journal of Hepatology **39**(2): 253.

<http://www.sciencedirect.com/science/article/B6W7C-48TK824-6/2/cd121ba4565b1e163fd36426cd90e4e6>

Background/Aims: The analysis of hepatitis B virus (HBV) X protein genetic variability and is

correlation with liver disease severity have only been addressed, so far, on whole liver extracts. We have studied, therefore, the HBV X protein (HBx) gene sequence in morphologically well-characterised tumour and non-tumour liver cells from patients with HBV-related hepatocellular carcinoma. Methods: Using laser capture microdissection (LCM), we picked up six to eight groups of tumour and non-tumour hepatocytes in serial frozen sections from six patients. After global DNA preamplification followed by HBx-specific polymerase chain reaction, the HBx gene was sequenced in each group of microdissected cells. We also validated the quantification of HBV-DNA in microdissected hepatocytes using HBV Amplicor(R). Results: Heterogeneous mutations in HBx gene were found in distinct cirrhotic nodules and tumour areas from the same patient. Mutations at aa 127, 130 and 131 were frequently detected but there was no distinct point mutation profile between tumour and non-tumour samples. In contrast, deletions in HBx gene, which were found in five/six patients, were more frequent in tumour-derived sequences (6/18) than in non-tumour-derived sequences (1/20). Conclusions: We have shown that LCM provides a direct insight of intrahepatic HBV infection. Using this technique, we demonstrated the persistence of distinct HBx encoding sequences in clonally expanding cells, thus supporting the hypothesis that HBx deletions may be implicated in liver carcinogenesis.

Ikeda, H., M. Takasu, et al. (1999). "Infection with an unenveloped DNA virus (TTV) in patients with acute or chronic liver disease of unknown etiology and in those positive for hepatitis C virus RNA." *Journal of Hepatology* **30**(2): 205.

<http://www.sciencedirect.com/science/article/B6W7C-4406K4G-13/2/b8f963051ddc0d0324b6135ac0bc3665>

Background/Aims: An unenveloped single-stranded DNA virus (TTV) has been reported in association with elevated transaminase levels in patients with posttransfusion hepatitis and in those with acute or chronic liver disease of unknown etiology. To further evaluate the association of TTV with liver disease, TTV DNA was searched for in patients with acute or chronic liver disease of various etiologies. Methods: TTV DNA was determined by polymerase chain reaction with hemi-nested primers in 64 patients with acute or chronic liver disease of unknown etiology and in 100 with acute or chronic liver disease positive for antibody to hepatitis C virus (HCV) as well as HCV RNA. Results: TTV DNA was detected in two of the seven (29%) patients with acute hepatitis of unknown etiology, but in none of the four patients with acute HCV-associated hepatitis. It was detected in 27 of the 57 (47%) patients with chronic liver disease of unknown etiology at a frequency significantly higher (p Conclusions: Based on the obtained results, TTV has a role in the development of acute and chronic liver disease of unknown etiology.

Kang-Park, S., N. Dray-Charier, et al. (1998). "Role for PKC [alpha] and PKC [epsiv] in down-regulation of CFTR mRNA in a human epithelial liver cell line." *Journal of Hepatology* **28**(2): 250.

<http://www.sciencedirect.com/science/article/B6W7C-43S17MD-2X/2/bb055edd504415efac1e7b01728e2436>

Background/Aims: In the liver, intrahepatic biliary cells are the sole site of expression of the cystic fibrosis transmembrane conductance regulator, the product of the cystic fibrosis gene. We examined the regulation of cystic fibrosis transmembrane conductance regulator gene expression by protein kinase C in the recently characterized human liver epithelial BC1 cell line which expresses, at early confluence, both biliary (cystic fibrosis transmembrane conductance regulator, cytokeratin 19) and hepatocytic (albumin) specific markers. Methods: Expression of the cystic fibrosis transmembrane conductance regulator was examined at the mRNA level by Northern blot, reverse transcription-polymerase chain reaction and nuclear run-on assays and at the protein level by Western blotting. The functionality of this protein was tested by measurement of

chloride efflux. Protein kinase C isotype expression and cytosol-to-membrane translocation were analysed by Western blotting. Results: 1) Phorbol ester down-regulated cystic fibrosis transmembrane conductance regulator mRNA expression in a time- and dose-dependent manner through a post-transcriptional mechanism with concomitant inhibition of stimulated chloride efflux. 2) Phorbol ester also activated protein kinase C as indicated by the cytosol-to-membrane translocation of both protein kinase C [alpha] and [epsilon] the two major protein kinase C isotypes expressed by BC1 cells. 3) Further, maximal down-regulation of the cystic fibrosis transmembrane conductance regulator mRNA by the phorbol ester was inhibited by H7 and by GF 109203X, two known protein kinase C inhibitors. Conclusions: These findings provide the first evidence for phorbol ester-induced down-regulation of cystic fibrosis transmembrane conductance regulator mRNA expression in a human liver epithelial cell line and point to a role for the classical protein kinase C [alpha] and the novel protein kinase C [epsilon] in this process.

Llorente, L., Y. Richaud-Patin, et al. (1996). "Cytokine gene expression in cirrhotic and non-cirrhotic human liver." *Journal of Hepatology* **24**(5): 555.

<http://www.sciencedirect.com/science/article/B6W7C-44FMMWN-GF/2/7a42c28608d1dbdb15ea894f35385607>

Background/Aims: In order to explore the role of cytokines in the pathogenesis of liver cirrhosis, we analyzed their gene expression in hepatic biopsies from patients with alcoholic liver cirrhosis, post-hepatitis C liver cirrhosis, and with idiopathic portal hypertension without cirrhosis. Methods: We assessed the gene expression of interleukins 1[beta], 2, 6, 8, and 10, as well as of tumor necrosis factor-[alpha], transforming growth factor-[beta] and interferon-[gamma] by a quantitative polymerase chain reaction. Results: We found high levels of transforming growth factor-[beta] in post-hepatitis C liver cirrhosis, high to moderate in alcoholic liver cirrhosis and low in non-cirrhotic specimens. Expression of interleukin-10, tumor necrosis factor-[alpha], and interferon-[gamma] genes was detected in most post-hepatitis C liver cirrhosis, but not in idiopathic portal hypertension or alcoholic liver cirrhosis biopsies. The interleukin1-[beta], 6 and 8 gene expression was significantly lower in alcoholic liver cirrhosis compared to post-hepatitis C liver cirrhosis, but higher compared to idiopathic portal hypertension specimens. Thus, post-hepatitis C liver cirrhosis samples showed a high degree of cytokine gene expression, whereas in alcoholic liver cirrhosis it tended to be moderate, and restricted to some cytokines (transforming growth factor-[beta], interleukin-1, 6 and 8, but not interleukin-10, tumor necrosis factor-[alpha] or interferon-[gamma]). In contrast, most non-cirrhotic specimens showed a restricted and low cytokine gene expression. Conclusions: These data suggest that transforming growth factor-[beta] may have an important role in liver fibrosis and inflammation. Interleukin-1[beta], 6, 8, tumor necrosis factor-[alpha] and interferon-[gamma], appear to participate in the pathogenesis of the mild to severe inflammatory phenomena seen in alcoholic and post-hepatitis C liver cirrhosis, respectively. Our data suggest that tumor necrosis factor-[alpha] does not participate in the hepatocellular damage of alcoholic liver cirrhosis, and indicate that neither interferon-[gamma] nor interleukin-10, at least at the levels observed in post-hepatitis C liver cirrhosis, are able to counteract the fibrotic/inflammatory process seen in this condition.

Minami, H., K. Tada, et al. (2000). "Enhancement of retrovirus-mediated gene transfer to rat liver in vivo by infusion of hepatocyte growth factor and triiodothyronine." *Journal of Hepatology* **33**(2): 183.

<http://www.sciencedirect.com/science/article/B6W7C-436FWWH-DX/2/8eb22ea1763a0b3b0268e8e974deef28>

Background/Aims: Gene transfer using recombinant Moloney murine leukemia viruses (rMoMuLV) requires mitosis of the target cell. Previously, we and others have used partial

hepatectomy for induction of hepatocellular proliferation for gene transfer to the liver in vivo by exsanguineous perfusion with rMoMuLV. We hypothesized that induction of hepatocellular proliferation by combined administration of two hepatocellular mitogens, hepatocyte growth factor (HGF) and triiodothyronine (T3), should permit rMoMuLV-mediated gene transfer into liver without invasive approaches. **Methods:** HGF (1 mg/kg) was perfused continuously into the portal vein of Wistar male rats and T3 (2 mg/kg) was injected subcutaneously. Twenty-four hours after injecting HGF and T3, the state of proliferation of hepatocytes was estimated from the incorporation of 5'-bromo-2'-deoxy-uridine (BrdU). The amphotropic retroviral receptor (Ram-1) expression of liver was evaluated at different time points after injecting HGF and T3 by means of Northern blotting using Ram-1 cDNA probe. In order to evaluate the role of hormone treatment on gene transfer, the liver was perfused exsanguineously with rMoMuLV 24 h after injection with hormones. **Results:** Rats treated with a combination of HGF and T3 expressed BrdU and [beta]-galactosidase in 8.3% and 0.7% of hepatocytes, respectively. On the other hand, there was near absence of gene transfer in untreated rats perfused with rMoMuLV. Twenty-four hours after the initial manipulation, abundant expression of Ram-1 mRNA was observed in rat hepatocytes treated with HGF plus T3. **Conclusions:** Stimulation of hepatocellular mitosis and upregulation of Ram-1 expression by HGF and T3 augment retrovirus-mediated gene transfer into hepatocytes.

Moaven, L. D., S. A. Locarnini, et al. (1997). "Hepatitis G virus and fulminant hepatic failure: evidence for transfusion-related infection." *Journal of Hepatology* **27**(4): 613.

<http://www.sciencedirect.com/science/article/B6W7C-436FV7M-3G/2/4bd283149a68f4d8d99f609b2f3f969d>

Background/Aims: In the majority of cases of fulminant "viral" hepatitis in Australia, no known aetiological agent can be isolated. We have examined the possible role of the recently discovered hepatitis G virus (HGV) in such cases. **Methods:** An HGV specific reverse transcription polymerase chain reaction (RT-PCR) was performed on pre- and post-liver transplant serum from 14 patients who were referred for transplantation at our unit between 1989 and 1995 for unexplained fulminant hepatic failure. Eleven patients successfully underwent transplantation and three died while waiting for a suitable donor organ. Hepatitis viruses A-E were excluded by standard serological and PCR based testing. HGV RT-PCR was also performed on 21 other, randomly selected, liver transplant recipients ("controls"). **Results:** The 14 fulminant cases were HGV RT-PCR negative prior to transplantation while five of 21 controls were positive. Post-transplant, eight of the 11 fulminant patients were found to be HGV RT-PCR positive and the same five controls remained HGV RT-PCR positive. In three of the eight fulminant patients the HGV infection resolved. **Conclusions:** Our data indicate that HGV infection is unlikely to be responsible for fulminant hepatitis and that it is probably acquired from blood and/or blood products during the transplantation process. Furthermore, long-term carriage of HGV post-transplant is not associated with clinically apparent liver disease.

Morimoto, O., H. Nagano, et al. (2003). "Diagnosis of intrahepatic metastasis and multicentric carcinogenesis by microsatellite loss of heterozygosity in patients with multiple and recurrent hepatocellular carcinomas." *Journal of Hepatology* **39**(2): 215.

<http://www.sciencedirect.com/science/article/B6W7C-48TK824-1/2/9b1697554f3212b8bea9eb5dde671f3b>

Background/Aims: The prognosis of hepatocellular carcinoma (HCC) is poor because of frequent intrahepatic metastasis (IM) or multicentric carcinogenesis (MC). We compared the effectiveness of loss of heterozygosity (LOH) analysis in the diagnosis of these two forms with that of histopathological diagnosis. **Methods:** Using LOH analysis of 15 specific DNA microsatellite loci,

tumor clonality was assessed in 37 cases. Results: LOH was observed in 30% of seven solitary tumors. According to these results, the selected threshold to diagnose MC was a difference in the LOH status at more than 30% of the analyzed loci, when comparing two samples in the same liver. In nine multiple HCCs, identical genetic and histopathological diagnoses were found in four (IM: 2, MC: 2). Of 21 recurrent tumors, 19 showed LOH for at least one marker. IM and MC were genetically diagnosed in five and ten patients, respectively. Genetic and histopathological diagnoses were identical in ten of 19 patients (IM: 5, MC: 5). Five genetic MC were histopathologically diagnosed as IM (3) and 'undetermined' (2). Conclusions: Genetic diagnosis by LOH analysis may be more strict and specific than histopathological diagnosis in the differential diagnosis of IM and MC.

Muller, T., B. van de Sluis, et al. (2003). "The canine copper toxicosis gene MURR1 does not cause non-Wilsonian hepatic copper toxicosis." *Journal of Hepatology* **38**(2): 164.

<http://www.sciencedirect.com/science/article/B6W7C-4753J8J-2/2/bb4c402e4d33ce7c8d529a2180b01ee1>

Background: Non-Wilsonian hepatic copper toxicosis includes Indian childhood cirrhosis (ICC), endemic Tyrolean infantile cirrhosis (ETIC) and the non-Indian disease known as idiopathic copper toxicosis (ICT). These entities resemble the hepatic copper overload observed in livers of Bedlington terriers with respect to their clinical presentation and biochemical and histological findings. We recently cloned the gene causing copper toxicosis in Bedlington terriers, MURR1, as well as the orthologous human gene on chromosome 2p13-p16. Aim: To study the human orthologue of the canine copper toxicosis gene as a candidate gene for ICC, ETIC, and ICT. Methods: We sequenced the exons and the intron-exon boundaries of the human MURR1 gene in 12 patients with classical ICC, one patient with ETIC, and 10 patients with ICT to see whether these patients display any mutations in the human orthologue of the canine copper toxicosis gene. Results: No mutations in the MURR1 gene, including the intron-exon boundaries, were identified in a total of 23 patients with non-Wilsonian hepatic copper toxicosis. Conclusions: Our results demonstrate that copper toxicosis in Bedlington terriers is not an animal model for the non-Wilsonian hepatic copper toxicosis described in this study.

Nakano, T., Y.-M. Park, et al. (1999). "TT virus infection among blood donors and patients with non-B, non-C liver diseases in Korea." *Journal of Hepatology* **30**(3): 389.

<http://www.sciencedirect.com/science/article/B6W7C-4407456-5K/2/a12c8e12be6e7e85350ce13f246a7241>

Background/Aims: A novel virus, designated the TT virus (TTV), was isolated from the serum of a patient with posttransfusion hepatitis of unknown etiology, in Japan. Subsequently, TTV was suggested to be a causative agent in a proportion of cases with cryptogenic hepatitis in Japan. This study aimed to elucidate the significance of TTV infection in cases with cryptogenic liver disease in Korea, a neighbor of Japan. Methods: The prevalence of TTV infection was studied in 120 patients with liver diseases, including 85 patients diagnosed as having non-B, non-C liver diseases. As controls, 220 blood donors were also examined. TTV DNA was detected by polymerase chain reaction, and the sequence was analyzed by phylogenetic analysis. Results: Fourteen (14.0%) of 100 accepted blood donors, 23 (19.2%) of 120 rejected blood donors, and 15 (17.6%) of 85 patients with non-B, non-C liver diseases were positive for TTV DNA. The prevalences of TTV infection among these groups were not significantly different. Phylogenetic analysis suggested the existence of four major genotypes of TTV. The proportions of each genotype among patients with non-B, non-C liver diseases were not different from those among accepted blood donors. Conclusions: TTV exists in Korea, but the prevalence among patients with

non-B, non-C liver diseases was almost the same as that among blood donors. TTV may not be the main causative agent of cryptogenic liver disease in Korea. The relationship between non-B, non-C liver diseases and TTV genotype remains unclear, although TTV can be classified into four genotypes.

Noguchi, O., N. Enomoto, et al. (1996). "Gene expressions of c-met and hepatocyte growth factor in chronic liver disease and hepatocellular carcinoma." Journal of Hepatology 24(3): 286.

<http://www.sciencedirect.com/science/article/B6W7C-44FMMN4-CX/2/776d3466bcd67827212affedf340f0>

Background/Aims: The roles of c-met proto-oncogene and hepatocyte growth factor in human livers have not been shown. **Methods:** Gene expressions of both c-met and hepatocyte growth factor were quantified in livers with chronic active hepatitis and in cirrhotic livers with hepatocellular carcinoma as well as in normal controls, using competitive reverse transcription polymerase chain reaction. **Results:** C-met expression was significantly increased in chronic active hepatitis compared with control livers, and c-met expression in chronic active hepatitis correlated with serum alanine aminotransferase levels. Hepatocyte growth factor expression was increased in some patients with chronic active hepatitis compared with controls, and there was a significant correlation between c-met expression and hepatocyte growth factor expression. On the other hand, in hepatocellular carcinoma tissues, c-met expression was increased in some cases, while that in the surrounding non-carcinomatous tissues was similar to normal controls. Hepatocyte growth factor expression was not detected in the hepatocellular carcinoma tissues and was low in the surrounding non-carcinomatous tissues. **Conclusions:** These findings suggest that hepatocyte growth factor may be involved in the regeneration of hepatocytes via paracrine mechanism in chronic active hepatitis, while the regulation of c-met expression in hepatocellular carcinoma tissues may be independent of hepatocyte growth factor stimulation.

Peck-Radosavljevic, M., J. Pidlich, et al. (1998). "Preoperative TNM-classification is a better prognostic indicator for recurrence of hepatocellular carcinoma after liver transplantation than albumin mRNA in peripheral blood." Journal of Hepatology 28(3): 497.

<http://www.sciencedirect.com/science/article/B6W7C-44FMKNF-1M/2/66d608c117602c5e5d32f7dc48040dad>

Background/Aims: Survival after orthotopic liver transplantation for hepatocellular carcinoma is limited by a high rate of tumor recurrence. A polymerase chain reaction assay based on the detection of albumin mRNA expression in peripheral blood for detection of hematogenous micrometastasis of hepatocellular carcinoma has been described, which may help to select candidates for orthotopic liver transplantation. **Methods:** The prognostic value of a highly sensitive nested reverse transcription-polymerase chain reaction assay was evaluated in comparison with the TNM-classification of the International Union against Cancer in a population of liver transplant candidates. **Results:** Eighty patients with liver disease and 42 control patients were evaluated. Six of 21 patients with hepatocellular carcinoma and 11 of 59 patients with other diseases of the liver were positive for albumin reverse transcription-polymerase chain reaction, making this assay an indicator of ongoing liver damage without absolute specificity for hepatocellular carcinoma. Twelve patients with hepatoma were followed after liver transplantation and seven of those patients had a tumor recurrence within 12 months. Six of these patients with recurrence had International Union against Cancer stage IV A tumors preoperatively, while only one of them was positive for albumin reverse transcription-polymerase chain reaction before transplantation. Only one patient with a stage I to III tumor had a recurrence within 12 months. **Conclusions:** Detection of albumin mRNA in peripheral blood by reverse transcription-polymerase chain reaction seems

to be an unreliable marker for assessing hematogenous spread of hepatocellular carcinoma. With International Union against Cancer stage IV A being a much better predictor of tumor recurrence, the practical value of albumin mRNA reverse transcription-polymerase chain reaction for patient selection in liver transplant candidates seems to be very limited.

Pina, S., M. Buti, et al. (2000). "HEV identified in serum from humans with acute hepatitis and in sewage of animal origin in Spain." *Journal of Hepatology* **33**(5): 826.

<http://www.sciencedirect.com/science/article/B6W7C-436FX5D-HJ2/7fc8e501a128c1f11d235ac6d8add1c6>

Background/Aims: Hepatitis E virus (HEV) is an enterically transmitted pathogen that appears sporadically in non-endemic countries. We studied HEV as a causal agent of acute hepatitis cases in the Spanish population, and the role of pigs as an animal reservoir. **Methods:** The presence of HEV-RNA was analysed by nested polymerase chain reaction in 37 serum samples from patients with acute viral hepatitis, 48 porcine serum samples, 6 pig faecal samples and 12 slaughterhouse sewage samples. Presence of antibodies was also tested in porcine sera. **Results:** HEV-RNA was found in 3 human serum samples from patients presenting IgG anti-HEV antibodies. Nucleotide sequence analysis identified 2 strains with 93.4% identity, phylogenetically most closely related to the Greece1 isolate, and more closely related to North American and other European strains than to those from endemic regions. HEV-RNA was also detected in slaughterhouse sewage mainly from pigs, presenting 92-94% nucleotide similarity compared to the strains detected in the human sera. Twenty-five per cent of the pigs tested presented IgG anti-HEV antibodies. **Conclusions:** These data suggest that the HEV could be more widespread than previously thought, and present new evidence of the close relationship between HEV strains detected in pigs and those from acute hepatitis patients.

Punia, P., P. Cane, et al. (2004). "Quantitation of hepatitis B lamivudine resistant mutants by real-time amplification refractory mutation system PCR." *Journal of Hepatology* **40**(6): 986.

<http://www.sciencedirect.com/science/article/B6W7C-4BSWHF1-1/2/f8f6480b8d8adf28d4203cdc3905f017>

Background/Aims: Lamivudine is an antiviral drug that is used to treat hepatitis B virus (HBV) infection. Long-term therapy does not completely suppress viral replication, and resistant mutants emerge. Resistance is mediated by changes in the tyrosine-methionine-aspartate-aspartate (YMDD) motif in the catalytic site of the HBV polymerase gene. We describe a method to detect and quantify mutant viral populations using amplification refractory mutation system (ARMS) PCR. **Methods:** We developed a real-time ARMS-PCR to detect point mutations in the polymerase gene. Using real-time PCR (LightCycler) with a Resonance probe, PCRs were performed using clones of the HBV polymerase gene containing the different YMDD mutations. Dilution series of the templates were made and tested against each of the primer pairs. This method was applied to quantify mutant virus in patient serum samples. **Results:** As little as 0.01% mutant DNA in 10⁵-10⁹ copies wild-type DNA were detected. The method is more sensitive than amplicon sequencing, which is the current method of mutant determination in the YMDD motif. **Conclusions:** This study demonstrates a rapid, highly sensitive and reproducible method of quantifying mutant HBV virus in lamivudine treated patients. It can be used to monitor patients before and during lamivudine therapy.

Saito, T., K. Shinozaki, et al. (2004). "Lack of evidence for reovirus infection in tissues from patients with biliary atresia and congenital dilatation of the bile duct." Journal of Hepatology **40**(2): 203.

<http://www.sciencedirect.com/science/article/B6W7C-4B54X84-3/2/50b419e222b118621638cb1a07e94f7d>

Background/Aims: To clarify the association between the reovirus infection of the hepatobiliary tree and the development of infantile obstructive cholangiopathy (IOC) including biliary atresia (BA) and congenital dilatation of the bile duct (CBD). **Methods:** We designed reovirus common primers for nested RT-PCR based on the L3 gene segment. The spectrum and the sensitivity of common primers were evaluated with purified reoviral RNAs and reovirus mixed with stool samples. Then, nested RT-PCRs were performed with hepatobiliary and fecal samples obtained from patients with BA, CBD, and control diseases. Additionally, electron microscopy of stool samples was performed. **Results:** The L3 common primers could amplify cDNAs synthesized from RNAs of three prototypes of reovirus, and detect as much as 5.0×10^3 plaque forming unit of serotype 3 Dearing strain in 100 mg of fecal samples. However, no amplification product was detected in 136 hepatobiliary tissues taken from 67 patients including 26 BAs and 28 CBDs, or in 65 fecal samples obtained from 15 patients including 10 BAs and 1 CBD. Additionally, viral particles were not found in any stool specimens by the electron microscope. **Conclusions:** These data do not suggest that reoviruses play a major role in the etiology of IOC or BA.

Shimizu, Y., M. Minemura, et al. (2003). "Preferential accumulation of CD103+ T cells in human livers; its association with extrathymic T cells." Journal of Hepatology **39**(6): 918.

<http://www.sciencedirect.com/science/article/B6W7C-49KS3D7-2/2/12fab404a39726e0729693863ac028df>

Background/Aims: CD103, a mucosal integrin $[\alpha]E[\beta]7$, binds to E-cadherin expressed on hepatocytes and bile duct epithelium in the liver. Although CD103+ T cells are enriched in intestinal intraepithelial lymphocytes, the localization of those cells in the liver is unknown. **Methods:** We investigated whether CD103+ cells are present in human livers, and how they are associated with the intrahepatic development of T cells by flow cytometry and immunohistochemistry. **Results:** Human livers contain significantly ($P < 0.05$) more CD4+ and CD8+ T cells (25.7 ± 13.5 and $27.1 \pm 19.3\%$, respectively) than peripheral blood lymphocytes. Moreover, CD103+ cells in the liver, but not in peripheral blood, contained T cells with intermediate expression level of T cell receptor $[\alpha][\beta]$. Those cells consist of mostly CD4+ and CD4-CD8- cells, and expressed low level of CD56 and interleukin-2 receptor beta chain in most of the population. These characteristics are distinct from natural killer T cells, which have been thought to be extrathymic T cells in human livers. Moreover, intrahepatic CD103+ cells expressed mRNA for recombination-activating gene-1, -2 and pre T cell receptor- α detected by reverse transcription-polymerase chain reaction. **Conclusions:** CD103+ T cells are preferentially accumulated in human livers, and those T cells show characteristics of extrathymic T cells.

Tada, M., O. Yokosuka, et al. (2005). "Hypermethylation of NAD(P)H: quinone oxidoreductase 1 (NQO1) gene in human hepatocellular carcinoma." Journal of Hepatology **42**(4): 511.

<http://www.sciencedirect.com/science/article/B6W7C-4DX25H6-2/2/d3cdfa20c05f3841b4415070e239965c>

Background/Aims: NAD(P)H: quinone oxidoreductase 1 (NQO1) and glutathione S-transferase P1 (GSTP1) belong to phase II xenobiotic-metabolizing enzymes. GSTP1 inactivation via CpG island

hypermethylation in hepatocellular carcinoma (HCC) was previously reported, but the involvement of NQO1 in HCC is not well known. In this study, we assessed the transcription and status of methylation of NQO1 gene in human hepatoma cells and primary human HCC tissues. Methods NQO1 transcription and DNA hypermethylation in hepatoma cells with or without 5-aza-deoxycytidine (5-Aza-CdR) treatment were investigated by reverse-transcription PCR (RT-PCR), sodium bisulfite sequencing and methylation-specific PCR (MSP). The methylation status of NQO1 and GSTP1, and NQO1 mRNA in 44 HCC cases was also analyzed by MSP and real-time PCR, respectively. Results NQO1 transcription was down-regulated and the CpG island DNA was hypermethylated in Hep3B and HuH6 cells. After treatment with 5-Aza-CdR, NQO1 transcription was restored and CpG island DNA was demethylated in these cells. MSP analysis revealed that NQO1 hypermethylation occurred in 50.0% of HCC. All of the tumors that exhibited lesser amounts of NQO1 mRNA than corresponding non-tumorous tissues showed NQO1 hypermethylation. Conclusions NQO1 transcription might be inappropriately suppressed by promoter hypermethylation in a subset of HCC, as well as GSTP1 gene.

Tanaka, A., T. P. Prindiville, et al. (1999). "Are infectious agents involved in primary biliary cirrhosis? A PCR approach." *Journal of Hepatology* **31**(4): 664.

<http://www.sciencedirect.com/science/article/B6W7C-437YTX1-58/2/4be075b047733ff704d1380c1f9a9cdf>

Background/Aims: A variety of data suggest that microbial infections and, in particular, atypical mycobacteria infections, may either initiate and/or be associated with the pathogenesis of primary biliary cirrhosis. Methods: To address this hypothesis, use was made of polymerase chain reaction techniques and primers specific for the 16s rRNA gene of Eubacteria, Archaeabacteria, Mycobacteria and Helicobacter to determine if such sequences were detectable in liver tissue specimens from 29 patients with primary biliary cirrhosis. Similar liver tissues from patients with primary sclerosing cholangitis, chronic hepatitis, alcoholic liver disease and otherwise normal donors were analyzed in parallel. Genomic DNA was extracted from each of these liver tissue specimens using sterile techniques to avoid possible laboratory contamination. The DNA was subjected to polymerase chain reaction amplification using bacterial genus specific primers and the amplified products cloned and sequenced. Sequence data were analyzed by searching for homology to existing genes. Results: Sequences from primary biliary cirrhosis and control livers corresponded to those found in a variety of bacteria, but no consensus sequence was found in primary biliary cirrhosis specimens. Neither Archaeabacteria nor Mycobacteria products were detected in liver specimens of patients with primary biliary cirrhosis, and Helicobacter pylori DNA was detected in only one primary biliary cirrhosis patient. Conclusions: Although bacterial infection, particularly with intracellular organisms, has been suggested to play a role in the initiation of primary biliary cirrhosis, there is no evidence from this study to suggest an ongoing chronic infectious process.

Tuveri, R., F. Jaffredo, et al. (2000). "Impact of TT virus infection in acute and chronic, viral- and non viral-related liver diseases." *Journal of Hepatology* **33**(1): 121.

<http://www.sciencedirect.com/science/article/B6W7C-436FWR9-DC/2/8d13f2dd3719242a1a238650ffbfa72f>

Background/Aims: The prevalence and pathogenicity of TT virus, recently identified in patients with non A-non G post-transfusional hepatitis, are questioned. Methods: We investigated the impact of this new viral infection in a large series of patients with non A-non G, cryptogenic, non-viral and viral-related, acute and chronic liver diseases (n=577) and blood donors (n=300). TTV DNA was detected in serum by heminested polymerase chain reaction. Phylogenetic analysis

was performed in 13 isolates. Results: TTV DNA was detected in 6/25 and 15/127 patients with cryptogenic non A-non G acute and chronic liver disease, respectively. TTV DNA positive subjects with post-transfusional acute hepatitis scored negative before transfusion. TTV prevalence was increased in patients with cryptogenic non A-non G acute and chronic liver disease compared to blood donors (6/300; ppConclusions: These results support the view that TTV is a widely spread infectious agent with a weak pathogenicity. It raises the possibility, however, that TTV might be implicated in a few cases of acute and chronic non A-non G hepatitis. TTV-DNA-analysed sequences are related to genotypes 1 and 2 described in Europe.

Uyama, N., Y. Shimahara, et al. (2003). "Carbenoxolone inhibits DNA synthesis and collagen gene expression in rat hepatic stellate cells in culture." Journal of Hepatology **39**(5): 749.

<http://www.sciencedirect.com/science/article/B6W7C-49CTBJP-5/2/aab5518c2bd177a427f2fe3c9f6f4e93>

Background/Aims: This study using primary-cultured rat hepatic stellate cells (HSCs) was aimed to reveal the effect of carbenoxolone and the other gap-junction blockers on the proliferation and activation of HSCs. Methods: HSC morphology was microscopically evaluated. DNA synthesis was determined by [³H]thymidine incorporation. Expression of HSC activation markers and cell cycle-related proteins was evaluated by Western blot. Collagen [alpha]1(I) mRNA expression was evaluated by quantitative reverse transcription polymerase chain reaction. Results: Carbenoxolone triggered the morphological change of activated HSCs without inducing apoptosis. Culture-induced DNA synthesis was suppressed to 22.6 and 8.51%, respectively, by 40 and 80 [mu]M carbenoxolone. The other gap-junction blockers failed to affect the morphology and the DNA synthesis of activated HSCs. Carbenoxolone decreased the expression of cyclins D1/2 and cyclin-dependent kinases 4/6. Platelet-derived growth factor (PDGF)-BB-elicited DNA synthesis was reduced to 45.6 and 3.27%, respectively, by 40 and 80 [mu]M carbenoxolone. Phosphorylation of c-Raf, MEK and mitogen-activated protein kinase, but not PDGF receptor [beta], under PDGF-BB stimulation was attenuated by carbenoxolone. Collagen [alpha]1(I) mRNA expression was significantly reduced. In addition, carbenoxolone suppressed the activation process of quiescent HSCs. Conclusions: Carbenoxolone reduced the DNA synthesis and the expression of collagen [alpha]1(I) mRNA in activated HSCs independently of its pharmacological action as gap-junction blocker.

Vidigal, P. G., J. J. Germer, et al. (2002). "Polymorphisms in the interleukin-10, tumor necrosis factor-[alpha], and transforming growth factor-[beta]1 genes in chronic hepatitis C patients treated with interferon and ribavirin." Journal of Hepatology **36**(2): 271.

<http://www.sciencedirect.com/science/article/B6W7C-44B6RS5-2/2/3bf748c5024e47ba1cffe7bc829ee049>

Background/Aims: In hepatitis C infection, the production of inappropriate cytokine levels appears to contribute to viral persistence and to affect the response to antiviral therapy. Additionally, polymorphisms in the cytokine genes may affect the production of the cytokines. In this study, we determined the frequency of the genotypes associated with polymorphisms of the interleukin-10 and tumor necrosis factor-[alpha] gene promoters, and transforming growth factor-[beta]1 gene leader sequence, and investigated their association with clinical features and the response to interferon-[alpha] and ribavirin therapy in chronic hepatitis C infection. Methods: Genomic DNA from 80 patients and 37 racially matched healthy controls was studied by polymerase chain reaction and direct automated sequencing. Results: The interleukin-10 -1082 G/G genotype was identified more frequently in patients than in controls (P=0.048). The transforming-growth factor-[beta]1 +29 (codon 10) C/C genotype was associated with resistance to the therapy (P=0.029).

After adjusting for potential confounding variables, patients exhibiting the C/C genotype were less likely to respond to treatment than patients with the T/T or T/C genotypes. Conclusions: These results suggest that inheritance of the interleukin-10 -1082 G/G and the transforming growth factor- β 1 +29 C/C genotypes, which appear to affect the cytokine production, may be associated with susceptibility to chronic hepatitis C infection and resistance to combined antiviral therapy.

Vona, G., R. Tuveri, et al. (2004). "Intrahepatic hepatitis C virus RNA quantification in microdissected hepatocytes." Journal of Hepatology **40**(4): 682.

<http://www.sciencedirect.com/science/article/B6W7C-4BDVY20-1/2/1e7a74500676dc4c2f83924dc53e3c80>

Background/Aims: Debate continues on whether serum and intrahepatic HCV viral loads are correlated and if HCV viral load correlates with the severity of liver disease. These difficulties may at least in part be linked to liver cell heterogeneity, when total liver extracts from HCV-infected individuals are tested for HCV RNA quantification. We have therefore investigated the feasibility of quantifying HCV replication using a laser-based microdissection technique. **Methods:** We compared the results with those obtained for serum HCV RNA quantification and immunochemistry in the case of HCV antigen detection in the liver. Twenty-one HCV-positive patients with chronic active hepatitis (n=10) or cirrhosis (n=11) were analyzed. **Results:** A positive correlation (P=0.0019) was observed between HCV RNA quantifications in sera and microdissected cells. Immunohistochemistry demonstrated that HCV antigen hepatocytes were randomly distributed within liver lobules. Their percentage varied in different patients (0-40%), but did not correlate with the HCV viral load. **Conclusions:** We have designed a sensitive methodology to evaluate the intrahepatic HCV viral load by combining a standardized RNA quantification method with microdissected hepatocytes from frozen liver needle biopsies. Our results directly demonstrate a positive correlation between serum and intrahepatic viral loads, which therefore provides a reliable reflection of intrahepatic HCV replication.

Watanabe, T., M. Niioka, et al. (2000). "Gene expression of interstitial collagenase in both progressive and recovery phase of rat liver fibrosis induced by carbon tetrachloride." Journal of Hepatology **33**(2): 224.

<http://www.sciencedirect.com/science/article/B6W7C-436FWWH-F3/2/0460c8b1435c3048239abd1de7e6d51c>

Background/Aims: Liver fibrosis is a dynamic state between matrix production and degradation. Since our report in 1974, many studies have examined collagenase and liver fibrosis, but not the identification of cells responsible for collagenase production in vivo. The aim of this study was to investigate the gene expression of interstitial collagenase in the progressive and recovery phases of experimental rat liver fibrosis by in situ hybridization. **Methods:** We examined the gene expression of interstitial collagenase (MMP-13) in the progressive and recovery phase of experimental rat liver fibrosis induced by chronic CCl₄ intoxication by reverse transcription-polymerase chain reaction (RT-PCR) and in situ hybridization. In order to identify the cells expressing MMP-13 mRNA by in situ hybridization, immunohistochemistry was performed using serial sections. **Results:** In normal rat liver, a faint band for MMP-13 mRNA was observed by RT-PCR, but not by in situ hybridization. The livers of rats treated with CCl₄ for 4 weeks showed fatty metamorphosis but no definite fibrosis. Positive signals for MMP-13 mRNA were observed in scattered mesenchymal cells, within lobules which seem to be stellate cells from immunohistochemical staining. Once the fibrosis became prominent, the faint band for MMP-13 mRNA was detected only by RT-PCR and very few signals, if any, by in situ hybridization. On the

other hand, in the recovery phase of liver fibrosis, gene expression of MMP-13 was markedly enhanced. Strong positive cells by in situ hybridization were observed mainly at the interface between the resolving fibrous septa and the parenchyma. Overlapping both images of in situ hybridization and immunohistochemical staining with the help of a computer revealed that some positive cells, but not all cells, were stellate cells stained with [alpha]-smooth muscle actin antibody. Conclusions: MMP-13 participates in the degradation of newly-formed matrix in the recovery from rat liver fibrosis more than in the remodeling of extracellular matrix for the formation of fibrosis. Hepatic stellate cells play a crucial role in MMP-13 production in the recovery from fibrosis, though not all stellate cells were positive for MMP-13 mRNA. Further investigation into gene expression of MMP-13 in recovery will lead to new strategies for the treatment of liver cirrhosis.

Yano, H., K. Fukuda, et al. (1996). "Expression of Fas and anti-Fas-mediated apoptosis in human hepatocellular carcinoma cell lines." Journal of Hepatology **25**(4): 454.

<http://www.sciencedirect.com/science/article/B6W7C-44FMNJ7-PS/2/12a754cbd7d611296f2d5c35965b036f>

Background/Aims: Fas transduces apoptotic signals upon cross-linking with the Fas ligand, which is experimentally replaced by anti-Fas antibodies. Because little is known about Fas expression and function in hepatocellular carcinoma, these issues are addressed in the current article. Methods: We examined Fas expressions at protein and mRNA levels, and susceptibility to anti-Fas-mediated apoptosis, on six hepatocellular carcinoma cell lines. Results: Two cell lines constitutively expressed high levels of Fas both on their cell surface and in their cytoplasm, whereas the other four cell lines expressed Fas mainly in their cytoplasm. Fas mRNA of normal size was detected in all cell lines in reverse transcriptase-polymerase chain reaction analyses. Although a Fas mRNA variant, suggesting soluble Fas molecule, was detected in the two cell lines expressing high levels of Fas, its amount was very small compared to that of normal-sized Fas transcript. Anti-Fas dose-dependently induced apoptosis exclusively in the two cell lines which constitutively express high levels of cell surface Fas. However, after preincubation with interferon-[gamma], one cell line with low surface Fas expression became anti-Fas sensitive equivalent to the two cell lines expressing surface Fas at high levels. Studies of two clonally related cell lines showed that dedifferentiated clones had lower Fas expression and resistance to anti-Fas, suggesting deterioration of Fas system after clonal cell dedifferentiation. Conclusions: These findings suggest sensitivity to anti-Fas is virtually relevant to cell surface Fas, but not to cytoplasmic Fas expression. However, its expression level does not correlate to sensitivity to anti-Fas.

Zein, N. N., A. S. Abdulkarim, et al. (2000). "Prevalence of diabetes mellitus in patients with end-stage liver cirrhosis due to hepatitis C, alcohol, or cholestatic disease." Journal of Hepatology **32**(2): 209.

<http://www.sciencedirect.com/science/article/B6W7C-436FVXF-6X/2/18366927d1bba18c941a936ff18e4162>

Background/Aims: The aims were to study: 1) the prevalence of diabetes mellitus in patients with end-stage liver cirrhosis due to hepatitis C, alcohol, or cholestatic liver disease, 2) viral and host immunogenetic factors that may predispose to diabetes, and 3) liver transplantation outcome in patients with or without diabetes. Methods: Fasting blood glucose values of patients who underwent liver transplantation because of hepatitis C-related cirrhosis (73 patients) were compared with those of patients with cirrhosis due to cholestatic (78 patients) or alcoholic liver disease (53 patients) and to a general population. Data on diabetes prevalence in a population

without liver cirrhosis was based on the prevalence of diabetes in Olmsted County, Minnesota, residents. HLA was determined using serologic assays. Hepatitis C virus genotypes were determined with polymerase chain reaction amplification and direct sequencing. Hepatitis G RNA was detected with polymerase chain reaction. Liver transplantation outcome in patients with or without diabetes was determined with rejection, retransplantation, or death at 1 year after transplantation as end points. Results: Of 64 patients with hepatitis C alone, 16 (25%) had diabetes before transplantation compared with 1 of 78 (1.3%) with cholestatic liver disease ($p=0.0001$) and 10 of 53 (19%) with alcoholic liver disease ($p=0.36$). Nine patients had hepatitis C plus cholestatic liver disease; one of these (11%) had diabetes. The prevalence of diabetes in patients with cholestatic liver cirrhosis was not different from that of the general population. The frequency of hepatitis G virus coinfection, HLA-DR3, or HLA-DR4 in hepatitis C and diabetes was not different from that of hepatitis C alone. The distribution of hepatitis C virus genotype was similar in those with and those without diabetes. Diabetes was not associated with increased risk of rejection, retransplantation, or death at 1 year after transplantation, and had no impact on overall survival after transplantation. Conclusions: 1) The risk of diabetes is not increased in patients with liver cirrhosis due to cholestatic liver disease but is in patients with liver cirrhosis due to hepatitis C or alcoholic liver disease; 2) cofactors (age, sex, body mass index, hepatitis G virus coinfection, hepatitis C virus genotype, or HLA-DR3/DR4) did not explain the increased risk of diabetes in patients with hepatitis C; 3) diabetes before liver transplantation did not change the outcome at 1 year after transplantation or survival.

Chiew, Y. F. and L. M. C. Hall (1998). "Comparison of three methods for the molecular typing of Singapore isolates of enterococci with high-level aminoglycoside resistances." Journal of Hospital Infection **38**(3): 223.

<http://www.sciencedirect.com/science/article/B6WJP-4CDJ0YX-8/2/be18b13d8fc4a465721b243c12f7b9b4>

Enterococci are frequently isolated as nosocomial pathogens and have often acquired intrinsic drug resistances. Molecular typing techniques have been developed to assist in epidemiological and infection control measures. This study investigates enterococci with high-level aminoglycoside resistance (HLAR) from the National University Hospital (NUH) of Singapore, and evaluates and compares three methods for typing: restriction enzyme analysis by conventional gel electrophoresis [restriction fragment length polymorphism (RFLP)], pulsed-field gel electrophoresis (PFGE), and polymerase chain reaction (PCR) using random amplified polymorphic DNA (RAPD). Fifty-two isolates of *Enterococcus faecalis* and 13 isolates of *Enterococcus faecium* were used for the study. The numbers of patterns obtained for *E. faecalis* and *E. faecium* were 26 and 4, respectively by the RFLP method, and very similar discrimination was obtained by PFGE. RAPD PCR results were not reliably reproducible. A single pattern type by RFLP accounted for 16 of the *E. faecalis* isolates, suggesting hospital spread.

Loudon, K. W., A. P. Coke, et al. (1996). "Kitchens as a source of *Aspergillus niger* infection." Journal of Hospital Infection **32**(3): 191.

<http://www.sciencedirect.com/science/article/B6WJP-4C7633Y->

1H/2/9fca7908a67e0478a30d86b22390fc03

In this study we investigated the epidemiology of a cluster of cutaneous infections owing to *Aspergillus niger*, which occurred in neutropenic patients in a bone marrow transplant unit. Heavy environmental contamination with the mould was found in the ward kitchen adjacent to the unit. The clinical and environmental isolates were typed by random amplification of polymorphic DNA (RAPD), which showed one of the patients was infected with the same strain as that isolated repeatedly from the kitchen area. In another case, contaminated stockinette material was implicated as the source of infection. Thorough cleaning of the ward kitchen resulted in no further cases on the unit. This highlights the fact that aspergilli may spread to patients by air, food or other vehicles, and underlines the importance of searching for a source and ensuring high levels of hospital hygiene are maintained.

Skibsted, U., D. L. Baggesen, et al. (1998). "Random amplification of polymorphic DNA (RAPD), pulsed-field gel electrophoresis (PFGE) and phage-typing in the analysis of a hospital outbreak of *Salmonella* Enteritidis." *Journal of Hospital Infection* **38**(3): 207.

<http://www.sciencedirect.com/science/article/B6WJP-4CDJ0YX-6/2/20297cd3c4e6394eb02fa38c441c3d3e>

Isolates of *Salmonella* Enteritidis from 81 patients from Herlev Hospital or from Copenhagen County were analysed by random amplification of polymorphic DNA (RAPD), pulsed-field gel electrophoresis (PFGE) and phage-typing. Fourteen polymorphic markers from five decamer primers unambiguously placed all isolates into six RAPD groups: 65 isolates of phage-type 6 (PFGE type I) were resolved into three RAPD groups constituting 86, 12, and 2%, respectively. A fourth RAPD group of 10 isolates was coincident with phage type 8 (PFGE type II) and two isolates, one phage-type 1, the other phage-type 4 (both PFGE type I) formed the fifth group. The sixth group of four isolates was not phage typeable and was PFGE type III. Forty outbreak-related isolates of phage-type 6 were resolved into three strains. No diversity of phage-type 6 was found among isolates unrelated to the outbreak. It is concluded that RAPD is useful as a tool in investigations of microbial outbreaks in its own right, or to supplement phage-typing and PFGE of *Salmonella* Enteritidis.

Xu, J., C. L. Smyth, et al. (2004). "Employment of 16 S rDNA gene sequencing techniques to identify culturable environmental eubacteria in a tertiary referral hospital." *Journal of Hospital Infection* **57**(1): 52.

<http://www.sciencedirect.com/science/article/B6WJP-4C59SHV-2/2/369500e641c6fb788f1db3e26453da6e>

Universal or 'broad-range' eubacterial polymerase chain reaction (PCR) was performed on 53 isolates from environmental water-associated sites in a haematology unit (N=22), and the outer surfaces of cleaning lotion containers sited throughout a tertiary referral hospital (N=31). 16 S rDNA PCR was performed using two sets of universal primers, including the novel reverse primer, XB4, to generate a composite amplicon of 1068 bp, which was sequenced to obtain each isolate's identity. Sequence analysis was able to identify 51 isolates. Most (75% from the haematology unit and 81% from cleaner containers) were Gram-positive. Nine different genera were identified from the haematology unit and 13 from the cleaning lotion containers. This study provides the first reports of *Terrabacter* spp. and *Brachybacterium paraconglomeratum* isolated from a hospital environment. As unusual and difficult-to-identify environmental organisms are unlikely to be clinically significant, and molecular identification is costly and labour-intensive, we

recommend that molecular methods are only used as an adjunct to first-line phenotypic identification schemes where a definitive identification is required. Where molecular identification methods are justified, partial 16 S rDNA PCR and sequencing employing the novel universal primer XB4, is a valuable and reliable technique.

Journal of Immunological Methods (52)

Bardwell, P. D., A. Martin, et al. (2002). "Mutation detection of immunoglobulin V-regions by DHPLC." Journal of Immunological Methods **266**(1-2): 165.

<http://www.sciencedirect.com/science/article/B6T2Y-45XTD29-3/2/324036213b140f52aad861eec3b44d85>

One of the key features in the affinity maturation of antibodies is somatic hypermutation of the variable regions of immunoglobulin genes. The mutations that occur in immunoglobulin genes are detected by direct sequencing of cloned polymerase chain reaction (PCR) products. The frequencies of mutations in vivo are generally high enough to provide sufficient numbers of point mutations in order to generate large databases that can be analyzed in various ways. Recently, the mechanisms of variable (V)-region hypermutation have been studied in tissue culture systems and transgenic mice where mutation occurs at frequencies that are ~10-fold lower than the estimated in vivo rate. Identifying mutations by brute force sequencing of PCR products in comparative studies is limiting when trying to determine if there are statistically significant differences. Here we describe a high throughput technique that can facilitate the identification of immunoglobulin V-regions that contain one or more mutations before sequencing. This technique, known as denaturing high-performance liquid chromatography (DHPLC), utilizes a standard HPLC apparatus with a column that binds double-stranded DNA (dsDNA). In this study, we have successfully detected ~90% of previously sequenced mutated V-regions by DHPLC. Our results show that we were able to detect mutations throughout a 321-base pair (bp) region of the Ricin 45 immunoglobulin (Ig) V-region. Also, with the use of this assay, we have been able to detect mutations in multiple clones of different immunoglobulin genes.

Becknell, B., R. Trotta, et al. (2005). "Efficient infection of human natural killer cells with an EBV/retroviral hybrid vector." Journal of Immunological Methods **296**(1-2): 115.

<http://www.sciencedirect.com/science/article/B6T2Y-4F05PSP-3/2/d67a6027b3c136fde2cc6881daeb97f4>

Molecular characterization of human natural killer (NK) cells will require targeted gene delivery to inhibit and activate specific signaling pathways, yet to our knowledge, an effective means to deliver such products for long-term gene expression without disrupting normal cellular processes has not been described. In this study, we have developed a retroviral strategy to effectively express gene products in the NK cell, whereby its effector functions of cytotoxicity and cytokine production remain intact. Using an EBV/retroviral hybrid vector, we demonstrate infection of human peripheral blood NK cells with simultaneous expression of a marker for infection-the enhanced green fluorescent protein (EGFP)-along with various genes of interest. This technique results in successful infection of the CD56dim NK population that predominates among human peripheral blood NK and is the effector of antibody-dependent cellular cytotoxicity and natural

killing. In addition, we demonstrate infection of the CD56bright NK subset as well as the NK-92 cell line. In summary, we have devised an efficient and reproducible methodology for the targeted delivery of gene products to human NK cells that should now provide opportunities to dissect the molecular processes critical to normal NK cell physiology.

Bertolotto, A., F. Gilli, et al. (2001). "Evaluation of bioavailability of three types of IFN[beta] in multiple sclerosis patients by a new quantitative-competitive-PCR method for MxA quantification." Journal of Immunological Methods **256**(1-2): 141.

<http://www.sciencedirect.com/science/article/B6T2Y-43RVDJ7-D/2/41557e57795fa8085696464abc5b87fb>

Intracellular expression of human myxovirus protein A (MxA) is exclusively induced by type I IFNs (IFN[alpha],[beta],[omega]) or by some viruses and it is strongly increased under IFN treatment. We set up an internally controlled quantitative-competitive polymerase chain reaction (qc-PCR) that quantifies MxA mRNA expressed in human peripheral blood mononuclear cells (PBMC). Our qc-PCR is accurate because the mean ratio of copy number estimated by qc-PCR to that quantified spectrophotometrically is 1.08 ± 0.03 , moreover it is repeatable with high sensitivity (1 fg MxA/pg GAPDH). MxA mRNA was tested in 47 Relapsing-Remitting Multiple Sclerosis (RR-MS) untreated patients and in 48 patients treated with one of the 3 IFN[beta] licensed for MS (24 with Rebif, 14 with Avonex and 10 with Betaferon). All the 48 treated patients were negative to IFN[beta] neutralising antibodies (NABs) as tested in our laboratory using a cytopathic assay (CPE). MxA mRNA levels were detectable in all untreated patients (mean 24 ± 18 fg MxA/pg GAPDH) and significantly higher levels were found in all the treated patients 12 h after IFN[beta] administration (mean 499 ± 325 fg MxA/pg GAPDH); furthermore, the three types of IFN[beta] showed comparable bioavailability. Our data indicate that the bioavailability of the three available types of IFN[beta] can be evaluated by MxA qc-PCR.

Bettinotti, M. P., L. Hadzikadic, et al. (2003). "New HLA-A, -B, and -C locus-specific primers for PCR amplification from cDNA: application in clinical immunology." Journal of Immunological Methods **279**(1-2): 143.

<http://www.sciencedirect.com/science/article/B6T2Y-48V7JYK-1/2/be8fc33b7e1ce4739fababb4d45dc8c1>

The individual cellular immune response to intracellular antigens is modeled by the highly polymorphic major histocompatibility complex (HLA) class I molecules. The epitopes presented and the T cell repertoire that recognizes them depend on the HLA constitution of the individual. Therefore, to monitor and to modify an individual's HLA class I-driven cellular immune response, it is necessary to know the HLA class I alleles of the person and the possible epitopes of the target antigen presented by those alleles. In particular, this is necessary in order to design peptide-based vaccines and immune therapies for the treatment of diseases caused by viruses, intracellular parasites or cancer, and to monitor the immune response during those treatments. We describe a new set of HLA-A, -B, and -C locus-specific primers for the polymerase chain reaction (PCR) amplification of the whole coding sequence of these genes from complementary DNA (cDNA). We describe their use for typing and for the production of a library of recombinant HLA class I genes. We discuss two downstream applications of this gene collection: production of soluble HLA molecules and discovery of new epitopes.

Brostjan, C., T. Bellon, et al. (2002). "Differential expression of inhibitory and activating CD94/NKG2 receptors on NK cell clones." Journal of Immunological Methods **264**(1-2): 109.

<http://www.sciencedirect.com/science/article/B6T2Y-45NGR13-1/2/ab807ca30531cbeeeeb69d7d09e334ec>

Natural killer cells are known to express a variety of surface receptors involved in HLA class I monitoring. It is thus of interest to investigate the clonal distribution and relative expression levels of activating versus inhibitory NK receptors. We have developed a quantitative real-time reverse transcription-polymerase chain reaction (RT-PCR) assay designed to determine specific and absolute mRNA levels for NKG2-A/B, -C, -E, -F, -H and NKG2-D. When analyzing NK cell clones derived from a single donor we found differential expression of inhibitory (NKG2-A/B) versus triggering (NKG2-C and potentially -E, -F, -H) NK receptor chains. The generation of the splice variants NKG2-E and -H seemed to occur at a constant ratio. We further compared NKG2 transcript levels to surface receptor expression as monitored by flow cytometric analysis and to NK cell cytotoxicity as detected by reverse ADCC: a clear correlation was observed. Thus, the data obtained reveal a substantial variability in the NKG2 repertoire among NK cell subpopulations, which is likely to affect the sensitivity and reactivity towards the ligand HLA-E.

Calaman, S. D., G. R. Carson, et al. (1993). "Characterization of monoclonal antibodies specific for the V[beta]3 family of the human T cell receptor generated using soluble TCR [beta]-chain." Journal of Immunological Methods **164**(2): 233.

<http://www.sciencedirect.com/science/article/B6T2Y-476MXMB-133/2/2bca130d9534808aca16ae9c9c239ef5>

A soluble, recombinant form of the human T cell receptor (TCR) [beta]-chain containing the V[beta]3.1 sequence has been constructed, expressed in Chinese hamster ovary cells, amplified by dihydrofolate reductase selection, and purified in quantities appropriate for the generation of monoclonal antibodies (mAb). The V[beta]3 sequence was chosen because of its reported elevated usage in the synovial T cells of rheumatoid arthritis patients but the approach described should be applicable to other known human V[beta] gene sequences. By this method, two mAb were prepared which reacted with up to 10% of normal, live peripheral blood T cells but with reactivity varying greatly among individual donors. Both mAb specifically bound to a murine T cell line transfected with a human TCR V[beta]3.1 and immunoprecipitated a protein of the expected molecular weight for the TCR [beta]-chain. Both antibodies were mitogenic for T cells and analysis of peripheral blood lymphocyte cultures stimulated with the mAb suggested that both were specific for the V[beta]3.1 subfamily and not D[beta] or J[beta]. Clones expressing V[beta]3, which were derived from mAb-stimulated peripheral blood lymphocytes of a single individual, preferentially (8/13), but not exclusively, utilized the J[beta]2.7 gene segment. The V[beta]3.1 usage showed no preference for the CD8+ or CD4+ subpopulations of normal peripheral blood T cells.

Case, M. C., A. D. Burt, et al. (1999). "Enhanced ultrasensitive detection of structurally diverse antigens using a single immuno-PCR assay protocol." Journal of Immunological Methods **223**(1): 93.

<http://www.sciencedirect.com/science/article/B6T2Y-3VM79Y0-8/2/4adaf90c67f04dd070f2953d34c9b5a6>

Our studies of DNA damage and repair in autoimmune disease, lymphomagenesis, and carcinogenesis, require identification of an immunoassay approach that is capable of

ultrasensitive detection in a routine human tissue biopsy of several physicochemically diverse antigens, some of which will be present at very low level. Immuno-polymerase chain reaction (immuno-PCR) is a recently described method for ultrasensitive antigen detection that combines the amplification power of PCR with a method similar to a standard antibody capture, enzyme-linked immunosorbent assay (ELISA). As a test of the universality of immuno-PCR, and as an assessment of the suitability of this method for our studies, we used a single immuno-PCR protocol to assay purified forms of the following physicochemically diverse antigens: oligomeric pyruvate dehydrogenase complex (PDC; Mr 8.5×10^6), the promutagenic DNA base adduct O6-methylguanosine (Mr 298) and its monomeric repair enzyme, O6-methylguanine-DNA methyltransferase (MGMT; Mr 22,000), and a peptide from the N-terminus of MGMT (Mr 2310). We found that all antigens could be ultrasensitively assayed using the single immuno-PCR protocol. Assay limits observed using antigen-specific (primary) antibodies at 1 $\mu\text{g/ml}$, were in the approximate range of 10^2 - 10^9 molecules, with O6-methylguanosine being detected most sensitively. Sensitivity of the antigen assay appeared to positively correlate with primary antibody titres determined by ELISA. Furthermore, we observed a substantial increase in detection sensitivity for all antigens by the use of primary antibodies at the higher level of 10 $\mu\text{g/ml}$. The latter approach permitted antigen assay within the approximate range of 10^2 - 10^7 molecules. The combination of higher titre primary antibodies and their use at higher input level, produced an increase of immuno-PCR assay sensitivity of up to four orders of magnitude greater than those previously reported through the use of this assay to measure other antigens. This represents up to a nine order of magnitude increase in immunoassay sensitivity compared to ELISA. Our findings provide compelling evidence that immuno-PCR is indeed a universal ultrasensitive antigen detection method. Using the indicated assay enhancements, immuno-PCR performed as detailed here can offer greatly increased sensitivity for antigen measurement compared to other methods. Thus, our findings suggest that parallel quantitation of several different antigens in very small samples of human tissue will be readily attainable using immuno-PCR.

Cohen, P., D. Laune, et al. (2001). "Interaction of the octapeptide angiotensin II with a high-affinity single-chain Fv and with peptides derived from the antibody paratope." Journal of Immunological Methods **254**(1-2): 147.

<http://www.sciencedirect.com/science/article/B6T2Y-4378WTW-D/2/df443a60effa7949fa96c45962399506>

The amino-acid sequence of the very high-affinity anti-angiotensin II monoclonal antibody 4D8 was predicted from the nucleotide sequence of the heavy and light chain variable genes. The single-chain variable fragment (scFv) was constructed and expressed in *Escherichia coli* as a soluble protein and at the surface of the filamentous M13 phage and was compared with the full-length antibody (Ab). The scFv showed the same specificity profile and affinity constant as the intact antibody (5.0×10^{10} and $8.0 \times 10^{10} \text{ M}^{-1}$, respectively, by Scatchard analysis). Several peptides from the set of overlapping dodecapeptides covering the variable domains of 4D8 mAb were found to specifically bind biotinylated angiotensin II: peptides from the L1, L2, L3 and H1 regions had the strongest capacity to bind the antigen.

Damoiseaux, J. G. M. C., R. Theunissen, et al. (1998). "Comparison of detection techniques for cytokine reverse transcriptase polymerase chain reaction; digoxigenin-labeled polymerase chain reaction permits sensitive detection of cytokine mRNA in rat heart allografts." Journal of Immunological Methods **217**(1-2): 185.

<http://www.sciencedirect.com/science/article/B6T2Y-3TXK8XS-N/2/400ecc2f67f08dbd77793629e7a3a13d>

The polymerase chain reaction (PCR) is a sensitive method for the analysis of cytokine mRNA expression. The amount of specific mRNA in tissues involved in an inflammatory immune response can be low and therefore requires highly sensitive detection of the PCR products. In our study we have compared different detection techniques in order to replace the commonly used detection by means of radiolabeled probes. Besides the detection of DNA in agarose gels by ethidium bromide (EB), we used detection by digoxigenin (DIG)-labeled probes, as well as the direct incorporation of DIG-labeled nucleotides in the PCR, in comparison to detection by means of labeled probes. In vitro activated rat lymph node cells, lymph node tissue, and acutely or chronically rejected rat heart allografts were examined for expression of mRNA of the cytokines IL-2 and IFN[gamma]. The directly DIG-labeled PCR appeared to be the best alternative for detection of PCR products by means of radiolabeled probes. While IL-2 mRNA was not detected by means of EB and IFN[gamma] mRNA was only detected at the highest PCR cycle numbers in acutely and chronically rejected rat heart allografts, both cytokine mRNA's were readily detected by directly DIG-labeled PCR.

Den, W., S. R. Sompuram, et al. (1999). "A bidirectional phage display vector for the selection and mass transfer of polyclonal antibody libraries." Journal of Immunological Methods **222**(1-2): 45.

<http://www.sciencedirect.com/science/article/B6T2Y-3VCK4R5-4/2/a8a87f51cf7a47bc1195bd026f3b06b>

An approach to the creation of antigen-specific polyclonal libraries of intact antibodies is presented. A polyclonal library of Fab antibody fragments would be expressed using a phage display vector, and selected for reactivity with an antigen or group of antigens. For conversion into a sublibrary of intact polyclonal antibodies, the selected heavy (H) and light (L) chain variable (V) region gene combinations would be transferred in mass, as linked pairs, to a eukaryotic expression vector which provides immunoglobulin (Ig) constant (C) region genes. To enable this selection and transfer, a bidirectional phage display vector was generated, in which the V region gene pairs are linked head to head in opposite transcriptional orientations. The functionality of this vector was demonstrated by the selection, transfer and expression of linked V region gene pairs derived from an A/J mouse that had been immunized with p-azophenylarsonate (Ars)-coupled keyhole limpet hemocyanin (KLH). As expected, the expressed IgG2b anti-Ars antibodies with selected V region gene pairs were shown to have V region sequences and Ars-binding characteristics similar to those of anti-Ars hybridoma antibodies. The technology presented here has potential for many diagnostic and therapeutic applications. These include the generation of polyclonal antibody libraries against multiple epitopes on infectious agents or cancer cells, and of polyclonal libraries encoding chimeric molecules composed of antibody V regions and T cell receptor C regions.

Dufour, V., C. Arnault, et al. (1999). "Quantification of porcine cytokine gene expression using RT-PCR, a homologous internal control and chemiluminescence for microplate detection." Journal of Immunological Methods **229**(1-2): 49.

<http://www.sciencedirect.com/science/article/B6T2Y-3Y8N2FX-4/2/34120909a2ae4c792389927dea461ae5>

The polymerase chain reaction (PCR) has proved to be a sensitive and versatile method for the analysis of human and murine cytokine mRNA expression. This paper describes for the first time a reverse transcription-polymerase chain reaction (RT-PCR) at end-point for the quantification of five porcine cytokines: interferon (IFN)-[gamma], interleukin (IL)-2, IL-4, IL-10 and IL-18. The main features of the methodology are: (1) a unique RT for all quantifications, (2) the addition of homologous DNA internal controls (IC) of equal length to the corresponding cytokine and

consequently co-amplification of the target cytokine and the IC with equivalent efficacy, (3) PCR and detection of amplicons for all cytokines simultaneously, (4) cytokine quantification in relation to a housekeeping gene control (glyceraldehyde-3-phosphate dehydrogenase, GAPDH), (5) detection of the amplicons by enzyme linked immunosorbent assay (ELISA) using a chemiluminescent substrate with high sensitivity and wide dynamic range, (6) automation of the detection system for analysis of a large number of samples. This highly sensitive quantitative RT-PCR assay (able to detect 100-200 cytokines mRNA copies/75 x 10³ cells) was validated on peripheral blood mononuclear cells (PBMC) from pigs infected or not with pseudorabies virus (PRV), re-stimulated in vitro by a mitogen or antigens.

Ekerfelt, C., J. Ernerudh, et al. (2002). "Detection of spontaneous and antigen-induced human interleukin-4 responses in vitro: comparison of ELISPOT, a novel ELISA and real-time RT-PCR." Journal of Immunological Methods **260**(1-2): 55.

<http://www.sciencedirect.com/science/article/B6T2Y-447DF3N-4/2/23131ff534ab32980eff593fe3ff65d1>

Interleukin-4 (IL-4) is an important T-helper cell type 2 (Th2) cytokine in man, driving Th2 polarisation and exerting the most antagonistic effects to the Th1 cytokine interferon-[gamma] (IFN-[gamma]). Nevertheless, few data on spontaneous and antigen-specific secretion of IL-4 in man are available, mainly due to difficulties in the detection of IL-4. In this study, we compared three assays that can detect antigen-induced IL-4 responses; ELISPOT, ELISA after blocking the IL-4 receptor during cell culture, and real-time reverse transcription polymerase chain reaction (RT-PCR). Spontaneous, antigen- and allergen-induced responses were analysed in peripheral blood mononuclear cells from three groups with different secretion patterns for IL-4: atopic individuals, nonatopic individuals and pregnant women. ELISPOT displayed the highest sensitivity and was the only assay that could detect spontaneous secretion of IL-4 in all analysed samples. The IL-4 receptor blocking ELISA was considered best for the detection of in vitro antigen- and allergen-induced responses, since the results obtained from the ELISPOT and real-time RT-PCR displayed lower specificity, possibly because of seemingly aberrant IL-4 responses in the group of pregnant women. The real-time RT-PCR for detection of IL-4 mRNA proved to be sensitive, but expression of IL-4 mRNA was not correlated with the secretion of IL-4.

Feuchtenberger, M., H.-P. Tony, et al. (2003). "Semiquantitative and qualitative assessment of B-lymphocyte VH repertoire by a fluorescent multiplex PCR." Journal of Immunological Methods **276**(1-2): 121.

<http://www.sciencedirect.com/science/article/B6T2Y-48622T6-2/2/c6e9be04f7cbb856bc1140f45700db95>

We established a new tool to perform semiquantitative and qualitative screening for VH gene usage frequency during IgH rearrangements in human B-lymphocytes. In two separate multiplex PCRs, the rearranged VDJ regions were amplified with VH family-specific primers labeled with different fluorescent dyes (FAM, HEX, NED, or ROX). The relative amount of each of the particular VH family products and their ratios were determined by fragment analysis on a ABI PRISM 377 sequencer. We verified that the fluorescent multiplex PCR (FMPCR) shows high specificity and sensitivity, acceptable reproducibility and reliability. Data obtained were well in agreement with results revealed by sequencing following single-cell PCR. Ten healthy volunteers showed a comparable semiquantitative VH family distribution. The FMPCR also correctly detected a monoclonal peak in a CLL patient. Thus, labeling primers with various fluorescent dyes allows for an assessment of VH family usage and an immediate determination of the involved VH gene family if any clonal peaks are present. This method provides a quick, easy, and

reliable tool for VH repertoire screening of larger populations of patients suffering from diseases with changes in the VH repertoire allowing for selection of cases worth a more detailed and cumbersome sequence analysis later on.

Flores, M. G., S. Zhang, et al. (2004). "In vitro evaluation of the effects of candidate immunosuppressive drugs: flow cytometry and quantitative real-time PCR as two independent and correlated read-outs." *Journal of Immunological Methods* **289**(1-2): 123.

<http://www.sciencedirect.com/science/article/B6T2Y-4CG7PM4-2/2/52ce1d0bfeccc136aa8ecd89ef1c6be7>

Background: Immune monitoring may use flow cytometry or molecular biology techniques. Flow cytometry assays cells that are phenotypically characterized, whereas TaqMan(R) RT-PCR starts with RNA extraction from unfractionated heterogeneous cell populations. We therefore wondered how the effects of immunosuppressive drugs on cytokine production in stimulated whole blood, as determined by flow cytometry, would correlate with those obtained with quantitative real-time PCR (TaqMan(R) RT-PCR). Methods: Blood drawn from naive cynomolgus monkeys was exposed to incremental amounts of cyclosporine (CsA; 300, 600, 900 and 1200 ng/ml) or tacrolimus (TRL; 8, 20, 40 and 80 ng/ml) before lectin stimulation in vitro. Blood was then either stained for CD3, IFN-[gamma], IL-2, IL-4, and TNF-[alpha] and analyzed on a flow cytometer with various gating strategies, or submitted to RNA extraction for analysis of the above mentioned cytokines mRNA transcripts using TaqMan(R) RT-PCR. Results: Both methods revealed a parallel dose-dependent inhibition of cytokine production in stimulated blood. The 50% inhibitory concentrations (IC50's) ranged from 511-771 ng/ml (CsA) and 15-29 ng/ml (TRL) with flow cytometry, and from 275-529 ng/ml (CsA) and 11-48 ng/ml (TRL) with TaqMan(R) RT-PCR for T-helper 1 cytokines. Both assays correlated well with a Pearson product moment correlation of 0.76. Extending gating from a CD3+ gate to a lymphocyte gate improved correlation ($r=0.85$) for all cytokines investigated (except IL-2; unchanged) whereas further extending gating resulted, to the contrary, in lower correlations. Independent of gating strategy a high correlation ($r=0.97$) was observed when drug IC50's were considered. Conclusions: Flow cytometry and TaqMan(R) RT-PCR may be used interchangeably to monitor the effects of candidate immunosuppressive drugs on cytokine mRNA production in lectin-stimulated whole blood.

Frohn, C., P. Schlenke, et al. (1998). "DNA typing for natural killer cell inhibiting HLA-Cw groups NK1 and NK2 by PCR-SSP." *Journal of Immunological Methods* **218**(1-2): 155.

<http://www.sciencedirect.com/science/article/B6T2Y-3V78C2J-H/2/b69acd59079f74c5ab0873ec0928c732>

Over the last few years, natural killer (NK) cells have been shown to express MHC molecule recognizing receptors which are thought to function primarily as negative signaling receptors. HLA-Cw seems to play a key role as the corresponding ligand. Two distinct HLA-Cw groups which differ in amino acid residues 77 and 80 inhibit separate subsets of NK cells. In order to classify target cells with respect to their expression of HLA-Cw groups we established a group specific PCR-SSP which directly amplifies the relevant epitope coding sequences. The PCR protocol was validated by retyping cell lines obtained from the International Histocompatibility Workshop and by comparing those results with those acquired from allele-specific genotyping and serotyping on 80 donor-recipient pairs from our kidney transplantation unit. In the context of inhibitory HLA-Cw receptors, our protocol which definitively discriminates the two alternative epitopes is the more direct and thus more reliable approach, and is less labor intensive compared to an allele specific PCR or serotyping. In addition serotyping does not detect at all certain alleles. Basic NK cell research and clinical transplantation immunology may benefit from this newly

established PCR SSP technique.

Furuya, D., A. Yagihashi, et al. (2000). "An immuno-polymerase chain reaction assay for human interleukin-18." Journal of Immunological Methods **238**(1-2): 173.

<http://www.sciencedirect.com/science/article/B6T2Y-4007PM6-K/2/9f2fd1588a267afae8667856670ad8e5>

Conventional enzyme-linked immunosorbent assays (ELISA) are sufficient to measure normal and elevated serum interleukin (IL)-18 concentrations, but have limited sensitivity when measuring low concentrations of IL-18 such as in patients with the acquired immunodeficiency syndrome. We have developed a highly sensitive method for detecting human (h) IL-18 using an immuno-polymerase chain reaction (PCR). A mouse monoclonal anti-hIL-18 antibody and rabbit polyclonal anti-hIL-18 antibody was used for an indirect sandwich ELISA with a detection limit of 40 ng/l and a very low background. For immuno-PCR, biotinylated DNA was produced from the plasmid Bluescript by PCR amplification with biotinylated M13-20 primer and nonbiotinylated M13 reverse primer. Immuno-PCR for hIL-18 was performed for 40 cycles using 1 ng/l of biotinylated DNA. This immuno-PCR has a detection limit of 2.5 pg/l, 1.6×10^4 times lower than that of the ELISA. In addition, our system avoids sampling error caused by heat transfer from the ELISA plate to the PCR tube because all procedures from immobilization of the antibody to PCR amplification can be performed in the same tube. This immuno-PCR for hIL-18 is the most sensitive method for detecting hIL-18 reported to date.

Gallard, A., G. Foucras, et al. (2002). "Tracking T cell clonotypes in complex T lymphocyte populations by real-time quantitative PCR using fluorogenic complementarity-determining region-3-specific probes." Journal of Immunological Methods **270**(2): 269.

<http://www.sciencedirect.com/science/article/B6T2Y-46RCV6P-1/2/602f8f84b75d98b4fd25a3c18c3156a6>

The T cell receptor (TCR) [alpha] and [beta] chains are encoded by a series of stochastic rearrangements between variable (V), diversity (D) for TCR [beta] chain only, and joining (J) gene segments, creating hypervariable complementarity-determining region 3 (CDR3) regions that contact the peptide/MHC complex and confer specificity. In the present paper, we applied the recently developed real-time quantitative RT-PCR technique to the detection of rearranged TCR [beta] chain mRNA transcripts. We designed BV- and BJ-specific primers together with TaqMan(TM) probes specific for the CDR3 regions of the clones of interest. As an external reference, we used plasmids containing the entire TCR [beta] chains, making it possible to normalize the number of specific rearranged BV-J mRNA copies among the total number of TCR [beta] chains. Here, we present data validating this fluorogenic PCR-based method for the quantification of several TCR clonotypes characteristic of the CD4 T cell response to hen egg white lysozyme (HEL) in mice of the H-2d haplotype. This accurate and sensitive procedure permits the precise determination of T cell clone frequencies ranging from 10^{-2} to less than 10^{-5} in normal biological samples; it may provide an alternative approach when frequencies are too low to be assessed by flow cytometry.

Garcia-Pacheco, J. M., P. Mantilla, et al. (1995). "Routine HLA DRB/DQB oligonucleotide typing by a non-radioactive dot-blot micromethod." Journal of Immunological Methods **180**(1): 35.

<http://www.sciencedirect.com/science/article/B6T2Y-3Y6PRBM-34/2/ed5619582b64313be7ba345a3fc50a4e>

In the last few years the clinical need for HLA genotyping has become evident. However, the routine use of PCR-based DNA typing techniques has been hampered by economical and/or technical considerations. The classical PCR-SSO (product-dot) method has been widely tested and proven to be useful for large-scale HLA DNA typing. However, it is not a suitable method for routine typing of single samples because it takes several days. Using primers and probes for sequences identical to those compiled by the Eleventh International Histocompatibility Workshop, we designed a non-radioactive dot-blot technique in which each hybridization reaction is performed in a microtiter plate well containing PCR-amplified DNA that has been previously dotted on a small nylon membrane, so that a large number of oligonucleotide probes tailed with biotin-14-dATP can be simultaneously tested against the same sample. We studied 23 B-lymphoblastoid cell lines of known HLA genotype to test the method and, so far, it has been validated on more than 100 patients and healthy relatives typed prospectively. This simple, rapid, inexpensive PCR-SSO dot-blot micromethod makes DRB/DQB DNA typing of single samples possible in a short period of time, and is therefore an attractive alternative to serological typing in routine medical practice.

Govorko, D., G. Cohen, et al. (2001). "Single-chain antibody against the common epitope of mutant p53: isolation and intracytosolic expression in mammalian cells." Journal of Immunological Methods **258**(1-2): 169.

<http://www.sciencedirect.com/science/article/B6T2Y-448BKNV-K/2/e2d03b98bea939838205f13bb42a260d>

The peptide epitope FRHSVV is cryptic in wild-type p53 and is exposed in many types of mutant p53 molecules isolated from various tumors. Mutant p53 marked by this epitope abrogates a tumor-suppressor function of wild-type p53 and possibly contributes to the transforming potential of other oncogenic processes. We report here the construction of a single-chain scFv antibody gene library derived from the mRNA of a mouse immunized with the epitope peptide FRHSVV which mimics the common epitope in p53 mutant protein molecules. The scFv was presented by phage display. The selected antibody gene, named ME1, was found to bind to the mutant p53 protein but not to the wild-type p53 protein. Preliminary studies show that the ME1 gene is expressed in the cytosol of mammalian cells. These findings suggest that the ME1 single-chain antibody may be useful as a tool for clarifying the role of mutant p53 in tumor transformation, especially in cells heterozygous in p53, and possibly for gene therapy of tumors.

Grant, D. D., R. Goldstein, et al. (1999). "Elimination of non-viable 6-thioguanine-sensitive T cells from viable T cells prior to PCR analysis." Journal of Immunological Methods **225**(1-2): 61.

<http://www.sciencedirect.com/science/article/B6T2Y-3WJFCGC-6/2/a96e004dcd5a5436c78e1b0929ca35c9>

The study of T cell clones at the genomic level is expanding our understanding of their role in diseases such as rheumatoid arthritis (RA) and multiple sclerosis (MS). We have been carrying out genotypic analysis by PCR of hypoxanthine phosphoribosyltransferase (hprt) mutations in these cells. Mutant T cells in the population can be cloned on the basis of their resistance to the cytotoxic drug, 6-thioguanine (6-TG). A difficulty is that the majority of primary human T cells are capable of only limited growth ex vivo, even in the presence of 'feeder' cells. PCR analysis of DNA from such clones is made difficult by the limited number of viable mutant (drug-resistant) T

cells and the large number of dead (drug-sensitive) mononuclear cells and feeder cells. DNA from the 'dead' cells remains sufficiently intact for many weeks in culture and can represent a significant source of background in PCR analysis. Here we describe a method employing hypotonic shock and micrococcal nuclease that reliably eliminates non-viable 6-TG-sensitive cells, allowing the study of the hprt gene in <200 T cells by PCR.

Granziero, L., P. Nelboeck, et al. (1997). "Baculovirus cDNA libraries for expression cloning of genes encoding cell-surface antigens." Journal of Immunological Methods **203**(2): 131.

<http://www.sciencedirect.com/science/article/B6T2Y-3PH8M86-F/2/bd85a9c07dafac3b297b84f457bb4a13>

We describe a method for the production of baculovirus-based cDNA libraries. By staining with monoclonal antibodies, single positive cells can be sorted and the virus encoding for the surface epitope can be isolated by limiting dilution. We have used this method to isolate cDNAs encoding several cell-surface antigens.

Guttieri, M. C., C. Bookwalter, et al. (2000). "Expression of a human, neutralizing monoclonal antibody specific to Puumala virus G2-protein in stably-transformed insect cells." Journal of Immunological Methods **246**(1-2): 97.

<http://www.sciencedirect.com/science/article/B6T2Y-41S4SCM-B/2/4cff1fbc5c2fdd8ab8c528110841acea>

We cloned the heavy- and light-chain antibody genes of a human X (human x mouse) trioma secreting a neutralizing, IgG monoclonal antibody to the G2-protein of Puumala virus. The antibody genes were inserted separately into plasmid transfer vector pIEI-4 such that the genes were under control of the baculovirus immediate early gene promoter, IEI. *Trichoplusia ni* (TN) cells were co-transfected with these constructs and a selection plasmid containing a neomycin-resistance gene. Cloned transformants expressing the IgG monoclonal antibody were identified by ELISA of transfected TN cell culture supernatants. TN cell lines were established from four selected clones, of which one was chosen for detailed analysis. Specificity of the insect cell-expressed human antibody was determined by ELISA with Puumala virus-infected cell lysates and by immune-precipitation of radiolabeled Puumala virus proteins. The expressed IgG retained the ability to neutralize Puumala virus in plaque-reduction neutralization assays. Using competitive polymerase chain reaction methods, multiple copies of integrated heavy- and light-chain antibody genes were detected in the insect cell genome. The transformed insect cells were stable and continuously expressed biologically active IgG. We conclude that this methodology provides an alternative eukaryotic source for the generation of human antibodies.

Hein, W. R., T. Barber, et al. (2004). "Long-term collection and characterization of afferent lymph from the ovine small intestine." Journal of Immunological Methods **293**(1-2): 153.

<http://www.sciencedirect.com/science/article/B6T2Y-4D97WW4-1/2/1bfc1c1ee17cd5d7603cce4def7f70ec>

Reliable methods for long-term collection of afferent lymph draining from the small intestine of sheep are described and validated. The procedure was used successfully in normal sheep, in animals infected experimentally with the parasitic intestinal nematode *Trichostrongylus*

colubriformis and in animals infected naturally with *Mycobacterium avium* subsp. paratuberculosis, the causative agent of Johne's disease. Our approach enabled afferent lymph draining from the small intestine to be collected continuously for up to 4 months, without any detrimental effects on the animals. Based on cytokine gene expression profiles of afferent intestinal lymph cells, the two infections induced contrasting regional immune responses, namely, Th2-type immunity in the case of *T. colubriformis* infection and Th1-type immunity in natural cases of Johne's disease. Some immune parameters differed markedly between the two disease models, highlighting the potential value of this approach to gain real-time insights into distinctive host-pathogen interactions as they occur in vivo within the regional immune system of the gastrointestinal tract.

Huang, S.-K., D. M. Essayan, et al. (1994). "Detection of allergen- and mitogen-induced human cytokine transcripts using a competitive polymerase chain reaction." Journal of Immunological Methods **168**(2): 167.

<http://www.sciencedirect.com/science/article/B6T2Y-476KR7K-55/2/8bf55c556b4cf5c532d3984eabffb86c>

Human cytokines, IL-4, IL-5, and IFN- γ play an important role in the regulation of IgE synthesis and atopic diseases. In this communication, we describe the development of a quantitative assay of steady-state cytokine mRNAs (IL-4, IL-5, and IFN- γ) from a variety of cell sources, including peripheral blood mononuclear cells (PBMCs) stimulated with either a mitogen (PHA) or ragweed pollen allergen extract, and cells from allergen-challenged inflammatory sites. Quantitative analysis of IL-5, IL-4 and IFN- γ transcripts was achieved by a competitive reverse transcription-polymerase chain reaction (RT-PCR) technique using internal standard (IS) cRNAs in the presence of specific oligonucleotide primers. Each IS was generated from a plasmid vector containing the respective cytokine cDNA modified by insertion with an SV40-DNA fragment. Both test RNA and IS were reverse-transcribed and subjected to the 'competitive' PCR in the same tube. We first demonstrate the linearity and reproducibility of this technique; second, we apply this competitive PCR assay to analyze quantitatively the expression of IL-4, IL-5, and IFN- γ transcripts in PBMCs before and after stimulation with PHA or crude ragweed allergen. Finally, we analyzed cells isolated from the lung lavage fluids of an atopic subject following allergen challenge, and showed a significant increase of IL-4 and IL-5 transcripts, but not IFN- γ , in the allergen-challenged site when compared to the control. This technique of PCR quantitation provides an easy and efficient tool to study the expression of cytokine genes in allergic inflammatory diseases.

Jena, P. K., A. H. Liu, et al. (1996). "Amplification of genes, single transcripts and cDNA libraries from one cell and direct sequence analysis of amplified products derived from one molecule." Journal of Immunological Methods **190**(2): 199.

<http://www.sciencedirect.com/science/article/B6T2Y-3VXJJDJ-6/2/e7e482b90d1d7358116b3ee9302247ab>

We report a procedure to generate and amplify cDNA libraries and to amplify and sequence genes and single RNA transcript molecules from the same cell without cloning. An absence of cloning steps minimizes potential sources of contamination, which can be especially problematic when working at the single cell level. Potential contamination is further reduced by an absence of any purification step prior to PCR amplification. Amplifications are designed to minimize the production of aberrant molecules in favor of full-length products, which is especially advantageous when generating cDNA libraries. Genes are amplified from isolated single nuclei, which are segregated from cytoplasmic lysates by microcentrifugation. Specific cDNA, total cDNA

or both are synthesized from aliquots of the cytoplasmic lysate, and single cDNA molecules are isolated from others of the same species by limiting dilution prior to PCR amplification. In this way, the frequency of amplified products provides for a direct calculation of cDNA copy number by a Poisson analysis. Incorporation errors by Taq DNA polymerase occur at a low frequency and can be eliminated by sequencing independently amplified cDNA molecules from the same cell. Single molecule amplifications provide sufficient material for numerous (~ 150) direct DNA sequencing reactions. The limiting dilution approach also permits sequence information to be obtained from a single cDNA, when highly related transcripts derived from distinct genes are present in the same cell and simultaneously amplified with the same primers. In sum, this method provides for a maximum amount of nucleic acid information to be extracted from one cell. It has a wide range of applications to studies of the immune system where, to a first approximation, each lymphocyte has a unique receptor identity, where specific states of differentiation may be difficult to assess in a mixed cell population, and where cell immortalization procedures are not always possible nor practical.

Klebs, S. H. G., M. W. Hoffmann, et al. (2003). "Detection of H-2 alleles by PCR-RFLP--an alternative to flow cytometry in the screening of transgenic mice." Journal of Immunological Methods **276**(1-2): 197.

<http://www.sciencedirect.com/science/article/B6T2Y-4816W80-1/2/7b4725a7aba1f71722b0905da3fcef36>

An increasing number of experimental models is based on well-defined transgenic mice in medical and biological research. Particularly in settings in which transgenic recombinants are used, a fast and reliable method is needed to screen for a defined H-2 background. For this purpose, flow cytometry with specific monoclonal antibodies is the standard procedure. However, epitopes of closely related rodent strains show only minor variations affecting the production of specific discriminating antibodies. Therefore, cross-reactivity of antibodies against specific major histocompatibility complex (MHC) leads to unreliable results in settings with closely related strains. In need of a method with high reliability, we have designed a screening assay based on polymerase chain reaction (PCR) followed by restriction fragment length polymorphisms (RFLP) to discriminate the MHC class I antigens H-2Kd, -Kb, -Kk, which are sequence variants of the H-2K gene. A part of the mus musculus MHC gene coding for H-2K--covering exons 4 and 5 with MHC-differentiating restriction sites--was amplified. Subsequent restriction digest of the PCR products allows to discriminate the three aforementioned alleles and to identify homozygous as well as heterozygous haplotypes. To distinguish transgenic mice defined by certain MHC backgrounds, the PCR-RFLP method is simple, cost-effective, specific, and reliable and can be used independently or in addition to other methods in any laboratory.

Kotake, S., J. H. R. Schumacher, et al. (1996). "A simple nested RT-PCR method for quantitation of the relative amounts of multiple cytokine mRNAs in small tissue samples." Journal of Immunological Methods **199**(2): 193.

<http://www.sciencedirect.com/science/article/B6T2Y-3W2XNM3-C/2/69e89ff57295a77936e0385298f4dc41>

It is difficult to quantitate cytokine mRNA profiles in small human tissue specimens obtained by a needle biopsy, even using standard RT-PCR methods, because the amount of mRNA in the specimens is very small. To address this problem, we developed highly sensitive, quantitative, nested RT-PCR techniques to evaluate the expression of multiple cytokine mRNAs in synovial specimens obtained by needle biopsy. To reduce effects of variation of initial RNA concentrations, cDNA from each target RNA sample was normalized, using a simplified

competitive PCR method, to the levels of [beta]-actin cDNA. The first and the second (nested) PCR were performed in the same tube to prevent contamination. The number of PCR-product bands, evident on polyacrylamide gel electrophoresis, was used to quantitate the relative amounts of target cDNA. Using our methods, it was possible to evaluate, in a single synovial tissue specimen obtained by needle biopsy, the relative amounts of mRNAs for 10 cytokines (TNF-[alpha], IL-1[beta], IL-2, IL-4, IL-6, IL-10, IL-12 p40, IL-13, IL-15, IFN-[gamma]) and CD3 [delta] chain. Our methods are particularly valuable if there are multiple target mRNAs, numerous samples, or if the amounts of mRNAs are limited. The methods are applicable to a wide variety of tissues and target mRNAs.

Kramer, K. (2002). "Synthesis of a group-selective antibody library against haptens." Journal of Immunological Methods **266**(1-2): 209.

<http://www.sciencedirect.com/science/article/B6T2Y-45TTVWR-5/2/588d46538d72d8569f5988a74b6ad631>

A generic strategy is described for the generation of libraries comprising hapten-selective antibody genes against a group of structurally related low molecular weight target molecules. Hapten antibody libraries are frequently suffering from high background levels of irrelevant antibody genes as a consequence of the immunization, where the small non-immunogenic target molecule is coupled to a large immunogenic carrier protein. In order to elevate the percentage of hapten-specific genes in the library, B cells harboring antibody genes against the group of triazine herbicides were enriched from 21 individual splenocyte populations by means of immunomagnetic separation (IMS). IMS utilizes the specific binding of membrane-associated immunoglobulin receptors on the B cell surface to hapten-coated paramagnetic beads. The variable genes of the specifically enriched subpopulation were cloned into a phagemid vector. The corresponding library yielded up to 75% triazine binding antibody clones after three rounds of phage selection. At least half of these antibodies (abs) were displaceable by triazines resulting in quantitative assays with nanomolar sensitivities. In contrast, no displaceable clone was obtained at the same selection level in a control library, where IMS was omitted. Due to the elevated percentage of relevant antibody genes, the library can be utilized either for the direct isolation of functional antibodies against various triazine herbicides or as group-specific gene source for evolutionary antibody optimization.

Kruse, N., M. Pette, et al. (1997). "Quantification of cytokine mRNA expression by RT PCR in samples of previously frozen blood." Journal of Immunological Methods **210**(2): 195.

<http://www.sciencedirect.com/science/article/B6T2Y-3SDC31Y-8/2/936b9b326cc81cea002df79555ac6838>

In order to facilitate cytokine mRNA detection in blood cells, we have developed a highly reproducible and easily performed RNA isolation method for use with whole blood. Previously frozen human whole blood samples were lysed in guanidine thiocyanate solution to isolate total RNA. After reverse transcription a PCR method was applied to detect [beta]-actin and cytokine mRNA expression (interleukin-(IL)2, IL4, IL10, tumor necrosis factor alpha (TNF[alpha]) and interferon gamma (IFN[gamma])). The presence of cDNA was confirmed by agarose gel electrophoresis and quantitated on-line using sequence-specific fluorochrome labeled internal oligonucleotide probes. This quantitative method is based on the cleavage of fluorescent dye labeled probes by the 5'->3' endonuclease activity of the Taq DNA polymerase during PCR and measurement of fluorescence intensity by a Sequence Detector System. The signal generated was directly proportional to the starting copy number of target molecules in the sample over 6 log concentrations and quantitative analysis of cDNA concentrations was performed in comparison to

[beta]-actin or cytokine cDNA standards. mRNAs coding for [beta]-actin and TNF[alpha] were readily detectable in cDNAs prepared from the whole blood of eight healthy donors, while the other cytokines were expressed in lower amounts (IFN[gamma], IL10) or were undetectable (IL2, IL4). The assay described is highly reproducible, requires no post PCR manipulation of the amplicons and permits the analysis of several hundred PCR reactions per day. Using this method it is possible to detect and quantify cytokine mRNA expression reliably in small amounts of previously frozen blood even after storage of samples for at least several months.

Lai, J.-P., S. D. Douglas, et al. (1999). "Quantification of substance P mRNA in human mononuclear phagocytes and lymphocytes using a mimic-based RT-PCR." Journal of Immunological Methods **230**(1-2): 149.

<http://www.sciencedirect.com/science/article/B6T2Y-3Y8N90D-H/2/d74bda068a31ad7384a9fb9ad56ce444>

We have recently demonstrated that human monocytes and lymphocytes express the substance P (SP) gene at both the mRNA and protein level [Ho, W.Z., Lai, J.P., Zhu, X.H., Uvaydova, M., Douglas S.D., 1997. Human monocytes and macrophages express substance P and neurokinin-1 receptor. *Journal of Immunology*, 159, p. 5654; Lai, J.P., Douglas, S.D., Ho, W.Z., 1998. Human lymphocytes express substance P and its receptor. *Journal of Neuroimmunology*, 86, p. 80; Lai, J.-P., Douglas, S.D., Rappaport, E., Wu, J., Ho, W.-Z., 1998. Identification of a delta isoform of preprotachykinin mRNA in human mononuclear phagocytes and lymphocytes. *Journal of Neuroimmunology*, 91, p. 121]. Using RT-PCR assay with several specific human SP primer pairs, we were able to differentiate four isoforms of preprotachykinin (PPT-A, the SP precursor) mRNA transcripts on ethidium bromide-stained agarose gels and clone the PCR amplified cDNA of the four isoforms ([alpha], [beta], [gamma], and [delta]) of the PPT-A gene. In an effort to quantitatively measure PPT-A mRNA levels, we have developed a mimic-based RT-PCR assay to analyze total PPT-A mRNA levels in human monocytes and lymphocytes. We designed a specific human SP primer pair (HSP4/HSP3) to amplify a single fragment of cDNA derived from all four isoforms of PPT-A mRNA transcripts, with a sensitivity of 120 molecules per reaction. Thus the PPT-A mRNA transcripts in an unknown sample can be quantitatively analyzed using the mimic-based RT-PCR. The accuracy and reproducibility of this assay were confirmed by the plasmids containing [alpha], [beta], [gamma] and [delta] cDNA inserts and by in vitro synthesized mRNA from a plasmid containing [beta] isoform cDNA insert. Our data indicate that the SP mimic-based RT-PCR assay has potential advantages in studies of SP levels in a variety of human cells as well as in clinical specimens.

Lilley, G. G., O. Dolezal, et al. (1994). "Recombinant single-chain antibody peptide conjugates expressed in *Escherichia coli* for the rapid diagnosis of HIV." Journal of Immunological Methods **171**(2): 211.

<http://www.sciencedirect.com/science/article/B6T2Y-476D471-HJ/2/24fb8737afddf906d0addd04fb5a02e3>

Recombinant single chain Fv (scFv) antibody fragments can form the basis of a rapid, whole-blood diagnostic assay. The scFv described in this study is derived from a monoclonal antibody which has a high affinity for glycophorin A, an abundant glycoprotein on the human red blood cell membrane surface. The prototype reagent built around the scFv was designed to detect, in whole blood samples, the presence of antibodies that have arisen through infection with a foreign organism such as human immunodeficiency virus. The scFv was composed of the antibody heavy-chain variable domain (Vh) joined by a 15 residue linker-(GGGGS)³- to the light-chain variable domain (Vl) terminated by either a C-terminal octapeptide tail (FLAG) or a 35 amino acid segment from the gp41 surface glycoprotein of HIV-1. Constructs were cloned into a *Escherichia*

coli expression vector, pHFA, and expressed in a soluble form into culture supernatant. The product retained anti-glycophorin activity which could be detected directly in culture supernatants by ELISA. Furthermore, the scFv-epitope fusion functioned efficiently in the whole blood agglutination assay and was able to distinguish between HIV-1 positive and negative sera.

Lim, A., V. Baron, et al. (2002). "Combination of MHC-peptide multimer-based T cell sorting with the Immunoscope permits sensitive ex vivo quantitation and follow-up of human CD8+ T cell immune responses." Journal of Immunological Methods **261**(1-2): 177.

<http://www.sciencedirect.com/science/article/B6T2Y-451NPPT-1/2/8d59b4e3613d27d24746e53ace1b5b55>

Identification of MHC-restricted antigens and progress in the induction and control of adaptive cytotoxic immune responses have led to renewed interest in immunotherapy as a treatment for severe pathologies such as cancer and autoimmune diseases. Reliable procedures for detecting and monitoring T cell responses induced by the treatment throughout a clinical trial are needed in order to design rational protocols with increased efficiency. We have attempted to develop such a procedure by combining T cell sorting using HLA-peptide complexes multimerized on magnetic beads together with the quantitative Immunoscope approach. Once a recruited patient has been typed for HLA and target antigens, relevant HLA-peptide multimers can be selected and used for sorting specific peripheral T cells prior to any treatment and at the peak of the expected response to treatment. Clonotypic primers specific for the TCR rearrangements of the specific T cell clones can then be designed and used for measuring the frequency of their TCR transcripts by quantitative PCR on blood samples or T cell subsets throughout the trial. In reconstruction experiments as well as in samples from one rheumatoid arthritis patient, we were readily able to detect and follow several T cell clones with a frequency as low as 10^{-5} among CD8+ T cells. The main advantages of this procedure over other currently available assays are that it does not require any assumptions on the functional status of the specific T cells and it permits the monitoring of individual T cell clones whose phenotypic shift can thus be evaluated.

Litton, M. J., B. Sander, et al. (1994). "Early expression of cytokines in lymph nodes after treatment in vivo with Staphylococcus enterotoxin B." Journal of Immunological Methods **175**(1): 47.

<http://www.sciencedirect.com/science/article/B6T2Y-476MXWH-16H/2/9b850b45027b1664267ef98f2d4f3704>

Excessive cytokine expression induced by superantigen may be one aspect of the pathophysiology associated with Gram positive bacteremia. We have undertaken a study of the kinetics of cytokine production in lymph nodes obtained from in vivo Staphylococcus enterotoxin B (SEB) treated animals. This study was designed to evaluate the short term cytokine profile observed using immunohistochemistry (IHC) in BALB/c mice injected intraperitoneally (i.p.). The observed immunohistochemical kinetic profiles were corroborated using reverse transcription-polymerase chain reaction (RT-PCR) RNA analysis. We report here that TNF, IL-2, and IFN- γ are the principal cytokines which were detected within hours of SEB administration, and that other cytokines such as IL-3, IL-4, IL-5, IL-6, IL-10, GM-CSF and M-CSF were undetectable. TNF and IL-2 appeared very early following SEB priming, and were observed by 1 h. IFN- γ which appeared later (maximally at 14 h) was produced predominantly by CD8+ cells. In contrast, the TNF and IL-2 were produced primarily by CD4+ cells. Identical results were obtained by IHC and RT-PCR; the kinetics of mRNA expression slightly preceded the appearance of protein. The TNF and IFN- γ staining patterns observed in lymph node sections were indicative of Golgi-localized cytokine. The IL-2 staining pattern observed in lymph node sections was distinctive, covering a significant local area of cells. This local regional concentration of IL-2,

which may result from cytokine attached to extracellular binding components, may be an important aspect of the activation phase of a developing immune response. Rapid induction and excessive cytokine production elicited by superantigen in vivo, may ultimately help to explain the shock and death associated with SEB.

Loseke, S., E. Grage-Griebenow, et al. (2003). "Differential expression of IFN-[alpha] subtypes in human PBMC: evaluation of novel real-time PCR assays." Journal of Immunological Methods **276**(1-2): 207.

<http://www.sciencedirect.com/science/article/B6T2Y-483BN53-1/2/216383c3f6377e8658a3b112f8674ff9>

Studies of the human IFN-[alpha] subtype system have been hampered by the lack of efficient procedures to quantify and differentiate the expression of the highly homologous IFN-[alpha] subtypes. Here we evaluate four novel real-time PCR assays for the specific detection and quantification of IFN-[alpha] mRNA for the subtypes [alpha]2, [alpha]6, [alpha]8 and [alpha]1/13 in a combined assay in human peripheral blood mononuclear cells (PBMC). This included (a) the selection of [beta]-glucuronidase (GUS) as a suitable housekeeping gene for relative quantification; (b) verification of the specificity by using human DNA of different IFN-[alpha] subtypes; and (c) comparison of the amplification efficiencies among the different assays. This highly sensitive method allows the detection of low-level, constitutive IFN-[alpha] mRNA and shows differences in the composition of constitutive IFN-[alpha] subtypes compared to other cell types (HeLa and HEp-2). The in vitro stimulation of PBMC with Newcastle disease virus (NDV), Respiratory syncytial virus (RSV) or an inactivated Herpes simplex (HSV) preparation leads to the transcriptional induction of all IFN-[alpha] subtypes investigated but to different expression levels. Among the subtypes detected, IFN-[alpha]13/1 and [alpha]2 are the major transcripts followed by [alpha]8, and finally [alpha]6 as a minor transcribed subtype. Time-kinetics of IFN-[alpha] transcriptional activation also revealed variations in the course of IFN-[alpha] transcription between NDV, RSV or HSV. The data obtained from the real-time PCR assays correlated well with IFN-[alpha]2 protein release. In conclusion, we have demonstrated the suitability and reliability of new real-time PCR assays for the rapid and efficient analysis of IFN-[alpha] subtype expression.

Manfras, B. J., W. A. Rudert, et al. (1997). "Analysis of the [alpha]/[beta] T-cell receptor repertoire by competitive and quantitative family-specific PCR with exogenous standards and high resolution fluorescence based CDR3 size imaging." Journal of Immunological Methods **210**(2): 235.

<http://www.sciencedirect.com/science/article/B6T2Y-3SDC31Y-D/2/f610b6d3366057ae3575e39879797334>

The characterization of the human T-cell receptor (TCR) repertoire in various physiological and pathological conditions has become an important tool in studies of the immune response. Therefore, a number of PCR based strategies for the semiquantitative analysis of the TCR repertoire have been described. Family specific amplification of TCR cDNA has been employed in a number of studies often with contradictory results. We have developed a strategy utilizing exogenous standards with homologous primer binding sites for the quantitative analysis of the [alpha]/[beta] T-cell receptor repertoire. This system allows the detection of even minute differences in T-cell populations based on quantitative PCR (Q-PCR) and competitive PCR (C-PCR). Results presented here demonstrate that expansions of T-cell subsets as defined by the specificity of the variable gene segments can be readily monitored when exceeding 1% of the total repertoire. In addition, the proposed method reveals direct information of CDR3 size heterogeneity and can be used to estimate the T-cell repertoire complexity and monitor clonal

expansions. We discuss variables such as cell number and experimental conditions influencing accuracy and reproducibility of the analyses. We have used this protocol based on non-radioactive techniques for characterization of the fine specificity of the T-cell repertoire in peripheral and organ-infiltrating T-lymphocytes. The analyses revealed information about polyclonal or clonal expansion of T-cells in vivo and in vitro following various stimuli such as superantigenic stimulation of T-cell subsets as well as antigen-driven shaping of the [alpha]/[beta] T-cell repertoire in autoimmune and infectious diseases.

McCarthy, B. J. and A. S. Hill (2001). "Altering the fine specificity of an anti-Legionella single chain antibody by a single amino acid insertion." Journal of Immunological Methods **251**(1-2): 137.

<http://www.sciencedirect.com/science/article/B6T2Y-42PBYP5-G/2/ea0d4902cf877753f22ecc04b91c4fd3>

Antibody engineering provides the potential to clone and manipulate antibody genes to produce fragments with altered specificity. We have produced an anti- Legionella single chain fragment with broader specificity towards Legionella serotypes than the parent monoclonal antibody. Using this relationship between the parent monoclonal and the recombinant antibody derived from it as a model, we attempted to identify those residues responsible for this change in fine specificity. Sequence analysis of this recombinant antibody revealed the deletion of a conserved residue, Asp101, in the CDR-H3 region. Using site-directed mutagenesis, we have created a mutant form of this single chain fragment with an aspartic acid insertion mutation at position 101 of the antibody heavy chain. This mutant scFv demonstrates improved specificity compared to the wild-type recombinant antibody, indicating an important role for Asp101.

Morimoto, K., M. J. Schnell, et al. (2001). "High level expression of a human rabies virus-neutralizing monoclonal antibody by a rhabdovirus-based vector." Journal of Immunological Methods **252**(1-2): 199.

<http://www.sciencedirect.com/science/article/B6T2Y-42WYG14-R/2/f1df8a7b30af3370bbd317029adc3f81>

Humans exposed to rabies virus must be promptly treated by passive immunization with anti-rabies antibody and active immunization with rabies vaccine. Currently, antibody prepared from pooled human serum or from immunized horses is utilized. However, neither of these reagents are readily available, entirely safe, or consistent in their biological activity. An ideal reagent would consist of a panel of human monoclonal antibodies. Such antibodies are now available, their only drawback being the cost of production. Using recombinant technology, we constructed a rabies virus-based vector which expresses high levels (~60 pg/cell) of rabies virus-neutralizing human monoclonal antibody. The vector is a modified vaccine strain of rabies virus in which the rabies virus glycoprotein has been replaced with a chimeric vesicular stomatitis virus glycoprotein, and both heavy and light chain genes encoding a human monoclonal antibody have been inserted. This recombinant virus can infect a variety of mammalian cell lines and is non-cytolytic, allowing the use of cell culture technology routinely employed to produce rabies vaccines.

Mougin, B., P. Garnero, et al. (2001). "A routine assay for the direct analysis of HLA-DR-related shared epitope and B27 alleles in chronic inflammatory arthritis." Journal of Immunological Methods **256**(1-2): 47.

<http://www.sciencedirect.com/science/article/B6T2Y-43RVDJ7-5/2/ed00cb685eb8f12d92d948dd88650dbe>

Knowledge of the genetic background of patients with inflammatory arthritis may be useful for disease management. The main markers are the HLA-DR-associated Shared Epitope (SE) for Rheumatoid Arthritis (RA) and HLA-B27 for ankylosing spondylitis. We have developed a simple molecular biology-based test to provide this essential information. HLA targets are amplified by polymerase chain reaction (PCR), then simultaneously analyzed using 16 individual hybridization reactions in two 8-well ELISA strips with colorimetric detection. Concordance was evaluated using a cohort of RA patients with known genotype. Using this new assay, 100% concordance was observed with conventional genotyping in RA patients both for HLA-DR SE and B27 genotypes. Seventy-three percent of the patients with destructive RA had at least one susceptible allele within SE, compared to 38% of those patients with non-destructive disease. This new assay, which requires minute amount of blood, could be used to determine the genetic background of inflammatory arthritis, particularly in non-specialized settings and for large-scale clinical trials.

Okochi, E., T. Iwahashi, et al. (1995). "Establishment and evaluation of MRK16-magnetic cell sorting assays for detecting low expression of multidrug resistance P-glycoprotein using human leukemia cell lines and peripheral blood cells from healthy donors." Journal of Immunological Methods **187**(1): 127.

<http://www.sciencedirect.com/science/article/B6T2Y-3YB516Y-1W/2/c54687020eb0488e43f8555492e6c1da>

Two types of magnetic cell sorting assays, termed MRK16-MACS and MRK16-MACS-FACS, have been established to detect low expression level of P-glycoprotein (P-gp) using a monoclonal antibody MRK16, which recognizes a cell surface epitope of P-gp. With K-562 and U-937 cell lines, which are known to express low levels of P-gp and hence routinely used as negative control cell lines in conventional flow cytometry, both assays gave significantly positive reactivities indicating improved specificity and sensitivity of these assays. The findings in the dilution test, where P-gp-positive cells were added to P-gp-negative cells at various ratios, demonstrated that the MRK16-MACS assay is quantitative and capable of detecting small numbers of P-gp-positive cells as few as 2.5% of the total cells tested. Furthermore, specific enrichment of P-gp-expressing cells in magnetic cell sorting assays was verified by reverse transcription-polymerase chain reaction (RT-PCR) analysis and functional assay for P-gp with Rhodamine 123. The availability of such magnetic cell sorting assays offer an approach to quantitate low level of P-gp expression.

Pichyangkul, S., P. Saengkrai, et al. (2001). "Isolation and characterization of rhesus blood dendritic cells using flow cytometry." Journal of Immunological Methods **252**(1-2): 15.

<http://www.sciencedirect.com/science/article/B6T2Y-42WXXG14-2/2/e9822a5edc45506a37858dcacb627cfa>

Recognition of dendritic cells (DCs) as initiators and modulators of immune responses and growing use of rhesus monkeys for the preclinical optimization of vaccine formulations prompted characterization of the phenotype and function of isolated rhesus peripheral blood DCs. We developed a flow cytometric method to directly identify and isolate DCs from rhesus peripheral blood whereby a T cell depleted population negative for CD3, CD14, CD16 and CD20 but positive for CD83 yielded a cell population with surface markers, morphology, and a cytokine profile similar to human myeloid DCs. Rhesus blood DCs were more effective than monocytes and B

cells in mixed lymphocyte reactions and in the presentation of recombinant malaria blood stage antigen MSP-1(42) to autologous T cells. The ability to isolate rhesus blood DC from peripheral blood should be a useful tool for immunological investigations.

Snowwhite, I. V., W. E. Jones, et al. (2002). "Comparative analysis of methods for collection and measurement of cytokines and immunoglobulins in cervical and vaginal secretions of HIV and HPV infected women." Journal of Immunological Methods **263**(1-2): 85.

<http://www.sciencedirect.com/science/article/B6T2Y-45F92S9-1/2/893b8b34f2070014867ec417719efc54>

The goal of these studies was to distinguish which of two techniques [cervicovaginal lavage (CVL) and cervical wick (SS)] is the optimal collection method for the measurement of the local immunological response in human papillomavirus (HPV) and HIV infected women. The following parameters were measured in 24 paired samples from 15 women (9 HIV+, 6 HIV-): total protein, immunoglobulin levels, HPV-specific antibodies, and Th1-Th2 cytokines. In addition, relative mRNA levels from CVL cell pellets were compared to protein levels from CVL supernatants. The total protein (2-fold) and IgG concentration (10-fold) are higher in the SS samples, were reproducible (%CVPr>0.28, P18) failed to yield reproducible results for the cytokine assays as compared to the CVL (%CV<5.0). Furthermore, no correlations were found between relative mRNA levels from CVL cell pellet and cytokine protein levels in CVL supernatants. The CVL sample's superior reproducibility in the cytokine assays makes this the better collection method. In addition, cytokine protein level's failure to correlate with mRNA suggests tight regulation of cytokine genes or production from a different cell population.

Tanha, J., G. Dubuc, et al. (2002). "Selection by phage display of llama conventional VH fragments with heavy chain antibody VHH properties." Journal of Immunological Methods **263**(1-2): 97.

<http://www.sciencedirect.com/science/article/B6T2Y-458PF43-2/2/dc88d7722b7bc8b90caf13398e5f3d96>

A llama single domain antibody (dAb) library designed and constructed to contain only heavy chain antibody variable domains (VHHs) also contained a substantial number of typical conventional antibody heavy chain variable sequences (VHs). Panning the library against two carbohydrate-specific antibodies yielded anti-idiotypic dAbs and enriched solely for sequences from the VH subpopulation of the library. The conventional antibody origin of these VHs was confirmed by using oligonucleotide probes, specific for the enriched VHs, to identify the parental sequences in the message employed in library construction. Surprisingly, these VH dAbs, which are produced in high yield in *Escherichia coli*, are highly soluble, have excellent temperature stability profiles and do not display any aggregation tendencies. The very close similarity of these molecules to human VHs makes them potentially very useful as therapeutic dAbs.

Taylor, K. M., J. Paul Luzio, et al. (1994). "A method for in vitro synthesis of unglycosylated recombinant complement component C9." Journal of Immunological Methods **167**(1-2): 129.

<http://www.sciencedirect.com/science/article/B6T2Y-476M0BJ-36R/2/485e59d1d72eb25cfa1a113b06daa5ba>

A method for in vitro synthesis of human complement component C9 has been established in

order to generate unglycosylated normal and mutant proteins without the need to sub-clone. One or two step polymerase chain reaction (PCR) was used to add the T7 RNA polymerase promoter and introduce multiple mutations within the cDNA. The cDNA was then transcribed by T7 RNA polymerase and the mRNA translated in a rabbit reticulocyte lysate or wheat germ system. Successful synthesis was confirmed by: the correct size of PCR product DNA on agarose gel electrophoresis, incorporation of [α]- ^{32} P]UTP into mRNA, and formation of [^{35} S]methionine-labelled protein of the correct molecular mass for full length C9. The wheat germ extract generated up to 1.5 [μ]g of recombinant C9. This unglycosylated C9 had at least 10% of the haemolytic activity of native C9. Unglycosylated C9 polymerised more readily than the native protein. This spontaneous polymerisation was increased by removal of the first 23 amino acids or mutating two cysteines at positions 33 and 36. This therefore provides a rapid method for screening the effect of multiple mutations on the biological activity and polymerisation of pore forming proteins.

Theilgaard-Monch, K., J. Cowland, et al. (2001). "Profiling of gene expression in individual hematopoietic cells by global mRNA amplification and slot blot analysis." Journal of Immunological Methods **252**(1-2): 175.

<http://www.sciencedirect.com/science/article/B6T2Y-42WYG14-N/2/1ed418ccb508e49b8054feb7457f076>

The pattern of expressed genes defines the structure and functional status of cells. Currently, most methods used in gene expression studies depend on large numbers of cells. Thus, their application may be hampered by the heterogeneity of cell populations, and by the low numbers of cells obtainable from in vivo sources. Such drawbacks may be overcome by methods suitable for the profiling of gene expression at the single cell level. We studied whether polymerase chain reaction (PCR) products synthesized from individual cells by global amplification of messenger RNA (mRNA) were suitable as probes for gene expression analysis. For this purpose, cells were subjected to reverse transcription and PCR using sequence independent primers (SIP RT-PCR). The resultant cDNA products were radiolabeled and hybridized to cDNA clones arrayed on a nylon membrane by vacuum slot blotting (a method referred to as slot blot analysis). The SIP RT-PCR procedure was reproducible and allowed the detection of twofold changes in input RNA copies per cell (range: 80-10,000 copies of an in vitro transcribed poly(A)-tailed RNA/cell). Analysis of total RNA and amplified cDNA, obtained from neutrophil granulocytes and the promyelocytic HL-60 cell line, demonstrated comparable gene expression profiles as measured by Northern blot and slot blot analysis. Slot blot analysis of HL-60 cells indicated that individual cells from an apparently homogenous population have varying expression of specific transcripts, which all contribute to the mRNA phenotype of their population. Interestingly, the genes that were detected in some but not all individual HL-60 cells were those found to peak within 2 days of retinoic acid-induced granulocytic differentiation. This study demonstrates the potential of cDNA, synthesized from individual cells by global amplification of mRNA, as probes for cDNA arrays.

Tseng, L.-H., P.-J. Chen, et al. (2002). "Simultaneous genotyping of single nucleotide polymorphisms in the IL-1 gene complex by multiplex polymerase chain reaction-restriction fragment length polymorphism." Journal of Immunological Methods **267**(2): 151.

<http://www.sciencedirect.com/science/article/B6T2Y-460DMW3-2/2/2be180e41b938e530735feaffa93c1b9>

The interleukin-1 (IL-1) gene complex consists of the IL-1[α], IL-1[β] and IL-1 receptor antagonist genes. Single-nucleotide polymorphisms (SNP) in all three genes have been associated with human diseases. In this study, primers containing mismatches at 1-3 nucleotide

positions were designed to incorporate a restriction site for endonuclease AlwNI or XcmI in the presence of allele-specific nucleotides at the polymorphic positions. Based on this technique, a simple and robust multiplex polymerase chain reaction/restriction fragment length polymorphism (multiplex PCR/RFLP) assay was developed to determine simultaneously three to four informative SNPs (IL-1[β]/+3954, IL-1[β]/-511 and IL-1Ra/9261 or IL-1[α]/-889, IL-1[β]/-31, IL-1[β]/5810 and IL-1Ra/11100 SNPs) in the IL-1 gene complex.

Udby, L., J. B. Cowland, et al. (2002). "An ELISA for SGP28/CRISP-3, a cysteine-rich secretory protein in human neutrophils, plasma, and exocrine secretions." Journal of Immunological Methods **263**(1-2): 43.

<http://www.sciencedirect.com/science/article/B6T2Y-45BCSNG-1/2/19928f97a294f1e258e796a786fbabf0>

Specific granule protein of 28 kDa (SGP28), also termed cysteine-rich secretory protein 3 (CRISP-3), is a glycoprotein that belongs to a family of cysteine-rich secretory proteins (CRISPs). SGP28 was originally discovered in human neutrophils, but transcripts are widely distributed in exocrine glands (salivary glands, pancreas, and prostate) and also found at lower levels in epididymis, ovary, thymus, and colon. The function of SGP28/CRISP-3 is not yet known. Similarities to pathogenesis-related proteins in plants and the expression in neutrophils and exocrine glands suggest that SGP28/CRISP-3 may play a role in innate host defense. We describe here the production of a recombinant, C-terminally truncated form of CRISP-3 (rCRISP-3[Δ]) and the generation of polyclonal antibodies against rCRISP-3[Δ] that are useful in immunoblotting and immunocytochemistry. We present a specific, accurate, and reproducible enzyme-linked immunosorbent assay (ELISA) for the measurement of CRISP-3 with a detection limit of 2 ng/ml. We further demonstrate the presence of CRISP-3 protein in human plasma (6.3 [μg/ml]), saliva (21.8 [μg/ml]), seminal plasma (11.2 [μg/ml]), and sweat (0.15 [μg/ml]), and describe the coexistence of two different molecular weight forms of CRISP-3, representing an N-glycosylated and a non-glycosylated form of the mature protein.

van Koningsbruggen, S., H. de Haard, et al. (2003). "Llama-derived phage display antibodies in the dissection of the human disease oculopharyngeal muscular dystrophy." Journal of Immunological Methods **279**(1-2): 149.

<http://www.sciencedirect.com/science/article/B6T2Y-48V7RJ0-2/2/e9d09b00f28394b95f8e074381de24cc>

Functional analysis of the estimated 30,000 genes of the human genome requires fast and reliable high-throughput methods to study spatio-temporal protein dynamics. To explore the suitability of heavy-chain antibodies (HCAbs) for studying mechanisms underlying human disease, we used oculopharyngeal muscular dystrophy (OPMD) as a paradigm for the expanding group of protein aggregation disorders that is characterized by subcellular dislocalization and aggregation of mutant protein. OPMD is caused by a moderate alanine expansion in the poly-A binding protein nuclear 1 (PABPN1) and is associated with intranuclear PABPN1 deposition exclusively in muscle. An experimental approach was designed in which the primary sequence of the PABPN1 gene was employed for generating a prokaryotic expression construct that permitted its expression in the host *Escherichia coli*. The purified product was used for immunization of a llama as well as for the selection of an antigen-specific antibody fragment from the derived phage display library. This single-domain antibody was able to recognize the native gene product in mammalian cell lines and in human muscle tissue by immunocytochemical, immunohistochemical and immunoblot analysis. Our results suggest that phage display derived heavy-chain antibodies can be used in proteomics to study the localization and function of hypothetical gene products,

relevant to human disease.

VanderBorgh, A., A. Van der Aa, et al. (1999). "Identification of overrepresented T cell receptor genes in blood and tissue biopsies by PCR-ELISA." Journal of Immunological Methods **223**(1): 47.

<http://www.sciencedirect.com/science/article/B6T2Y-3VM79Y0-5/2/ccb84eff0224f7c7efc71aeb9c261129>

The analysis of T cell receptor variable (TCR V) gene repertoires in blood or tissues may provide important information when studying immunopathological mechanisms. The overexpression of a TCR gene may indicate the expansion of the corresponding T cell subset. In autoimmune diseases, clonally expanded T cell subsets in the affected organs may represent pathogenic lymphocytes. We describe a simple, rapid and sensitive method to determine the TCR AV and BV gene repertoire using a PCR-ELISA method. RNA is extracted from lymphocytes, transcribed to cDNA, which is then used as a template for PCR with 19 different TCR AV gene and 20 BV gene specific primers as the forward primer, and a digoxigenin (DIG) labeled AC/BC primer as the reverse primer. The DIG labeled PCR amplicons are hybridized with a fluorescein isothiocyanate (FITC) labeled TCR C region specific probe. Finally, the amplicons are quantified by ELISA using anti-FITC coated microtiter plates, and an anti-DIG conjugated peroxidase. Although PCR-ELISA cannot accurately quantify the expression level of a given TCR gene, overrepresented TCR V genes are easily identified by comparing the relative expression levels of each individual V gene in the total V gene repertoire. We demonstrate that this technique can be used to determine TCR profiles in blood and tissue samples containing as few as 50,000 T cells. In combination with CDR3 fragment size analysis, this method is an efficient tool to identify clonally expanded T cell subsets in the synovial biopsies of rheumatoid arthritis patients.

Vidarsson, G., J. G. J. van de Winkel, et al. (2001). "Multiplex screening for functionally rearranged immunoglobulin variable regions reveals expression of hybridoma-specific aberrant V-genes." Journal of Immunological Methods **249**(1-2): 245.

<http://www.sciencedirect.com/science/article/B6T2Y-42D82CM-T/2/1456548fa6dee966be9f4c58b48483b3>

Modification of antibody effector functions is commonly performed by chimerization or humanization. Cloning of antibody variable regions from hybridomas represents a first step that is frequently hampered by the expression of non-functionally rearranged variable regions in hybridoma cells that originate from MOPC21-derived fusion partners. We now present a simple method to clone functionally rearranged V-genes, based on V-gene-specific multiplex PCR screening. Using this method we document the expression of aberrant V-genes that originate from the original B-cell used for the hybridoma generation, not from the fusion partner, and are -- thus -- hybridoma specific.

Vilarino, N. and J. D. MacGlashan (2005). "Transient transfection of human peripheral blood basophils." Journal of Immunological Methods **296**(1-2): 11.

<http://www.sciencedirect.com/science/article/B6T2Y-4DXBS5T-1/2/e5cb290cea20709daf5d306e3c4599cd>

The human basophil has resisted previous attempts at transient transfection. Basophils were

transfected by nucleoporation and to test whether there was sufficient expression to modify cell function, the cells were transfected with a syk kinase tandem SH2 construct linked to GFP. This approach was taken because in RBL cells and murine mast cells syk kinase is known to play a very early role in signal transduction and previous studies in RBL cells demonstrated that expression of the tandem SH2 domains of syk would inhibit signaling, presumably by competition with endogenous syk for binding to ITAMs. Results from basophil transfections with SH2syk were compared to an empty construct. Basophils were stimulated with anti-IgE antibody and analyzed for single cell changes in cytosolic calcium levels. Basophils expressing the empty GFP construct showed a cytosolic calcium response similar to non-expressing cells. In contrast, basophils expressing the GFP-tandem SH2syk construct, on average, showed an anti-IgE-induced calcium response that was completely ablated. The transfection frequency was 8% (median), with an average viable recovery of 12% (n=18). While the procedure is not benign and is not always successful, these studies indicate that with gating techniques, the human basophil, a non-dividing primary leukocyte, can be transiently transfected to express high enough levels of an inhibitory protein to alter an IgE-mediated response.

Weber-Arden, J., O. M. Wilbert, et al. (1996). "Inverse PCR amplification of low-abundance message of [gamma][delta] T cell receptor genes." Journal of Immunological Methods **197**(1-2): 187.

<http://www.sciencedirect.com/science/article/B6T2Y-3W257R7-M/2/2c2d99ba099e15d76f95a65223648442>

The technique of inverse PCR permits the rapid amplification and identification of unknown DNA segments adjacent to well characterized core regions. In the field of immunology anchored PCR and inverse PCR are useful methods for examining junctional diversity and unknown variable gene segments of rearranged T cell receptor genes. We have applied an improved inverse PCR protocol to study the repertoire of [gamma][delta] T cell receptor genes in the developing thymus of the mouse.

Yau, K. Y. F., M. A. T. Groves, et al. (2003). "Selection of hapten-specific single-domain antibodies from a non-immunized llama ribosome display library." Journal of Immunological Methods **281**(1-2): 161.

<http://www.sciencedirect.com/science/article/B6T2Y-49FXMPV-1/2/070291e39a4dd2c040fe5019d43ebd08>

Picloram-specific variable fragments (VHHs) of heavy chain antibodies (HCAbs) were selected from a naive-llama library using ribosome display technology. A cDNA library of VHHs was constructed from lymphocytes of a non-immunized llama and engineered to allow in vitro transcription and translation. With no stop codons present on the transcripts, trimeric complexes of ribosomes, mRNAs and nascent peptides were produced for affinity selection, i.e. panning. After three cycles of panning, seven different VHHs all belonging to the VHH subfamily 1 were isolated. Following another three cycles of selection, only two of the seven VHHs persisted. A comparison of these two sequences with known sequences in the literature suggests that point mutations may have been introduced into the DNA pool during PCR amplification steps of library construction, panning and/or cloning. Three separate point mutations causing three independent amino acid changes (nonsynonymous mutations) accumulated in the same sequence and enriched throughout the selection protocol, suggesting that these changes confer binding advantages. Surface plasmon resonance (SPR) analysis was used to determine binding kinetics of the two clones (3-1D2 and 3-1F6) representing the two different sets of isolated complementarity determining region (CDR)3s. Measured KDs were 3 and 254 [mu]M, respectively. The results indicate that ribosome display technology can be used to efficiently isolate hapten-specific antibody (Ab) fragments from a naive library and concurrently introduce

diversity to the selected pool thereby facilitating molecular evolution. Ribosome display technology can compensate for the limited diversity of a VHH naive library and provide an unlimited source of affinity-matured immunoactive reagents in vitro.

Objectives. To study the action of factors produced by living *Campylobacter jejuni* (*C. jejuni*) against those present within sonicated and filtrated bacteria on induction of potential cytokines by the human intestinal cell line INT407. **Methods.** We used immunohistochemical technique modified to detect intracellular production of cytokines protein and RT-PCR to read RNA messages for evaluation of de novo cytokine synthesis. **Results.** The data herein display dissociation of cytokine profiles induced on by living *C. jejuni*. Exposure of INT407 cells to 106 live bacteria showed the highest numbers of cytokine producing cells of all examined cytokines. IFN- γ was the highest induced cytokine followed by IL-10, TNF- α and lastly IL-4. Also, abrogation of induction of the proinflammatory cytokines IFN- γ and TNF- α but not the antiinflammatory cytokines IL-4 and IL-10 by sonicated and filtrated bacteria was depicted. At the mRNA level, TNF- α signals were noted in accordance with its protein levels since increased TNF- α mRNA signals were registered only after stimulation with living bacteria. Very low or no induction of TNF- α was registered with non-stimulated cells. **Conclusions.** These results illustrate for the first time a role for factors from living bacteria in directing the immune response towards Th1 type. Characterization of such factors may be essential for future immunotherapeutic interventions during severe bacterial infections.

Ashshi, A. M., P. E. Klapper, et al. (2003). "Detection of human cytomegalovirus, human herpesvirus type 6 and human herpesvirus type 7 in urine specimens by multiplex PCR." Journal of Infection **47**(1): 59.

<http://www.sciencedirect.com/science/article/B6WJT-48JSJH1-1/2/46b03e4f2b4b8c13cc17d86143e26ed7>

Objectives. To develop a sensitive multiplex PCR to detect HCMV, HHV6 and HHV7, to test this PCR on urine specimens sent to the virus diagnostic laboratory and on stored urine samples from HIV-positive patients and their HIV-negative partners and to compare the sensitivity of the multiplex PCR with the diagnostic laboratory's routine service for the detection of HCMV. **Study design.** Primers specific for each of the three viruses were combined in a multiplex PCR that was then optimised for sensitivity. This PCR was applied prospectively to 413 unselected routine urine specimens over a 1 year period and retrospectively to 258 urine specimens from 63 HIV-positive patients and 10 HIV-negative partners. **Methods.** In the prospective study, the multiplex PCR detected 40 specimens positive for HCMV alone, 10 for HHV6, 3 for HHV7 and 3 with a dual infection of HCMV and HHV6. The sensitivity for HCMV was 93.5% by multiplex PCR compared to 28.3% by culture. HHV6 DNA was detected in 6 neonates (2-21 days) and HHV7 DNA in 2

neonates (4 and 20 days). In the retrospective study of HIV patients, HCMV was the most commonly detected virus (55.6%) compared to HHV6 (7.9%) and HHV7 (4.8%). Conclusions. The multiplex PCR was significantly more sensitive than non-DNA based procedures for the detection of HCMV. Urine may be a useful non-invasive specimen for the detection of HHV6 and HHV7 and their presence in neonates suggest perinatal transmission or the possibility of in utero infection.

Bakhiet, M., F. S. Al-Salloom, et al. (2004). "Induction of [alpha] and [beta] chemokines by intestinal epithelial cells stimulated with *Campylobacter jejuni*." *Journal of Infection* **48**(3): 236.

<http://www.sciencedirect.com/science/article/B6WJT-4BDM2K7-1/2/cc5d7040b208975927e4039ca0875a22>

Objectives. To investigate the production of dynamic [alpha] and [beta] chemokines represented by interleukin-8 (IL-8) as [alpha] chemokine and CCL2 (monocyte-chemoattractant protein-1, CCR2 ligand), CCL4 (macrophage-inflammatory protein-1[beta], CCR5 ligand), CCL3 (macrophage-inflammatory protein-1[alpha], CCR1/5 ligand), (CCL5, regulated upon activation, normal T-cell expressed and secreted (RANTES, CCR5 ligand) as [beta] chemokines by the human intestinal cell line INT407 stimulated with factors produced by living *Campylobacter jejuni* (C. jejuni) and those present within sonicated and filtrated bacteria. **Methods.** We used immunohistochemical technique modified to detect intracellular production of cytokines protein and RT-PCR to read RNA messages for evaluation of de novo cytokine synthesis. **Results.** Living bacteria induced increased numbers of IL-8, CCL4 and CCL2 but not CCL3 or CCL5 producing cells. Low numbers of IL-8, CCL4 and CCL2 producing cells were detected with filtrated supernatant compared to living and sonicated bacteria. A non-significant low number of chemokine producing cells was noted when comparing numbers of chemokine producing cells stimulated with living C. jejuni to those stimulated with sonicated bacteria, indicating that the triggering factors involved in stimulation with living bacteria were still active after sonication, but they were largely lost upon filtration. The mRNA signals for IL-8 were noted in conformity with its protein levels as increased IL-8 mRNA signals were registered after stimulation with living and sonicated bacteria but not with filtrated supernatant. **Conclusions.** Preferential production of chemokines probably induced by membrane associate factors of C. jejuni acting on intestinal epithelial cells is presented. These chemokines are suggested to be part of an inflammatory network affecting cell types that contribute to initiation and/or resolution of the infection.

Boone, S. A. and C. P. Gerba "The occurrence of influenza A virus on household and day care center fomites." *Journal of Infection In Press, Corrected Proof*

<http://www.sciencedirect.com/science/article/B6WJT-4DPYJMT-2/2/1dd74cc83157ae5332b07fc981d46d29>

Objective The goal of this study was to evaluate the prevalence of influenza A virus on surfaces in day care and home settings to better assess the potential role of fomites in the transmission of influenza. **Methods** During two and a half years, 218 fomites were tested from 14 different day care centers. Ten different fomites from bathrooms, kitchens and play areas were sampled. In addition, 92 fomites from eight different homes with children were tested over 6 months. Fourteen different household fomites from bathrooms, kitchens and living areas were sampled. Influenza A viral RNA was detected using reverse transcriptase-polymerase chain reaction. **Results** Influenza was detected on 23% of day care fomites sampled during the fall and 53% of fomites sampled during the spring. Spring and fall sample data was determined to be statistically different at the 0.05 [alpha]-level by Chi-square analysis $PP=0.00002$. There was no statistical difference found between moist and dry fomites (Chi square $P=0.13998$). No influenza was detected on home fomites sampled during the summer. In contrast, influenza was detected on 59% of home fomites sampled during March. **Conclusions** Influenza A virus was detected on over 50% of the fomites

tested in homes and day care centers during influenza season.

Xu, J., J. E. Moore, et al. (2003). "Identification of a novel [alpha]-proteobacterium causing bacteraemia in an immunocompetent patient." Journal of Infection **47**(2): 167.

<http://www.sciencedirect.com/science/article/B6WJT-48S4KR9-1/2/a2e902ae243a0ac54f03fd8e41d71>

An 89-year male with pyrexia and suspected bacteremia was admitted to hospital, where a Gram-negative rod was identified from blood culture. The organism was difficult to identify phenotypically and the resulting sequencing of a 559 bp section of the 16S rRNA gene did not have a high homology score (>97.0%) with any deposited GenBank accession numbers and hence was not able to be assigned to a species within any genus. Given that the isolate was a member of the alpha subclass of the Proteobacteria but did not fall into any of the known genera with more than 93.7% homology (*Brucella*, *Rhizobium*, *Ochrobactrum*, *Agrobacterium*), we believe this isolate to represent a novel [alpha]-proteobacterium, which was the cause of bacteraemia in this patient.

Yee, E. K., L. J. Melkerson-Watson, et al. (2004). "Genomic analysis of penicillin-resistant *Streptococcus pneumoniae* in Southeastern Michigan." Journal of Infection **49**(2): 126.

<http://www.sciencedirect.com/science/article/B6WJT-4C604VR-1/2/0be762e87f0f3e339a3778882e328e39>

Objective. The emergence of multidrug resistance within *Streptococcus pneumoniae* population was analysed, correlating penicillin resistance Pen(R) with secondary antibiotic resistance, capsular serotype, and genetic diversity among isolates. **Methods.** DNA fingerprinting, following macro-restriction enzyme digestion and pulse field gel electrophoresis (PFGE), and restriction fragment analysis of the PBP 2b gene, following PCR amplification, were performed on the Pen(R) *S. pneumoniae*, among 377 clinical isolates obtained from the clinical microbiology laboratory (University of Michigan Medical Center). **Results.** Overall 35% of the isolates were Pen(R) of which 45% demonstrated high-level penicillin (Pen(R)-R, MIC>1). Respiratory isolates were more likely to be Pen(R). **Conclusion.** The emergence of multidrug resistance in the *S. pneumoniae* population in SE Michigan is not due to expansion of a single or limited number of resistant clones, is occurring most frequently in the paediatric population and is associated with a decreased susceptibility to penicillin.

Journal of Inorganic Biochemistry (2)

Colangelo, D., A. Ghiglia, et al. (2005). "Water-soluble benzoheterocycle trisium clusters as potential inhibitors of telomerase enzyme." Journal of Inorganic Biochemistry **99**(2): 505.

<http://www.sciencedirect.com/science/article/B6TGG-4DXTHPN-7/2/937bb71f23ed2a348438fe6da7121712>

We have studied the ability of several bioorganometallic clusters $[(\mu\text{-H})\text{Os}3(\text{CO})9(\text{L})([\mu\text{-}3\text{-}\eta^2\text{-}(\text{Q-H}))]$, where $\text{L} = [\text{P}(\text{C}_6\text{H}_4\text{SO}_3\text{Na})_3]$ or $[\text{P}(\text{OCH}_2\text{CH}_2\text{NMe}_3)_3]$, and $\text{Q} =$ quinoline, 3-aminoquinoline, quinoxaline or phenanthridine, of inhibiting telomerase, a crucial enzyme for cancer progression. In general, quinolines have shown interesting biological properties, especially in inhibiting enzymes. For example, the 2,3,7-trichloro-5-nitroquinoxaline (TNQX) exhibited strong anti-telomerase activity in vitro. Among the quinoline-clusters under study, only the negatively charged ones (by virtue of the sulfonated phosphines) exhibited good anti-telomeric activity on semi-purified enzyme in a cell-free assay, while they were ineffective in vitro on Taq, a different DNA-polymerase. On the contrary, the treatment of breast cancer MCF-7 cell line did not evidence any activity of these clusters, suggesting a low aptitude for crossing cell membrane. Furthermore, all clusters exhibited non-specific, acute cytotoxicity, probably due to accumulation on cell membranes by virtue of their amphiphilic character. A detailed study of Os uptake and accumulation in MCF-7 cells supported this hypothesis.

Kawakami, J., H. Imanaka, et al. (2000). "In vitro selection of aptamers that act with Zn^{2+} ." Journal of Inorganic Biochemistry **82**(1-4): 197.

<http://www.sciencedirect.com/science/article/B6TGG-41ST2C3-X/2/fd87e0f1cccc6bbc6c2ed2f74dbad108>

An in vitro selection was carried out with Zn^{2+} to isolate novel RNA molecules, zinc-dependent aptamers, that bind to HIV-1 Tat protein. RNAs bound to Tat were collected by using a nitrocellulose filter from a library of random RNAs and regenerated to the next generation of the RNA library by subsequent reverse transcription, polymerase chain reaction, and transcription. Sequences of the selected RNAs were determined after 6 and 12 rounds of the selection. The control clones after normal selection procedure with Mg^{2+} had a consensus UUG that resembled essential sequences of TAR or Arg aptamers. On the other hand, many unique sequences were revealed from a library selected with Zn^{2+} and the RNA with most abundant sequence (clone 31) bound to Tat tightly only when Zn^{2+} existed. The secondary structure of clone 31 RNA was predicted by using a computational prediction with our thermodynamic parameters and enzymatic scission of the RNA. Several model RNAs were prepared and the binding property of these RNAs to Tat were investigated. As a result, all the model RNAs did not reproduce the binding property of clone 31. Therefore, the Tat aptamer that acts with Zn^{2+} should require a relatively longer region of the sequence which is able to offer tertiary cooperation of several motifs for the binding.

Journal of Laboratory and Clinical Medicine (8)

Casonato, A., M. G. Cattini, et al. (2004). "A new L1446P mutation is responsible for impaired von Willebrand factor synthesis, structure, and function." Journal of Laboratory and Clinical Medicine **144**(5): 254.

<http://www.sciencedirect.com/science/article/B6WJW-4DW8K9J-D/2/6a41bcd30b2a10d3c6aed5a14feade47>

We report on a new mutation (4337T-->C) in exon 28 of the von Willebrand factor (VWF) gene, resulting in a substitution of L with P at residue 1446 (L1446P) of pre-pro-VWF. The defect is transmitted as a dominant trait and induces a reduced VWF synthesis, an abnormal VWF

multimer pattern and a deficient VWF-platelet glycoprotein Ib interaction. The proband had low plasma and platelet VWF antigen levels, a reduced VWF collagen-binding capacity, and a disproportionately low VWF ristocetin cofactor activity, associated with the absence of ristocetin-induced platelet aggregation. Multimer analysis showed that the smaller multimers were slightly low, whereas the larger ones were significantly reduced or absent, with a clear cutoff between the two patterns. Similar hemostatic findings were observed in the proband's sister and nephew. Desmopressin administration restored VWF levels to near normal, but this was not so for VWF ristocetin cofactor activity or ristocetin-induced platelet aggregation. VWF multimers improved after desmopressin, moreover, with the larger forms restored and the smaller ones still relatively more represented. Recombinant P1446 VWF synthesis was reduced at heterozygous level, and its multimer pattern was similar to that observed in plasma VWF. These findings confirm the role of L1446P mutation in determining the von Willebrand disease (VWD) phenotype observed in our patients. Given the lack of large and intermediate VWF multimers, and the fact that the VWF-platelet interaction defect appears to be partially independent of multimer pattern, the VWD associated with L1446P mutation may belong to the type 2A/2M VWD variant.

Chang, J.-M., M.-C. Kuo, et al. (2004). "1-[alpha],25-Dihydroxyvitamin D3 regulates inducible nitric oxide synthase messenger RNA expression and nitric oxide release in macrophage-like RAW 264.7 cells." Journal of Laboratory and Clinical Medicine **143**(1): 14.

<http://www.sciencedirect.com/science/article/B6WJW-4BHJ5WF-B/2/ce9dc20cfac369f9eb6ffce6024aea4c>

The expression of inducible nitric oxide synthase (iNOS) expression and release of nitric oxide (NO) from macrophages are markedly increased in granulomatous infections. Activation of macrophages 1[alpha]-hydroxylase results in an increase of 1[alpha],25-dihydroxyvitamin D3 [1,25(OH)2D3]. However, the significance of this increased production is not completely understood. In this study, we analyzed 1,25(OH)2D3 and NO production in patients with tuberculosis infection and hypercalcemia and used lipopolysaccharide (LPS) to stimulate RAW 264.7 cells in an attempt to assess iNOS expression and gaseous NO production regulated by 1,25(OH)2D3. Peroxynitrite (OONO-) production and lactate dehydrogenase activity were also examined. Without additional stimulation, peripheral-blood mononuclear cells (PBMCs) from patients with tuberculosis converted more 25-hydroxyvitamin D3 to 1,25(OH)2D3 than did those from normal controls. These PBMCs released less NO than did those from control subjects, at baseline and in the stimulated state. We found that 1,25(OH)2D3 dose-dependently inhibited iNOS messenger RNA expression of the LPS-stimulated RAW 264.7 cells and also significantly reduced the gaseous NO release and OONO- production. Paralleling the 1,25(OH)2D3-induced inhibition of NO release were reductions in OONO- and LDH production. In conclusion, 1,25(OH)2D3 inhibited iNOS expression and reduced NO production by LPS-stimulated macrophages in the range of physiological doses. Inhibition of the NO surge was coupled with a reduction in OONO- and LDH production. Increased 1,25(OH)2D3 production and decreased release of NO from the PBMCs of patients with tuberculosis and hypercalcemia were also noted. We propose that 1,25(OH)2D3 production by macrophages may protect themselves against oxidative injuries caused by the NO burst. In the case of tuberculosis infection, increased 1,25(OH)2D3 synthesis may further contribute to the development of an unwanted phenomenon--hypercalcemia.

Denomme, G. A., T. E. Warkentin, et al. (1997). "Activation of platelets by sera containing igg1 heparin-dependent antibodies: an explanation for the predominance of the Fc[gamma]rIIa "low responder" (his131) gene in patients with heparin-induced thrombocytopenia." Journal of Laboratory and Clinical Medicine **130**(3): 278.

<http://www.sciencedirect.com/science/article/B6WJW-4CT0YW9-12/2/b94a26f373b3bb0a31fb19f161dbd4e9>

Heparin-induced thrombocytopenia (HIT) is a prothrombotic disorder caused by heparin-dependent IgG (HIT-IgG) that recognizes a complex of heparin and platelet factor 4 (PF4), leading to platelet activation via the platelet Fc[gamma]IIa receptors (Fc[gamma]RIIa). Not all patients who generate HIT-IgG in response to heparin develop HIT, however, possibly because of observed differences in the ability of platelets from healthy individuals to be activated by HIT sera. It is known that a polymorphism in the platelet Fc[gamma]RIIa plays an important role in determining platelet reactivity to murine platelet-activating monoclonal antibodies of the IgG1 subclass: homozygous arg131 ("high responder" or HR) platelets respond well, and homozygous his131 ("low responder" or LR) platelets respond poorly, respectively, to these murine monoclonal antibodies. We sought to determine whether the differing risk for HIT among patients who receive heparin, as well as the variable platelet reactivity to HIT sera, could be explained by preferential activation by HIT-IgG of platelets bearing a particular Fc[gamma]RIIa phenotype. We found that the LR Fc[gamma]RIIa gene frequency was significantly overrepresented among 84 HIT patients, compared with that of 264 control subjects (0.565 versus 0.471; $p = 0.03$). We studied the subclass distribution of HIT-IgG against its major antigen, heparin/PF4 complexes, and found that 55 of 61 (90%) HIT sera expressed IgG1 antibodies either alone ($n = 47$) or in combination with IgG2 ($n = 5$) or IgG3 ($n = 3$). We then compared the platelet-activating profile of HIT sera with murine platelet-activating monoclonal antibodies. As expected, the murine IgG1 monoclonal antibodies preferentially activated platelets from homozygous HR individuals. In contrast, however, the LR homozygous platelets exhibited the greatest reactivity to HIT sera that contained predominantly anti-heparin/PF4 antibodies of the IgG1 subclass. We conclude that the significant overrepresentation of the LR (his131) gene among patients with HIT may be explained by the preferential activation of LR Fc[gamma]RIIa platelets by HIT antibodies of the IgG1 subclass, which is the predominant immunoglobulin subclass generated in HIT.

Giannini, C., F. Giannelli, et al. (1999). "Prevalence of mixed infection by different hepatitis C virus genotypes in patients with hepatitis C virus--related chronic liver disease." Journal of Laboratory and Clinical Medicine **134**(1): 68.

<http://www.sciencedirect.com/science/article/B6WJW-4CYXVS6-32/2/f0248820896baad3d457b0b2e9666162>

Multiple infection by different hepatitis C virus (HCV) genotypes may be of great clinico-pathologic interest. In this study we determined the effective prevalence of coinfections by two or more HCV genotypes in 213 subjects with HCV-positive chronic hepatitis by using genotype-specific polymerase chain reaction (PCR), genotype-specific probe hybridization, and direct sequencing. The most prevalent genotype was HCV-1b (54%). HCV-2 (a/c) was also prevalent (27%), and types 1a and 3a were found in 5% and 3% of patients, respectively. A mixed infection was detected in 23 patients (10.8%): 4 out of 23 were coinfecting by types 1a + 1b, while the remaining 19 patients had a 1b + 2 (a/c) mixed infection. Further analysis based on restriction fragment length polymorphism (RFLP) on type-specific PCR products was used to verify genotyping results. Only four coinfections (1a + 1b in 2 patients and 1b + 2 (a/c) in the remaining 2 patients, respectively) were confirmed by enzyme cleavage. All patients with true coinfection had long-lasting infection and liver cirrhosis. Both true and false mixed infections resulting from RFLP analysis were confirmed by direct sequencing of type-specific amplification products. We also determined a recurrent C/T transversion at position 618 in all sequenced samples. In 4 cases another point mutation (G/A at position 626) was found, reducing the number of mismatches between HCV-2 and HCV-1b from 4 to 3 (or 2). Interestingly, all HCV-2 isolates sequenced showed the highest degree of nucleotide homology with HCV-2 subtype c, confirming the relatively high prevalence of this subtype in Italy. In conclusion, we showed the possibility of multiple infection by different HCV types in the general population of chronically infected patients

without particular risk factors, even if in a low percentage of cases. Further studies are needed to assess the clinical relevance of chronic HCV infection with multiple genotypes.

Lipscomb, D., C. Bourne, et al. (1999). "DNA sequence of the canine platelet [beta]3 gene from cDNA: Comparison of canine and mouse [beta]3 to segments that encode alloantigenic sites and functional domains of [beta]3 in human beings." Journal of Laboratory and Clinical Medicine **134**(3): 313.

<http://www.sciencedirect.com/science/article/B6WJW-4CYXVWK-4C/2/f889685b677da7879eb34709a3a2a0b7>

The platelet glycoprotein complex [alpha]IIb[beta]3 is required for platelet-fibrinogen binding and platelet aggregation. This study was designed to characterize the nucleotide sequence of the canine platelet [beta]3 gene from cDNA. The nucleotide and deduced amino acid sequences of the canine [beta]3 gene were 92% and 96% homologous, respectively, with the sequences previously established for the [beta]3 gene of human beings. Within the [beta]3 gene, the nucleotide sequence of cDNA prepared from canine platelets shared homology of 89% for the cytoplasmic domain, 93% for the transmembrane domain, 92% for the extracellular domain, 94% for the arginine-glycine-aspartic acid (RGD) binding domain, and 97% for the region associated with Ca²⁺-dependent stabilization of the [alpha]IIb[beta]3 fibrinogen-binding pocket. The deduced amino acid sequence of canine [beta]3 was 100%, 97%, 96%, and 95% homologous with the cytoplasmic, transmembrane, extracellular, and RGD-binding domains, respectively, and was 100% homologous with the region associated with Ca²⁺-dependent stabilization of the [alpha]IIb[beta]3 fibrinogen-binding pocket of [beta]3 in human beings. The canine platelet cDNA signal peptide segment of the [beta]3 gene encodes for 22 amino acids, as compared with 26 amino acids previously reported for human beings. The deduced amino acid sequence of canine [beta]3 corresponds to the high-frequency allelic form for five of the six alloantigenic sites reportedly associated with human platelets: Leu33Leu40Pro407Arg489Arg636. The apparent amino acid residue in position 143 (Pen alloantigen) of canine platelet [beta]3 is histidine compared with arginine in human beings. Knowledge of the [beta]3 gene nucleotide sequence of normal dogs will facilitate the understanding of platelet [alpha]IIb[beta]3 structure-function relationships.

Mackenzie, R. K., N. Topley, et al. (1997). "Staphylococcal exoproducts down-regulate cyclooxygenase 1 and 2 in peritoneal macrophages." Journal of Laboratory and Clinical Medicine **129**(1): 23.

<http://www.sciencedirect.com/science/article/B6WJW-4CMYYM6-6B/2/aff53ced3b61ae386471386e629d4440>

Peritoneal macrophages (PMOs) are important components of the host defense against microbial infection in patients undergoing continuous ambulatory peritoneal dialysis (CAPD). Incubation of human PM[osol]s with cell-free supernatant (BFS), prepared from *Staphylococcus aureus*, inhibited prostaglandin E₂ (PGE₂) and thromboxane B₂ (TXB₂) production. Slot-blot analysis of cyclooxygenase-1 (Cox-1) and Cox-2 demonstrated a decrease in both Cox-1 (29%) and, to a greater extent, Cox-2 (65%) protein expression after BFS stimulation. When competitive polymerase chain reaction (PCR) was used, the peak levels of Cox-1 and Cox-2 messenger ribonucleic acid (mRNA) in unstimulated PMOs were 0.304 +/- 0.13 pmol/L and 9.61 +/- 2.84 pmol/L (mean +/- SEM, N = 3), respectively. After exposure of samples to BFS for 30 minutes, the level of Cox-2 mRNA was reduced to 0.59 +/- 0.449 pmol/L (16-fold reduction, p < 0.05). In contrast, these same PM[osol]s showed an increased expression of IL-6 mRNA and increased secretion of IL-6 protein. These results indicate that prostaglandin production in PM[osol]s is regulated by alterations in both immunoreactive Cox-1 and Cox-2. The down-regulation of Cox

metabolism in these cells is primarily related to the delayed and depressed increase in the Cox-2 gene product.

Takahashi, M., K. Tsuchiya, et al. (1997). "A role for Na/K adenosine triphosphatase in the pathogenesis of cyst formation in experimental polycystic kidney disease." Journal of Laboratory and Clinical Medicine **129**(5): 517.

<http://www.sciencedirect.com/science/article/B6WJW-4CN5N73-VI2/54bef7858315321dca6e69e8f1934558>

Multiple cyst formation with fluid retention is a characteristic structural abnormality in polycystic kidney disease (PKD). Na/K adenosine triphosphatase (ATPase) is a major transporting membrane protein that is ubiquitous in the epithelial cell, which has been thought to be involved in cystogenesis. We have investigated the molecular and histologic basis of Na/K ATPase activity in experimental PKD in vivo. Rats were treated with diphenylthiazole (100 mg/100 gm body weight), and cyst formation was examined histologically. Na/K ATPase activity was measured enzymatically by using a fluorometric method, and reverse transcription-competitive polymerase chain reaction (RT-PCR) analysis was used to quantitate mRNA levels in the isolated single nephron segment. Kidneys were immunostained with subunit-specific antibodies to determine the localization of Na/K ATPase in the epithelial cell. The enzyme activity increased in the cortical collecting duct from 25.9 $\pm$ 3.5 mmol/Lpmol/mm/min to 72.9 $\pm$ 6.8 pmol/mm/min and in the outer medullary collecting duct from 13.0 $\pm$ 3.9 mmol/Lpmol/mm/min to 58.5 $\pm$ 9.8 pmol/mm/min ($n = 6$, $p < 0.01$); however, all other segments showed no significant changes. No significant alternation in α 1- and β 1-subunits of Na/K ATPase mRNA levels was observed by competitive PCR assay in either segment. The enzyme was stained at the basolateral membrane even in the cystic tubules. Na/K ATPase activity was up-regulated in the cyst-formed kidney, but this was not accompanied with transcriptional up-regulation. Increased Na/K ATPase activity at normal locations may play a role in abnormal net fluid transport in the development and progression of experimental PKD.

Tang, D. C., S. Fucharoen, et al. (2001). "Rapid differentiation of five common α -thalassemia genotypes by polymerase chain reaction." Journal of Laboratory and Clinical Medicine **137**(4): 290.

<http://www.sciencedirect.com/science/article/B6WJW-45SJFPK-1J2/ea3abf80689aa421b51873c1c9140b92>

The α -thalassemias are common genetic disorders that arise from reduced synthesis of the α -globin chains. At present, large-scale carrier screening and clinically valuable antenatal detection programs have not been established for the congenital disorder α -thalassemia (α -thal). We have developed a simple nonradioactive polymerase chain reaction (PCR) approach that can detect and differentiate several common α -globin gene deletional α -thals regardless of the break points. When three primer sets were used—two gene-specific sets for the α 1- and α 2-globin genes and one set for the β -actin gene (serving as an internal control)—PCR products from genomic DNA were simultaneously amplified and analyzed after coamplification and gel electrophoresis. The number of α -globin genes present in the subjects was determined by the intensity of α 1 and α 2 bands normalized with that of β -actin when using densitometry. Our results demonstrate that five common genotypes of deletional α -thal are differentiated by the ratios of α 1/ β -actin and α 2/ β -actin. We also examined the feasibility of coupling this allele-specific amplification to a color-complementary assay. This easy and reproducible PCR assay is suitable for identifying α -thal carriers in screenings of large populations and improving genetic counseling. (J Lab Clin Med

Journal of Molecular and Cellular Cardiology (7)

Cremers, B., M. Flesch, et al. (2003). "Modulation of myocardial contractility by lysophosphatidic acid (LPA)." Journal of Molecular and Cellular Cardiology **35**(1): 71.

<http://www.sciencedirect.com/science/article/B6WK6-47S6CWX-2/2/17362036670bae78358631ef196759ac>

Lysophosphatidic acid (LPA) is a phospholipid messenger, which is released from activated platelets and leukocytes. This study examined the effects of LPA on myocardial contractility and characterized the signal transduction pathway involved in these effects. Functional effects of LPA were determined in isolated, electrically driven human myocardial preparations and rat cardiac myocytes. In human atrial and ventricular myocardial preparations, LPA (100 [μ]mol/l) decreased isoprenaline (0.03 [μ]mol/l) enhanced force of contraction by 17 $\pm$ 2% and 28 $\pm$ 3%, respectively. The effect of LPA was attenuated by suramin (1 mmol/l). In isolated rat cardiomyocytes, LPA (1-100 [μ]mol/l) concentration dependently abolished isoprenaline (0.03 [μ]mol/l) induced increase in cell shortening. This antiadrenergic effect was blunted after pretreatment with pertussis toxin (5 [μ]g/ml, 12 h). Forskolin (10 [μ]mol/l) stimulated adenylyl cyclase activity was inhibited by LPA in human myocardial membranes. PCR analysis of human atrial and ventricular cDNAs revealed the expression of two cognate LPA receptors: EDG-2 and EDG-7. Our results suggest that LPA exerts antiadrenergic effects on force of contraction in human and rodent myocardium via a G[α]i/o protein-mediated mechanism, most probably by LPA binding to the mammalian LPA receptors EDG-2 and/or EDG-7. This newly discovered action of LPA might be of pathophysiological importance in conditions like myocardial ischemia or inflammatory disorders when LPA release is enhanced.

Fodstad, H., H. Swan, et al. (2004). "Loss-of-function mutations of the K⁺ channel gene KCNJ2 constitute a rare cause of long QT syndrome." Journal of Molecular and Cellular Cardiology **37**(2): 593.

<http://www.sciencedirect.com/science/article/B6WK6-4CTCV39-3/2/3a379b3db65a7b788b42df5d0f1e0552>

Mutations of the KCNJ2 gene encoding the potassium channel Kir2.1 were previously shown to cause Andersen's syndrome (AS), a multisystem disease manifesting with developmental abnormalities, cardiac arrhythmias and periodic paralyses. We conducted a search for KCNJ2 mutations among 188 unrelated patients suspected to have long QT syndrome (LQTS). The screening was performed by denaturing high-performance liquid chromatography (dHPLC) and DNA sequencing. Two novel mutations of the KCNJ2 gene were detected: a missense threonine to alanine mutation (T75A) in the N-terminal region (family 1) and an in-frame deletion of two amino acids ([Δ]FQ163-164) in the M2 transmembrane region (family 2). In addition, a previously described silent polymorphism C1146T was detected. In family 1, some of the affected family members had a history of periodic muscle weakness characteristic of AS, but no dysmorphic features. The mean QTc interval of the affected members were 444 $\pm$ 24 ms (family 1, n=7) and 456 $\pm$ 8 ms (family 2, n=2). The mutations affect functionally important regions of the KCNJ2 channel protein: upon injection of the *Xenopus* oocytes with the wild type and mutant

KCNJ2 constructs, the channel proteins were correctly synthesized and localized to the cell surface, but no measurable inward K⁺ current could be detected for the mutant KCNJ2 constructs. In conclusion, we report two novel loss-of-function mutations of the KCNJ2 channel, affecting different domains of the channel protein. Mutations of the KCNJ2 gene should be considered in genetic subclassification of LQTS patients, even in the absence of overt manifestations of AS.

Gabel, S. A., V. R. Walker, et al. (2005). "Estrogen receptor beta mediates gender differences in ischemia/reperfusion injury." Journal of Molecular and Cellular Cardiology **38**(2): 289.

<http://www.sciencedirect.com/science/article/B6WK6-4F94YNH-4/2/77c721bb386528b4560ad87294814331>

Under hypercontractile conditions associated with increased intracellular calcium, male hearts show enhanced ischemia/reperfusion injury compared to female hearts. Our aim in this study was to identify the specific estrogen receptor involved in this gender difference. Following brief treatment with isoproterenol, isolated mouse hearts were subjected to ischemia and reperfusion. Postischemic contractile function and infarct size were measured in wild-type (WT) male and female hearts, and female hearts lacking functional alpha estrogen receptor ([alpha]ERKO), or the beta estrogen receptor ([ss]ERKO). WT male hearts exhibited significantly less functional recovery and more necrosis than WT females. [alpha]ERKO female hearts exhibited ischemia/reperfusion injury similar to that observed in WT females, whereas [ss]ERKO females exhibited significantly less functional recovery than WT females and were similar to WT males. These data suggest that estrogen, through the [ss]-estrogen receptor, plays a role in the protection observed in the female heart. Furthermore, we identified genes that were differentially expressed in [ss]ERKO female hearts compared to [alpha]ERKO and WT female hearts, and found altered expression of a number of metabolism genes, which may be important in ischemic injury. We further showed that WT female hearts have increased ratio of carbohydrate to fatty acid metabolism relative to WT males.

Gao, P. J., Y. Li, et al. (2003). "Differentiation of vascular myofibroblasts induced by transforming growth factor-[beta]1 requires the involvement of protein kinase C[alpha]." Journal of Molecular and Cellular Cardiology **35**(9): 1105.

<http://www.sciencedirect.com/science/article/B6WK6-493P6N1-2/2/7ada2bfeccc1fc2cfb4bb22007339cd9>

In response to vascular injury, adventitial fibroblasts can modulate their phenotype to myofibroblasts, cells that participate in arterial remodeling. However, the signaling mechanisms underlying the vascular myofibroblast differentiation remain unknown. Since protein kinase C (PKC) is a key enzyme for cell differentiation, we examined whether PKC isoforms were involved in the vascular myofibroblast differentiation. The association between PKC[alpha] and myofibroblast differentiation was investigated in cultured rat aortic fibroblasts treated with transforming growth factor-[beta]1 (TGF[beta]1). Confocal immunofluorescence microscopy indicated that fibroblasts expressed [alpha]-smooth muscle actin ([alpha]-SM actin) after TGF[beta]1 treatment. Moreover, TGF[beta]1 stimulation increased both PKC[alpha] mRNA expression (measured by real-time quantitative RT-PCR) and PKC activity (determined by histone-like pseudosubstrate phosphorylation) in adventitial fibroblasts. Western blot analysis indicated that PKC[alpha] protein expression was higher in TGF[beta]1-treated fibroblasts than in untreated cells. TGF[beta]1-induced expression of [alpha]-SM actin was inhibited in a dose-dependent manner by treating cells with a PKC inhibitor, calphostin C, and was abolished by depleting PKC[alpha] with antisense PKC[alpha] oligodeoxynucleotides. Our results demonstrate

that TGF[β]1 induces adventitial myofibroblast differentiation via a PKC[α]-dependent process.

Nakajima-Taniguchi, C., H. Matsui, et al. (1995). "Novel missense mutation in [alpha]-tropomyosin gene found in Japanese patients with hypertrophic cardiomyopathy." Journal of Molecular and Cellular Cardiology **27**(9): 2053.

<http://www.sciencedirect.com/science/article/B6WK6-4BSF46K-X/2/8770d569c5d38aad5bc2295ca89b99c5>

We have searched for mutations in [alpha]-tropomyosin gene in 50 Japanese patients with hypertrophic cardiomyopathy (HCM) by means of polymerase chain reaction (PCR)-single strand conformation polymorphism (SSCP) analysis. Two missense mutations of the [alpha]-tropomyosin gene were detected in Japanese patients with familial HCM. Sequencing analysis revealed a C to T transition at codon 63 leading to a replacement of Ala with Val residue, and a G to A transition with replacement of Asp by Asn at codon 175. These missense mutations were found at residues which were markedly conserved across the species, and have been reported to interact with troponin T. This is the first report on a mutant [alpha]-tropomyosin gene in a Japanese Population. Familial HCM is a genetically heterogeneous disease in Japanese patients, similar to that reported in Caucasian kindreds.

Tang, Z., B. S. McGowan, et al. (2004). "Gene expression profiling during the transition to failure in TNF-[alpha] over-expressing mice demonstrates the development of autoimmune myocarditis." Journal of Molecular and Cellular Cardiology **36**(4): 515.

<http://www.sciencedirect.com/science/article/B6WK6-4BYRS5M-1/2/defba54e050b9e64e7204dcd6b22e11d>

Transgenic mice with cardiac-specific over-expression of tumor necrosis factor-[alpha] (TNF1.6) progress to dilated heart failure. A significant inflammatory response precedes functional deterioration, and may contribute to cardiac damage in this model. To evaluate the underlying molecular mechanisms, we assessed the gene expression in six groups of mouse hearts defined by age, gender, and phenotype (n = 3/group) using Affymetrix microarray analysis. Phenotype was defined as compensated (in young TNF1.6) or decompensated (in older TNF1.6) via echocardiogram. Of the >1000 transcripts altered in the compensated hearts (fold change > 2, P < 0.05), 50 genes were differentially regulated, including seven immunoglobulin genes. Real-time reverse transcriptase-polymerase chain reaction and cDNA microarray confirmed the Affymetrix data. Mac3⁺ macrophages, CD4⁺ T and CD45/B220⁺ B-cells were identified in both compensated and decompensated hearts. However, a large amount of IgG was found deposited in areas devoid of B-lymphocytes in the myocardium of decompensated TNF1.6 mice; no such accumulation was seen in the compensated or age-matched controls. Furthermore, nuclei density analyses showed a two-fold increase in the myocardium of both compensated and decompensated TNF1.6 mice (vs. WT). This study suggests that TNF-[alpha] over-expression activates not only the inflammatory response, but also humoral immune responses within the transgenic hearts. The autoimmune response occurs concomitantly with cardiac decompensation and may participate in triggering the transition to failure in TNF1.6 mice.

Yu, C.-M., K. Wing-Hon Lai, et al. (2004). "Normalization of renal aquaporin-2 water channel expression by foscarnil, valsartan, and combination therapy in congestive heart failure: a new mechanism of

action." Journal of Molecular and Cellular Cardiology **36**(3): 445.

<http://www.sciencedirect.com/science/article/B6WK6-4BJ0TXN-1/2/5ee3172d3cee0ac68ce3d81d3818b38a>

This study investigated the effect of fasinopril (Fos), valsartan (Val), and combination of both drugs (Fos + Val) on the cardiac and renal expression of aquaporin-1 (AQP1) and aquaporin-2 (AQP2) in congestive heart failure (CHF). A rat model of CHF was created by ligating the left anterior descending coronary artery to induce acute myocardial infarction (AMI). Rats were treated by Fos, Val, or Fos + Val for 4 weeks. In renal medulla and cortex, AMI was associated with 2.2- and 1.8-fold increase in AQP2 mRNA expression when compared with Sham-operated rats (medulla: 23.6 $\pm$ 2.8 vs. 52.3 $\pm$ 8.7%; P P P = NS vs. Sham) and in the cortex (Fos, 21.2 $\pm$ 6.7%; Val, 20.4 $\pm$ 6.0%; Fos + Val, 18.9 $\pm$ 7.5%; P = NS vs. Sham). Similarly, the AQP2 protein expression increased by 2.1-fold after CHF (P P P < 0.05). The renal and cardiac AQP1 gene and protein expressions were unaltered in CHF or by medical therapy. There was no observed cardiac AQP2 expression in all the study groups. Treatment with Fos, Val, or combination therapy was effective in preventing the upregulation of renal AQP2 gene and protein expressions in CHF rats caused by AMI.

Journal of Neuroimmunology (78)

Bauer, J., U. Ganter, et al. (1993). "Effects of interleukin-1 and interleukin-6 on metallothionein and amyloid precursor protein expression in human neuroblastoma cells: Evidence that interleukin-6 possibly acts via a receptor different from the 80-kDa interleukin-6 receptor." Journal of Neuroimmunology **45**(1-2): 163.

<http://www.sciencedirect.com/science/article/B6T03-476WCFH-WM/2/9f385781b125e3e5aeebd6441f7ef5bf>

Since immunohistochemical studies indicated the presence of interleukin-6 in the cortices of patients with Alzheimer's disease, we were interested in the eventual biological effects of this cytokine on neuronal cells. We found that interleukin-6 and interleukin-1 induced metallothionein expression in a human neuronal (SH-SY5Y neuroblastoma) cell line. In contrast to metallothionein, amyloid precursor protein expression was unaffected by both cytokines. When searching in the same cell line for the expression of the classical 80-kDa interleukin-6 binding protein, which is part of the dimeric interleukin-6 receptor, we were unable to detect the respective mRNA. Our findings either indicate that the interleukin-6 receptor in these cells is expressed in extremely low levels or that interleukin-6 may act upon neuronal cells via a different, yet unknown neuronal receptor.

Bencsik, A., C. Malcus, et al. (1996). "Selective induction of cytokines in mouse brain infected with canine distemper virus: structural, cellular and temporal expression." Journal of Neuroimmunology **65**(1): 1.

<http://www.sciencedirect.com/science/article/B6T03-3VXN38M-1/2/58491b94d58ac7369728972e5406dad0>

We have previously shown that, in experimentally inoculated mice, canine distemper virus (CDV), a neurotropic virus, selectively infects certain brain structures (hypothalamus, hippocampus, monoaminergic nuclei, etc). Here we demonstrate that tumor necrosis factor (TNF)-[alpha], interleukin (IL)-1 [beta] and IL-6 transcripts are selectively expressed in these CDV-targeted structures, except in the dentate gyrus, where cytokines are induced without prior CDV replication. The time-course of TNF-[alpha] expression vs. viral replication in the hypothalamus was different from that in hippocampus. In addition, we show that a substantial number of neurons express TNF-[alpha] and IL-6. These findings provide new insights into the possible participation of cytokines in the neurological disorders triggered by CDV infection.

Blanco-Jerez, C., J. F. Plaza, et al. (2002). "Increased levels of IL-15 mRNA in relapsing-remitting multiple sclerosis attacks." Journal of Neuroimmunology **128**(1-2): 90.

<http://www.sciencedirect.com/science/article/B6T03-45Y6MNW-1/2/09a8a6a5fc44d41e36826545f77b7584>

IL-15 is a proinflammatory cytokine which has recently been implicated in multiple sclerosis (MS) pathogenesis, where it may play a role in the initiation and/or progression of the disease. We have used reverse transcriptase-polymerase chain reaction (RT-PCR) to study IL-15 mRNA levels in peripheral blood mononuclear cells (PBMC) from healthy controls and relapsing-remitting MS (RRMS) patients in a stable phase of the disease and during a bout, both before and after corticosteroid treatment (CST). IL-15 mRNA expression was found to be similar in controls and stable patients. We have detected an increased level of IL-15 mRNA in PBMC of patients with a relapse, which was maintained after CST. We have also found an inverse correlation between PBMC IL-15 mRNA levels at the onset of the relapse and the time elapsed since the previous attack, as well as an absence of correlation between IL-15 mRNA levels and the patient demographic and clinical characteristics. Results in the present work further suggest a role for IL-15 in MS pathophysiology.

Braun, A., P. Wiebe, et al. (1999). "Differential modulation of human immunoglobulin isotype production by the neuropeptides substance P, NKA and NKB." Journal of Neuroimmunology **97**(1-2): 43.

<http://www.sciencedirect.com/science/article/B6T03-3WS61MX-7/2/10ed0fa9c335c765b28aef507c095727>

The modifying effects of tachykinins substance P, neurokinin A and neurokinin B on immunoglobulin production were analyzed in an in vitro culture system. Purified human T- and B-cells were stimulated with TGF[beta]2 and IL-5 to induce preferential IgA production. Neuropeptides had the following effects. (1) The levels of IgA and IgG4 production were enhanced by IL-5 and TGF[beta]2; IgA levels remained constant or were slightly augmented by neuropeptides, whereas IgG4 was further augmented. (2) IL-5 and TGF[beta]2 did not alter IgG3 production, but neuropeptides stimulated secretion of this subclass. (3) IgG1 and IgM production were inhibited by IL-5 and TGF[beta]2. This effect was prevented by neuropeptides. (4) Other isotypes including IgG2 and IgE remained unaffected. Except for IgM, these effects were blocked by specific receptor antagonists indicating specificity. The tachykinin receptor NK-1 mRNA was detected in B- and T-cells, whereas NK-3 mRNA was only present in T- and B-cell coculture following activation. Furthermore, neuropeptide effects depended on cytokine co-stimulation and the presence of T-cells. These results suggest that neuropeptides are potent modifiers of preferential IgA synthesis.

Breijl, E. C. W., W. L. van der Pol, et al. (2003). "No association of Fc[gamma]RIIa, Fc[gamma]RIIIa and Fc[gamma]RIIIb polymorphisms with MS." Journal of Neuroimmunology **140**(1-2): 210.

<http://www.sciencedirect.com/science/article/B6T03-491GS5M-8/2/eafc30d47bdc4254bfdc5c5b86ba2cf7>

Anti-myelin IgGs occur in the cerebrospinal fluid (CSF) and serum of multiple sclerosis (MS) patients, and can induce inflammatory effector functions in leukocytes by crosslinking IgG receptors (Fc[gamma]R). The efficiency of Fc[gamma]R-mediated inflammatory processes is affected by functional polymorphisms of three Fc[gamma] receptors (Fc[gamma]RIIa, Fc[gamma]RIIIa, Fc[gamma]RIIIb). The relevance of Fc[gamma]R polymorphisms in MS was evaluated by studying the distribution of Fc[gamma]RIIa, Fc[gamma]RIIIa and Fc[gamma]RIIIb genotypes in 432 MS patients and 515 healthy controls. No significant differences were found between MS patients and controls, or between subgroups of patients. We conclude that Fc[gamma] receptor polymorphisms influence neither susceptibility nor clinical disease course of MS.

Carlson, K. A., J. Limoges, et al. (2004). "OTK18 expression in brain mononuclear phagocytes parallels the severity of HIV-1 encephalitis." Journal of Neuroimmunology **150**(1-2): 186.

<http://www.sciencedirect.com/science/article/B6T03-4C09KS6-1/2/79a3e718c365989b2d693ad4b037a167>

OTK18 was isolated by mRNA differential display of human monocyte-derived macrophages (MDM) infected with human immunodeficiency virus type one (HIV-1). Northern blot and real-time reverse transcription polymerase chain reaction showed low levels of OTK18 expression in human tissue, which markedly increased during advanced HIV-1 encephalitis (HIVE). Immunocytochemistry, using rabbit polyclonal antisera, showed OTK18 localized to brain mononuclear phagocytes (MP) in moderate to severe HIV-1 encephalitis. OTK18 expression was selective and not found in HIV-1-infected brain tissue with limited neuropathological abnormalities, nor in cytomegalovirus encephalitis, multiple sclerosis, Alzheimer's disease, or uninfected control brains. Thus, OTK18 expression in brain mononuclear phagocytes is a signature for advanced HIV-1 encephalitis.

Charles, P. C., K. S. Weber, et al. (1999). "Cytokine, chemokine and chemokine receptor mRNA expression in different strains of normal mice: implications for establishment of a Th1/Th2 bias." Journal of Neuroimmunology **100**(1-2): 64.

<http://www.sciencedirect.com/science/article/B6T03-3YC05J7-9/2/6dda8cfd3b491dfc1490c8ab514194e9>

The resistance or susceptibility of inbred strains of mice to various pathogens and autoimmune diseases such as EAE has been linked to differences in the balance between cytokines associated with Th1- and Th2-type immune responses. Previous work from this laboratory on the mouse strain specific resistance to mouse adenovirus type I (MAV-1)-induced encephalopathy revealed subtle differences in the transcription rates of several immunologically important molecules that was evident prior to infection. In this study, we show striking differences in cytokine, chemokine and chemokine receptor mRNA expression in the spleens of normal, immunologically naive C57BL/6J, BALB/cJ and SJL/J mice. Messenger RNAs for interferon (IFN)-[gamma] and the chemokine IFN [gamma] inducible protein (IP)-10 were preferentially expressed in C57BL/6J spleens, whereas in BALB/cJ spleens mRNAs for lymphotoxin-[beta], interferon-

[beta], transforming growth factor-[beta], and the chemokine receptors CCR3 and CXCR4 predominated. A unique profile of chemokine receptors was found in spleens from normal SJL/J mice that correlated with the presence of polymorphisms within the CCR-3 gene. The patterns of gene expression fit well into the Th1/Th2 paradigm for C57BL/6J and BALB/cJ strains and suggest an important role for chemokines, as well as cytokines, in contributing to the genetic basis of the immune response.

Chataway, J., S. Sawcer, et al. (1999). "A screen of candidates from peaks of linkage: evidence for the involvement of myeloperoxidase in multiple sclerosis." Journal of Neuroimmunology **98**(2): 208.

<http://www.sciencedirect.com/science/article/B6T03-3WXNYG7-H/2/a11f7977dd34eebeb084cd06f0ba4f00>

We tested 11 microsatellite markers for evidence of transmission distortion in 744 trio families with multiple sclerosis. Ten of the markers lie within or near to candidate genes selected on the basis that they map within the regions of potential linkage identified in our previously reported linkage genome screen, while the eleventh is an anonymous marker which had previously shown modest evidence for transmission distortion in our sibling pair families. Only the marker related to the myeloperoxidase (MPO) gene revealed tentative evidence for linkage disequilibrium and further work on this gene is clearly needed in order to resolve the status of this region in conferring susceptibility to multiple sclerosis.

Chataway, J., S. Sawcer, et al. (1999). "No evidence for association of multiple sclerosis with the complement factors C6 and C7." Journal of Neuroimmunology **99**(1): 150.

<http://www.sciencedirect.com/science/article/B6T03-3Y9H4FG-M/2/006eb49aaead687e5912560850d8ed38>

Four genome screens in multiple sclerosis have been completed and each has identified evidence for linkage in the pericentromeric region of chromosome 5. This region encodes a number of candidate genes including those for the complement components C6, C7 and C9. We have used a multiplexed oligoligation assay (OLA) to test single nucleotide polymorphisms (SNPs) from the C6 and C7 genes for evidence of association with multiple sclerosis in our sibling pair families. There was no statistically significant difference in the allele frequencies of these polymorphisms in the index cases from our families when compared with locally derived controls. No evidence for transmission distortion was seen with any of the polymorphisms, or with the haplotype built from the three SNPs from the C7 gene. Despite offering themselves as potential candidates these complement genes appear not to confer susceptibility to multiple sclerosis.

Cross, A. H., R. M. Keeling, et al. (1996). "Inducible nitric oxide synthase gene expression and enzyme activity correlate with disease activity in murine experimental autoimmune encephalomyelitis." Journal of Neuroimmunology **71**(1-2): 145.

<http://www.sciencedirect.com/science/article/B6T03-3R867H0-N/2/398eccff619d17193412e3b089c7f4d>

Messenger RNA encoding inducible NO synthase (iNOS) was measured by competitive reverse transcriptase polymerase chain reaction (cRT-PCR) and ribonuclease protection assays in spinal cords from mice at varying stages of experimental allergic encephalomyelitis (EAE) and from

control mice. iNOS mRNA was increased in spinal cords from mice with acute EAE. cRT-PCR assays revealed a 10-20-fold increase in iNOS mRNA in spinal cords during acute EAE compared with the level observed in normal mouse spinal cords. Functional iNOS activity, as assessed by assay of calcium-independent citrulline production, was also significantly increased in spinal cords from mice with acute EAE in comparison to normal controls. The correlation of functional iNOS expression with active disease in EAE is consistent with a pathogenic role for excess NO in this model of cell-mediated central nervous system autoimmunity.

DeVry, C. G., M. Valdez, et al. (2004). "RDP58, a novel immunomodulatory peptide, ameliorates clinical signs of disease in the Lewis rat model of acute experimental autoimmune encephalomyelitis." Journal of Neuroimmunology **152**(1-2): 33.

<http://www.sciencedirect.com/science/article/B6T03-4CPP63V-4/2/48b93709658bd511b2083b1e6b810abe>

The therapeutic value of a novel immunomodulatory peptide, RDP58, was investigated in the acute experimental autoimmune encephalomyelitis (EAE) model of Multiple Sclerosis (MS). RDP58 is a 10-amino acid peptide with two major activities: (i) inhibition of inflammatory TH1 cytokines such as TNF[alpha], IFN[gamma], and IL12 and (ii) up-regulation of heme oxygenase-1 (HO-1) expression. Experiments in which EAE-induced Lewis rats exhibit an acute monophasic episode of disease demonstrated that a single intracerebroventricular injection of RDP58 is effective in preventing clinical signs of disease. The therapeutic effect on disease activity was observed at all pre-onset administration times and at all doses tested. Consistent with disease activity in vivo, RDP58-treated animals had reduced cellular infiltration within the spinal cord along with decreased TNF[alpha] expression levels. The data in this proof of concept study support the premise that RDP58, as a platform molecule, may be a promising new therapeutic intervention in autoimmune and inflammatory diseases.

Elovaara, I., U. Utz, et al. (1995). "Limited T cell receptor usage by HTLV-I tax-specific, HLA class I restricted cytotoxic T lymphocytes from patients with HTLV-I associated neurological disease." Journal of Neuroimmunology **63**(1): 47.

<http://www.sciencedirect.com/science/article/B6T03-4002J2F-M/2/26443ea37a654ce0141374195444a3b5>

T cell receptor (TCR) V[alpha] and V[beta] chain usage of HTLV-I tax-specific, HLA class I restricted CD8+ cytotoxic T cells (CTL) was determined from lymphocytes obtained from peripheral blood of patients with HTLV-I associated neurological disease. To characterize TCR repertoire, CD8+ lymphocytes from peripheral blood were cloned in limiting dilution, and the resulting wells were screened for HTLV-I-specific precursor CTL activity. RNA was isolated from HLA-A2 restricted HTLV-I tax peptide-specific (tax 11-19; LLFGYPVYV) CD8+ CTL lines and cDNA was analyzed by PCR amplification using V[alpha] and V[beta] chain family-specific oligonucleotide primers. The results indicate that CD8+ cytotoxic T cell lines from HLA-A2 HAM/TSP patients express a limited repertoire of T cell receptor chains which may correlate with duration and severity of disease. The restricted use of TCR genes expressed by antigen-specific CTL may play a critical role in the pathogenesis of HAM/TSP and may be of value in developing immunotherapeutic strategies that focus on eliminating these cells or inhibiting their activity.

Floris, S., S. R. Ruuls, et al. (2002). "Interferon-[beta] directly influences monocyte infiltration into the

central nervous system." Journal of Neuroimmunology **127**(1-2): 69.

<http://www.sciencedirect.com/science/article/B6T03-45NGR1M-1/2/4f80169144df9e63ab2767cdcf88c273>

Interferon-[beta] (IFN-[beta]) has beneficial effects on the clinical symptoms of multiple sclerosis (MS) patients, but its exact mechanism of action is yet unknown. We here suggest that IFN-[beta] directly modulates inflammatory events at the level of cerebral endothelium. IFN-[beta] treatment resulted in a marked reduction of perivascular infiltrates in acute experimental allergic encephalomyelitis (EAE), the rat model for MS, which was coupled to a major decrease in the expression of the adhesion molecules ICAM-1 and VCAM-1 on brain capillaries. In vitro, IFN-[beta] reduced the mRNA levels and protein expression of adhesion molecules of brain endothelial cell cultures and diminished monocyte transendothelial migration. Monocyte adhesion and subsequent migration was found to be predominantly regulated by VCAM-1. These data indicate that IFN-[beta] exerts direct antiinflammatory effects on brain endothelial cells thereby contributing to reduced lesion formation as observed in MS patients.

Fujii, T., N. Ushiyama, et al. (2002). "Effects of human antithymocyte globulin on acetylcholine synthesis, its release and choline acetyltransferase transcription in a human leukemic T-cell line." Journal of Neuroimmunology **128**(1-2): 1.

<http://www.sciencedirect.com/science/article/B6T03-45V716F-1/2/e7bf261425e7842c25a4ec782ac473ce>

Lymphocytes possess an independent, nonneuronal cholinergic system. In the present study, we investigated the short- and long-term effects of antithymocyte globulin (ATG)-Fresenius (ATG-F), a human antithymocyte globulin that binds to CD2, CD7 and CD11a, on acetylcholine (ACh) synthesis and transcription of choline acetyltransferase (ChAT) in CCRF-CEM cells, a human leukemic T-cell line. In the short-term (6 h), ATG-F enhanced ACh release, likely through transient increases in intracellular Ca^{2+} ($[Ca^{2+}]_i$) mediated by CD7, which led to declines in intracellular ACh content. By 48 h, however, the ACh content had increased as compared to control due to up-regulation of ChAT expression mediated by CD11a.

Fujii, T., S. Yamada, et al. (1998). "Induction of choline acetyltransferase mRNA in human mononuclear leukocytes stimulated by phytohemagglutinin, a T-cell activator." Journal of Neuroimmunology **82**(1): 101.

<http://www.sciencedirect.com/science/article/B6T03-3SR9W9C-G/2/5fb9e082b826e109d86bc5dd93d250a8>

The induction of mRNA for choline acetyltransferase (ChAT), which catalyzes acetylcholine (ACh) synthesis was investigated in human mononuclear leukocytes (MNL) stimulated by phytohemagglutinin (PHA), a T-cell activator, using the reverse transcription-polymerase chain reaction. Stimulation of MNL by PHA induced the expression of ChAT mRNA, and potentiated ACh synthesis. ChAT mRNA induction required more time than the induction of interleukin-2 mRNA. Expression of the gene encoding the vesicular ACh transporter, which mediates ACh transport in cholinergic neurons, was not observed in PHA-stimulated MNL, suggesting that the mechanisms controlling ACh release from T-lymphocytes differ from those in cholinergic neurons. These findings demonstrate that activation of T-lymphocytes up-regulates ACh synthesis in the blood, and suggest that ACh plays an important role as a neuroimmunomodulator besides its role as a neurotransmitter.

Fyhr, I.-M., A.-R. Moslemi, et al. (1998). "T cell receptor [beta]-chain repertoire in inclusion body myositis." Journal of Neuroimmunology **91**(1-2): 129.

<http://www.sciencedirect.com/science/article/B6T03-3V5VDX7-K/2/5022ebb62f3b601e7ec172e1bb382457>

Inclusion body myositis (IBM) is the most common muscle disease affecting individuals over 50 years of age. The inflammatory reaction is characterized by cell infiltrates predominated by CD8+ cytotoxic T cells. To analyze clonality of muscle infiltrating lymphocytes, we studied the complementarity determining region 3 (CDR3) length distribution of the T cell receptor (TCR). Muscle infiltrating lymphocytes were studied in three IBM patients and compared with peripheral blood lymphocytes (PBL) in two of these patients. The study was performed by reverse transcription polymerase chain reaction (RT-PCR) of RNA extracted from muscle tissue and PBL followed by analysis of fragment length distribution of the CDR3 region in each of 24 different V[beta] families. There was a restricted usage of TCR V[beta] gene families in muscle infiltrating T cells in all three patients. Some of the TCR V[beta] gene families showed oligoclonal expansions but polyclonal patterns were dominating. The CDR3 distribution of most V[beta] families differed between muscle infiltrating lymphocytes and PBL indicating that T cells have expanded locally or selectively accumulated in muscle.

Goldmuntz, E. A., R. L. Wilder, et al. (1993). "The origin of the autoimmune disease-resistant LER rat: An outcross between the Buffalo and autoimmune disease-prone Lewis inbred rat strains." Journal of Neuroimmunology **44**(2): 215.

<http://www.sciencedirect.com/science/article/B6T03-476W9PJ-7C/2/e5c0f182c0482ff214cd8266eeedd8d5>

The Lewis (LEW) rat strain is highly susceptible to a large number of experimentally induced inflammatory and autoimmune diseases. The Lewis resistant (LER) rat strain, which reportedly arose as a spontaneous mutation in a closed colony of LEW rats, is resistant to many of these disorders. The mechanism of resistance is not yet clear. We report the analysis of 19 simple dinucleotide repeat polymorphisms in 13 rat strains including the LEW/N and LER/N rat strains. The LEW/N and LER/N alleles were the same in only 42% of cases. For all of the other polymorphisms, the LER/N and Buffalo (BUF/N) rat strain alleles were identical. These data provide evidence that the LER strain did not arise as a spontaneous mutation in the LEW strain but is the result of an outcross between the LEW and BUF rat strains. The LER rat strain is now a recombinant inbred rat strain. This information should facilitate the genetic analysis of the loci responsible for resistance to experimental autoimmune disease in the LER rat.

Guo, C.-J., J.-P. Lai, et al. (2002). "Substance P up-regulates macrophage inflammatory protein-1[beta] expression in human T lymphocytes." Journal of Neuroimmunology **131**(1-2): 160.

<http://www.sciencedirect.com/science/article/B6T03-46WV6NX-6/2/4406c82190b5431c55606624ffa4d78b>

Substance P (SP) is an important modulator of neuroimmunoregulation. We have demonstrated that human T lymphocytes express SP and neurokinin-1 receptor (NK-1R), a primary SP receptor. In the present study, we investigated whether SP stimulates synthesis of macrophage inflammatory protein-1[beta] (MIP-1[beta]) in human T lymphocytes. SP significantly enhanced

MIP-1[beta] expression at both the mRNA and protein level in a human T cell line (Jurkat) containing the SP receptor gene (J-SPR) as determined by real-time PCR and ELISA assays. SP-induced MIP-1[beta] expression is abrogated by the specific NK-1R antagonist (CP-96,345). The supernatants from SP-stimulated J-SPR T cell cultures enhanced T lymphocyte chemotaxis in vitro, indicating functional activity of SP-induced MIP-1[beta]. In addition, SP augmented secretion of MIP-1[beta] from primary cultures of peripheral blood lymphocytes (PBL) isolated from some of the donors. This donor variability was due to differential expression of the primary SP receptor (NK-1R) on PBL from different donors. PBL from two of seven donors that did not respond to SP stimulation had undetectable NK-1R expression. Our mechanistic studies showed that SP activated NF-[kappa]B promoter-directed luciferase activity, which may be responsible for its effect on MIP-1[beta] expression in human T cells. Our data provide a potential mechanism by which SP selectively influences cellular immune responses such as [beta]-chemokine expression in human T lymphocytes through NK-1R, which may have an important in vivo implication in inflammatory diseases.

Hackstein, H., A. Bitsch, et al. (2001). "Analysis of interleukin-4 receptor [alpha] chain variants in multiple sclerosis." *Journal of Neuroimmunology* **113**(2): 240.

<http://www.sciencedirect.com/science/article/B6T03-427JWJW-9/2/128f9e707281c5647e0ffc1b474a8027>

A recent candidate gene study employing microsatellite markers suggested a possible linkage of multiple sclerosis (MS) with the interleukin-4 receptor (IL4R) gene. Consequently, we investigated the association of different IL4R variants with MS in 341 german MS patients and 305 healthy controls. Analysis of the first 100 MS patients for six IL4R variants showed an increased frequency of the R551 variant in MS patients versus healthy controls and carriage of the same IL4R variant was weakly associated with myelin oligodendrocyte glycoprotein (MOG) autoantibody production. However, further analysis of all 341 MS patients did not confirm the finding that this IL4R variant represents a general genetic risk factor for MS but revealed an increased frequency of the R551 variant in MS patients with primary progressive MS (PPMS, n=48) as compared to patients with relapsing remitting MS or secondary progressive MS (RR/SPMS n=284; P=0.005 for genotype differences) and to 305 healthy controls (P=0.001 for genotype differences). This association was statistically independent of the presence of the well-known MS susceptibility allele HLA-DRB1*15. After correction for multiple comparisons only the genotype differences between PPMS patients and healthy controls remained statistically significant. These results indicate, that the IL4R variant R551 may influence the genetic predisposition for PPMS but does not represent a general genetic risk factor for MS.

Hardin-Pouzet, H., P. Giraudon, et al. (1996). "Cytokines are increased in the rat hippocampus after serotonergic neuron degeneration and upregulate the expression of GDH, an enzyme involved in glutamate detoxification." *Journal of Neuroimmunology* **69**(1-2): 117.

<http://www.sciencedirect.com/science/article/B6T03-49GTP2H-19/2/6932d464541a8f40161aff277bcc5a8a>

The degeneration of serotonergic neurons increases the expression of glutamate dehydrogenase (GDH) in hippocampal astrocytes. This process was demonstrated to be independent of the serotonin level. At the same time, upregulation of tumor necrosis factor (TNF) α and interleukin (IL)-1[alpha] mRNA were observed, whereas levels of transforming growth factor (TGF) [beta]1 mRNA remained unchanged. The level of GDH mRNA was increased in primary cultures of hippocampal astrocytes treated with TNF[alpha] and IL-1[alpha] suggesting that these cytokines act on the GDH metabolism. TNF α and IL-1[alpha] induced an increase in GDH promoter activity

in C8S (an astrocytic cell line) transfected with constructs containing 5' flanking genomic sequences of GDH driving the expression of a reporter gene. These observations suggest that cytokines may be signals that upregulate the astrocytic GDH expression in response to the degeneration of serotonergic terminals in the hippocampus.

He, B., V. Navikas, et al. (1995). "Tumor necrosis factor [alpha]-308 alleles in multiple sclerosis and optic neuritis." Journal of Neuroimmunology **63**(2): 143.

<http://www.sciencedirect.com/science/article/B6T03-4002J1P-5/2/2c722b17a858484652efeaefdf753399>

Tumor necrosis factor-[alpha] (TNF-[alpha]), a proinflammatory cytokine, is believed to play an important role in multiple sclerosis (MS) pathogenesis. A bi-allelic polymorphism in the TNF-[alpha] promoter region (TNF[alpha]-308), has been reported to influence levels of TNF-[alpha] production. In the present study, we investigated the TNF[alpha]-308 polymorphism in 93 patients with MS, 17 patients with optic neuritis (ON) and 95 healthy individuals using an allele-specific PCR technique. Allelic genotype was compared with TNF-[alpha] mRNA expression levels and HLA class II phenotypes. No significant difference regarding the TNF[alpha]-308 polymorphism was observed between MS patients and controls. Specifically, the less common allele, TNF2, which is associated with higher expression levels of TNF-[alpha], was somewhat less frequent among MS patients. In fact, analysis of 19 patients homozygous for the MS associated HLA-DR-DQ haplotype HLA-Dw2 showed that this haplotype does not carry the TNF2 allele. In addition, in 47 patients, the TNF-[alpha] alleles did not correlate with expression levels measured as numbers of TNF-[alpha] expressing cells. Thus, we found no evidence for an important role of TNF[alpha]-308 polymorphism for genetic susceptibility to MS.

Hewett, S. J., T. P. Misko, et al. (1996). "Murine encephalitogenic lymphoid cells induce nitric oxide synthase in primary astrocytes." Journal of Neuroimmunology **64**(2): 201.

<http://www.sciencedirect.com/science/article/B6T03-3VXHJX1-D/2/eeb3c53904ce561b0cb253ab169fe335>

A cytokine-inducible form of nitric oxide synthase (iNOS), capable of producing large quantities of nitric oxide (NO), can be induced in many cell types. We demonstrate that conditioned medium from encephalitogenic myelin basic protein-sensitized lymphoid cells (MBP-CM) induces the expression of iNOS in primary cultures of murine astrocytes in a time- and concentration-dependent manner. iNOS mRNA was detected by reverse transcriptase-polymerase chain reaction (RT-PCR) as early as 3 h post-exposure. Accumulation of nitrite into the astrocyte culture medium, an indirect measure of NO, was measurable 3 h post-exposure, plateaued at 24 h, and was prevented by the simultaneous administration of the NOS inhibitors, -NG-nitroarginine methyl ester, NG-nitro--arginine or aminoguanidine. Astrocyte expression of iNOS protein, detected by immunohistochemistry and immunoprecipitation/Western blot, was prevented by inhibitors of RNA or protein metabolism, consistent with its dependence on de novo protein synthesis.

Horiuchi, Y., T. Fujii, et al. (2003). "The endogenous, immunologically active peptide apelin inhibits lymphocytic cholinergic activity during immunological responses." Journal of Neuroimmunology **144**(1-2): 46.

<http://www.sciencedirect.com/science/article/B6T03-49W2KP6-4/2/b9052cc9ad50e308cefb0615d3f156b6>

We investigated the effects of apelin, an immunologically active peptide ligand for orphan receptor APJ, on acetylcholine (ACh) synthesis in MOLT-3 human leukemic T cells. We initially confirmed expression of APJ mRNA in several human T- and B-cell lines by reverse transcription-polymerase chain reaction (RT-PCR). We also found that in phytohemagglutinin (PHA)-stimulated MOLT-3 cells, an active apelin fragment, apelin-13, down-regulates expression of choline acetyltransferase (ChAT) mRNA and significantly reduces ChAT activity and cellular ACh content and release. It thus appears that apelin inhibits lymphocytic cholinergic activity via APJ during immunological responses.

House, S. D., X. Mao, et al. (2001). "Chronic morphine potentiates the inflammatory response by disrupting interleukin-1[beta] modulation of the hypothalamic-pituitary-adrenal axis." Journal of Neuroimmunology **118**(2): 277.

<http://www.sciencedirect.com/science/article/B6T03-43N673R-B/2/69b056794a9c791b29b84ae0c65a8b1e>

Interleukin-1-beta (IL-1[beta]) can promote inflammation by up-regulating vascular adhesion molecules and inhibit inflammation by activating the hypothalamic-pituitary-adrenal (HPA) axis to produce anti-inflammatory glucocorticoids. In this study, chronic morphine was shown to suppress IL-1[beta]-induction of corticotropin releasing factor (CRF) mRNA and plasma corticosterone levels. Leukocyte-endothelial adhesion (LEA) in rat mesenteric venules increased during IL-1[beta]- and FMLP-induced inflammation. Chronic morphine potentiated the LEA response to either IL-1[beta] or FMLP alone, and greatly enhanced LEA in response to combined IL-1[beta] and FMLP. Thus, it appears that chronic morphine exposure may promote a potentially damaging inflammatory reaction by disrupting the balance between IL-1[beta]-mediated local inflammation and the anti-inflammatory effects of the HPA axis.

Hvas, J., J. R. Oksenberg, et al. (1993). "[gamma][delta] T cell receptor repertoire in brain lesions of patients with multiple sclerosis." Journal of Neuroimmunology **46**(1-2): 225.

<http://www.sciencedirect.com/science/article/B6T03-47DKV NK-62/2/8821bee32de713ea71f69b1ea6917720>

The identification of activated T cells in the brains of patients with multiple sclerosis (MS) suggests that these cells are critical in the pathogenesis of this disease. Recently we have used the PCR method to analyse rearrangements of V[alpha] and V[beta] genes of the T cell receptor (TCR) in samples of MS and control brains. The results of these studies showed that TCR V gene usage in MS brains may be restricted and in particular that V[beta] genes may be preferentially rearranged in certain HLA haplotypes associated with susceptibility to MS. In view of the recent evidence that T lymphocytes bearing the [gamma][delta] chains may have autoreactive potential, we have assessed whether or not such TCR-bearing lymphocytes were also present in chronic MS lesions. TCR V[gamma] and V[delta] were analysed by the PCR method using a panel of V[gamma] and V[delta] primers paired with C[gamma] or C[delta] primers in 12 MS brains, as well as in brain samples of ten normal post-mortem cases and three neurological controls. TCR V[gamma]---C[gamma] and V[delta]---C[delta] rearrangements were confirmed using Southern blotting and hybridisation of the PCR products with specific C[gamma] and C[delta] probes. Only one to four rearranged TCR V[gamma] and V[delta] transcripts were detected in each of the 23 brain samples obtained from 12 MS patients, with the majority of [gamma][delta] T cells

expressing the V[gamma]2 and V[delta]2 chains. In marked contrast, V[gamma] and V[delta] transcripts could only be found in one of the ten non-neurological control brains analysed. To assess the clonality of V[gamma]2 and V[delta]2 T cell receptor chains in the brain samples of MS patients, we have sequenced the junctional regions of the TCR V[gamma]-N-J[gamma]-C[gamma] and V[delta]-N-D[delta]-N-J[delta]-C[delta] segments amplified from brain tissues, CSF and spleens of two MS patients and from the spleen of two control subjects. The sequence analysis obtained so far shows no compelling evidence of an MS specific expansion of one or more clones expressing particular types of [gamma][delta] T cell receptors. In contrast, a clonal expansion of a different population of TCR [gamma][delta]-bearing T cells was found in the spleen of both an MS patient and one of the control individuals. These results suggests that the [gamma][delta] T cell response at the site ohronic lesions, involve a number of clones, possibly in response to several inflammatory antigenic stimuli. Whether or not [gamma][delta] T cells are involved in the initiation of or in the chronicity of the disease remains to be elucidated.

Jander, S. and G. Stoll (1998). "Differential induction of interleukin-12, interleukin-18, and interleukin-1[beta] converting enzyme mRNA in experimental autoimmune encephalomyelitis of the Lewis rat." Journal of Neuroimmunology **91**(1-2): 93.

<http://www.sciencedirect.com/science/article/B6T03-3V5VDX7-D/2/80b7055b9e70e206cee62e3634637763>

Experimental autoimmune encephalomyelitis (EAE) is a model of autoimmune central nervous system (CNS) disease that is mediated by autoreactive Th1 cells secreting the proinflammatory cytokine interferon (IFN)-[gamma]. Interleukin (IL)-12 in its heterodimeric p35/p40 isoform and the recently described cytokine IL-18 potently induce T cell production of IFN-[gamma]. Interleukin-1[beta] converting enzyme (ICE) is required to convert IL-18 precursor protein into its biologically active mature form. In this study, we used semiquantitative reverse transcriptase-polymerase chain reaction to determine steady state levels of IL-12, IL-18, and ICE mRNA in the spinal cord of Lewis rats at different stages of EAE. In control rats, we found significant IL-18, ICE, and IL-12p35, but not IL-12p40 mRNA expression. IL-18 mRNA increased during the acute stage of EAE together with a marked induction of ICE mRNA. IL-12p35 mRNA levels did not change significantly throughout the course of EAE. Surprisingly, the peak expression of IL-12p40 mRNA was delayed by several days relative to the peak of T cell infiltration and IFN-[gamma] mRNA synthesis. Our data implicate the IL-18/ICE pathway in the amplification of Th1-mediated immune responses in the CNS but suggest a different, so far undefined role of endogenous IL-12 in the late effector phase of EAE.

Kim, J. S., S. C. Gautam, et al. (1995). "Expression of monocyte chemoattractant protein-1 and macrophage inflammatory protein-1 after focal cerebral ischemia in the rat." Journal of Neuroimmunology **56**(2): 127.

<http://www.sciencedirect.com/science/article/B6T03-3YYTF9M-2/2/2d2963a185399a09cb5d5220b36fcc35>

Chemoattractant cytokines, the chemokines, play an important role in early events of inflammation at the site of tissue damage. We examined the expression of mRNA and the protein products of two such chemokines; i.e. monocyte chemoattractant protein-1 (MCP-1) and macrophage inflammatory protein-1[alpha] (MIP-1[alpha]) in the ischemic brain tissue following middle cerebral artery occlusion (MCAo). The mRNA transcripts of MCP-1 and MIP-1[alpha] were detected by Northern hybridization and reverse transcriptase polymerase chain reaction (RT/PCR), respectively, and the anatomic distribution of specific proteins was analyzed by immunohistochemistry. We found that MCP-1 mRNA was not expressed in the brains of normal

rats or rats sacrificed 2 h after MCAo. 6 h after the induction of cerebral ischemia, weak expression of both mRNAs was detected in the ischemic tissue. mRNAs were expressed up to 48 h, and were markedly attenuated at 96 h. In the rats subjected to MCA occlusion, MCP-1 immunoreactivity was diffusely expressed and localized to the ischemic area, and was most intense at 48 h after MCA occlusion. Endothelial cells and macrophage-like cells expressed MCP-1 protein in the ischemic brain. The distribution and morphology of MIP-1[alpha] immunoreactive cells were identical with activated astrocytes. We conclude that MCP-1 and MIP-1[alpha] mRNAs and proteins are induced after cerebral ischemia in the rat. They may have a role in promoting inflammatory and/or repair processes in the ischemic brain, possibly by attracting or modulating inflammatory cells in the ischemic area.

Knezevic-Cuca, J., K. B. Stansberry, et al. (2000). "Neurotrophic role of interleukin-6 and soluble interleukin-6 receptors in N1E-115 neuroblastoma cells." Journal of Neuroimmunology **102**(1): 8.

<http://www.sciencedirect.com/science/article/B6T03-3Y9HBD2-2/2/8c2f02e244f65b8cde0a084abafd72b5>

Interleukin 6 (IL-6) plays a role in physiological and pathophysiological processes in neuronal cells. We studied whether IL-6 plays a role in neuroblastoma cells in culture. These studies demonstrate that N1E-115 cells constitutively express IL-6 but not IL-6R. Exogenous IL-6 stimulated neuronal proliferation in a dose-dependent manner. Under serum-free conditions soluble IL-6 receptors (sIL-6R) alone or in combination with IL-6 exerted significant proliferative effects, while IL-6 alone failed to promote cell proliferation. Neutralizing anti-IL-6 antibody caused a 30-40% reduction in IL-6 mediated proliferation. Our results suggest the importance of IL-6/sIL-6R for proliferation and survival of N1E-115 adrenergic neuroblastoma cells.

Kuhlmann, T., M. Glas, et al. (2002). "Investigation of bax, bcl-2, bcl-x and p53 gene polymorphisms in multiple sclerosis." Journal of Neuroimmunology **129**(1-2): 154.

<http://www.sciencedirect.com/science/article/B6T03-4689C4N-2/2/acf5a393657dde644ca220d75d448102>

Clinical course, outcome, radiological features, severity, and histopathology are heterogenous in multiple sclerosis (MS). Since MS is considered to be a polygenic disease, the genetic background may at least partly be responsible for this variability. Some MS cases are histopathologically characterized by a dramatic oligodendrocyte loss that is in part caused by apoptosis. A dysregulated apoptotic elimination of self-reactive T cells may also contribute to disease susceptibility. To analyze genetic differences in the apoptosis regulating factors bcl-2, bax, bcl-x and p53 we investigated polymorphisms of these genes in 105 patients with a relapsing remitting disease course and 99 controls by PCR-SSCP and direct sequencing. We identified so far unpublished sequence alterations in the promotor region of the bcl-x gene, in exon 7 of the p53 gene, and in exon 1 of the bax gene. No differences were observed between MS patients and controls. Additional known polymorphisms were found in intron 3 of the bax gene and in exon 6 of the p53 gene. No significant differences in the frequency of gene sequence variations were found between MS patients and controls. The apoptosis genes studied here therefore appear less likely to be important effector genes in MS.

Lai, J.-P., S. D. Douglas, et al. (1998). "Human lymphocytes express substance P and its receptor." Journal of Neuroimmunology **86**(1): 80.

<http://www.sciencedirect.com/science/article/B6T03-3SY8T41-9/2/daebd5f4ebc8841ef3dcd3420b6936fc>

We present data demonstrating the gene expression of substance P (SP) and its receptor in human peripheral blood-isolated lymphocytes. Using reverse transcribed polymerase chain reaction (RT-PCR) assay, preprotachykinin-A (substance-P) mRNA is detected in human peripheral blood-isolated lymphocytes. Among the [alpha], [beta] and [gamma] transcripts of the SP gene, only the [beta] and [gamma] transcripts are detectable in these cells. These RT-PCR amplified transcripts are recognized by Southern blot assay using a specific SP probe. Direct DNA sequence analysis of the RT-PCR products from lymphocytes also confirmed the structure of these transcripts which are identical to those found in human neuronal cells. At the protein level, human lymphocytes produced endogenous SP as determined by an enzyme immunoassay. Capsaicin, a vanillyl fatty acid amide (ingredient of hot pepper), released preformed SP from lymphocytes. In addition, using RT/nested-PCR analysis, we identified the presence of mRNA for neurokinin-1 receptor (the receptor for SP) in human peripheral blood-isolated lymphocytes, which was confirmed by Southern blot and DNA sequencing analysis. The demonstration that human lymphocytes express SP and its receptor support the notion that SP is biologically involved in regulating the functions of these cells in an autocrine fashion.

Lai, J.-P., S. D. Douglas, et al. (1998). "Identification of a [delta] isoform of preprotachykinin mRNA in human mononuclear phagocytes and lymphocytes." *Journal of Neuroimmunology* **91**(1-2): 121.

<http://www.sciencedirect.com/science/article/B6T03-3V5VDX7-J/2/b2b9491ec410b96ceefaa977379f576>

We have characterized preprotachykinin (PPT-A) gene transcript splicing products and identified a fourth isoform of PPT-A mRNA transcript in human peripheral blood-isolated monocytes and PBL. Using RT-PCR, Southern blot analysis and nucleotide sequencing analysis, we have identified the four isoforms of PPT-A transcripts ([alpha], [beta], [gamma] and [delta]) in human peripheral blood-isolated monocytes and PBL. The [delta]-PPT transcript present in the immune cells lacks exons 4 and 6. The sequences of exons 3, 5 and 7 of [delta]-PPT transcript completely match those of [beta]-PPT transcript. The [alpha]-PPT and [beta]-PPT sequences in these cells are identical to those obtained by Tan and Too (GenBank accession number U37539) and Harmar et al. (Genbank accession number X54469), but differ by a single nucleotide from another entry by Chiwakata et al. (Genbank accession number M68906). In comparison to this latter sequence, there was a C->T change at amino acid position 87 (CCT->CTT) which may result in a Pro to Leu change. Identification of the new SP mRNA transcript in both human CNS and immune cells supports the concept of an important biological link between CNS and immune system.

Lai, J.-P., W.-Z. Ho, et al. (2002). "A non-peptide substance P antagonist down-regulates SP mRNA expression in human mononuclear phagocytes." *Journal of Neuroimmunology* **128**(1-2): 101.

<http://www.sciencedirect.com/science/article/B6T03-46086CK-1/2/c6e2b0035303983d1751235ad108c96c>

Substance P (SP), a potent modulator of neuroimmunoregulation, exerts its activity by binding to the neurokinin-1 receptor (NK-1R). The SP-NK-1R interaction is important in inflammation and viral infections, including HIV infection of human immune cells. We recently demonstrated that SP modulates HIV replication and that a non-peptide SP antagonist CP-96,345 inhibits HIV replication in human monocyte-derived macrophages (MDM) by affecting the SP-NK-1R

interaction. In order to examine the effect of the SP antagonist on SP mRNA expression, MDM was incubated with or without CP-96,345 in the presence or absence of HIV infection. SP mRNA expression in these cells was then determined by real-time PCR technology. The effect of CP-96,345 on chemokine gene expression was also investigated by using a cDNA array assay. CP-96,345 down-regulated SP mRNA expression and antagonized exogenous SP-enhanced SP expression at the mRNA level, suggesting that SP autocrine regulation was interrupted by CP-96,345. CP-96,345 inhibited HIV replication in MDM, associated with down-regulated SP mRNA expression in comparison to HIV infection controls. In parallel with down-regulated SP and CCR5 mRNA expression, cDNA array assays indicated that CP-96,345 treatment also inhibited IL-8 gene expression, while enhancing expression of fractalkine and monocyte chemoattractant protein-3 (MCP-3). Since SP plays an important role in inflammation and viral infections, these studies may have potential applications for therapeutic intervention of inflammation and viral infection of immune cells.

Ledeboer, A., A. Wierinckx, et al. (2003). "Regional and temporal expression patterns of interleukin-10, interleukin-10 receptor and adhesion molecules in the rat spinal cord during chronic relapsing EAE." *Journal of Neuroimmunology* **136**(1-2): 94.

<http://www.sciencedirect.com/science/article/B6T03-481D7XS-6/2/faf7f318ae98dc163cc89f64ea767164>

Adhesion molecules intercellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1) mediate leukocyte infiltration into the CNS, in experimental autoimmune encephalomyelitis (EAE) and multiple sclerosis (MS). Because exogenous interleukin-10 (IL-10) inhibits ICAM-1 and VCAM-1 expression and clinical EAE, we hypothesize that endogenous IL-10 signaling may suppress expression of adhesion molecules. In a rat model of chronic relapsing EAE, expression levels of IL-10 and its receptor (IL-10R1), ICAM-1 and VCAM-1 mRNA in the spinal cord are markedly increased, whereas levels of IL-10 mRNA remain relatively low. The temporal pattern of mRNA and protein expression showed marked differences between spinal cord levels. During relapse, IL-10, IL-10R1, ICAM-1, VCAM-1 mRNA levels and neurological scores show positive correlations. We conclude that endogenous IL-10 is not a crucial factor inhibiting adhesion molecule expression in this model.

Li, Y., S. D. Douglas, et al. (2001). "Substance P enhances HIV-1 replication in latently infected human immune cells." *Journal of Neuroimmunology* **121**(1-2): 67.

<http://www.sciencedirect.com/science/article/B6T03-448FVSN-3/2/e120ffb63d3a1f11c1363831dd406bb2>

Substance P (SP) is a potent modulator of neuroimmunoregulation. SP receptors are present on human monocytes and T lymphocytes, and SP alters the function of these immune cells. We investigated the effects of SP on HIV-1 replication in latently infected human immune cells. SP significantly enhanced HIV-1 replication in the latently infected promonocytic cell line (U1) and T lymphocyte line (ACH-2) stimulated with tumor necrosis factor (TNF-[alpha]). When added to these cells in combination with TNF-[alpha], SP also enhanced HIV-1 gag gene expression in U1 and ACH-2 cells. This stimulatory effect of SP was associated with the activation of HIV-LTR (long terminal repeat) driven chloramphenicol acetyltransferase (CAT) gene expression, and could be blocked by pretreatment of U1 and ACH-2 cells with an SP receptor antagonist RP-67,580, indicating specific SP receptor-mediated regulation. Furthermore, the addition of SP to the cultures of latently infected peripheral blood mononuclear cells isolated from HIV-1-infected patients enhanced HIV-1 gag gene expression. Thus, SP may play a potentially important role as a positive regulator of HIV-1 replication in latently infected monocytes and lymphocytes. These

observations may have significant implications toward understanding the role of neuropeptide SP in the immunopathogenesis of HIV-1 infection and AIDS.

Liu, H.-C., J. K. Anday, et al. (2004). "Dual effects of morphine on permeability and apoptosis of vascular endothelial cells: morphine potentiates lipopolysaccharide-induced permeability and apoptosis of vascular endothelial cells." Journal of Neuroimmunology **146**(1-2): 13.

<http://www.sciencedirect.com/science/article/B6T03-4B4S3HG-1/2/902aea9ea50d23c1cda6c7cd54ab12c2>

Vascular endothelial cells (VEC) provide an essential protective barrier between the vascular system and underlying tissues. Using VEC barrier models of human coronary artery cells and human and rat brain microvascular endothelial cells, we investigated the mechanism by which morphine affects lipopolysaccharide (LPS)-induced VEC permeability. We demonstrated that co-administration of morphine and LPS induced greater VEC apoptosis and permeability than morphine or LPS alone. The extent of induced apoptosis appeared to be cell-type dependent. Furthermore, RT-PCR analysis revealed that morphine and LPS up-regulated Fas expression. These data suggest potential crosstalk between the signaling pathways that mediate morphine- and LPS-triggered apoptosis in brain VEC.

Maier, C. C., R. D. LeBoeuf, et al. (1993). "The structure of a myelin basic protein-associated idiotope." Journal of Neuroimmunology **46**(1-2): 235.

<http://www.sciencedirect.com/science/article/B6T03-47DKV NK-63/2/34c8e5bc7369ca1dc148997476723333>

A cross-reactive idiotope (CRI) has been previously described on monoclonal antibodies (mAbs) specific for encephalitogenic peptides from myelin basic protein (MBP). The anti-CRI mAb, F25F7, binds an idiotope (Id) localized to the light chains of an anti-MBP peptide 1-9 mAb, denoted F23C6, and an anti-MBP peptide 80-89 mAb, denoted 845D3. It is the purpose of this study to further delineate the CRI being recognized by F25F7. To this end, we have found a structural correlation between the CRI and the antigen, a small synthetic peptide, denoted PBM 9-1, used to elicit the anti-Id mAb. Sequence comparison between the light chain of F23C6 and PBM 9-1 reveals a region of homology in CDR 2/FWK 3. The configuration of this site in the VL, as determined by comparison with a mAb, HyHEL-10, whose structure has been determined and is 97% homologous to the light chain of F23C6, conforms to the rules used to define antigenic determinants or Ids. A synthetic peptide having the F23C6 VL CDR 2/FWK 3 sequence inhibited the binding of F25F7 to F23C6 and 845D3. Taken together, these data suggest the Id recognized by F25F7 is defined, in part, by the PBM 9-1-like sequence of F23C6.

Makarenkova, V. P., G. V. Shurin, et al. (2003). "Lung cancer-derived bombesin-like peptides down-regulate the generation and function of human dendritic cells." Journal of Neuroimmunology **145**(1-2): 55.

<http://www.sciencedirect.com/science/article/B6T03-4B3DT8W-5/2/d16ed0c758f9f3264d818f4596979c80>

Development of tumors is regulated by tumor-derived neuroendocrine factors, including bombesin-like peptides (BLP). We have evaluated neuroendocrine regulation of dendritic cell

(DC) maturation and function by both tumor-derived and purified bombesin (BOM), neuromedin B (NMB), gastrin-releasing peptide (GRP), and a BOM antagonist -Phe-bombesin (DPB). BOM, NMB and GRP dose-dependently inhibited maturation of DC assessed as down-regulation of CD40, CD80 and CD86 expression on DC. BOM and GRP also inhibited interleukin-12 (IL-12) production by DC and their ability to activate T cells. DPB partly abrogated immunosuppressive effect of tumor cells on DC. These data are a first evidence for the role of BLP in the regulation of DC maturation and function, demonstrating that BLP inhibit DC maturation and longevity in the lung cancer microenvironment. This suggests a new mechanism of tumor escape and provides new targets for the immunopharmacological correction of immune effectors in cancer.

Matsubara, S., T. Kitaguchi, et al. (2001). "Experimental allergic myositis in SJL/J mouse. Reappraisal of immune reaction based on changes after single immunization." Journal of Neuroimmunology **119**(2): 223.

<http://www.sciencedirect.com/science/article/B6T03-442XPR6-9/2/942b312a2a6e902590e3561b9fedd268>

SJL/J mice have been subjected to immunization with wide varieties of antigens to produce models of autoimmune disorders including experimental myositis. They also have a defect in dysferlin gene and spontaneously develop muscle fiber degeneration, a condition akin to limb-girdle type muscular dystrophy and Miyoshi myopathy. To know whether muscle inflammation of SJL mice after immunization with muscle fractions really represents immune-mediated myositis or no more than an epiphenomenon of muscle degeneration due to dysferlin defect, we studied immunological parameters after immunization with rabbit myosin B fraction. Initial infiltration of macrophages and CD4+ lymphocytes on day 11 was followed by increase in number of CD8+ cells. Such increase was not observed in the nontreated and adjuvant controls. Some infiltrating cells were interferon gamma (IFN-[gamma]) positive. Furthermore, increased expression of the signal transducers and activator of transcription 1 (STAT-1) and interferon regulatory factor 1 (IRF-1) mRNA was shown in the first 2 weeks. These results indicate Th1 system activity in the muscle, rather than simple dysferlin deficiency, particularly 1-3 weeks after immunization. Thus it is concluded that an immune-mediated myositis is taking place at this stage. This model can be helpful in understanding pathomechanisms involved in the early stage of human myositides. It has also important implications concerning immune reactions associated with transplantation or gene therapy for muscular dystrophies.

Matsumoto, Y., G. Kim, et al. (2000). "Characterization of T cell receptor associated with the development of P2 peptide-induced autoimmune neuritis." Journal of Neuroimmunology **102**(1): 67.

<http://www.sciencedirect.com/science/article/B6T03-3Y9HBD2-9/2/c724221608fce2ee1ed62e728471e419>

To characterize experimental autoimmune neuritis (EAN)-inducing T cells in more detail, we performed CDR3 spectratyping analysis and found oligoclonal expansion of several V[beta] spectratypes in nerve-infiltrating T cells. V[beta]5 expansion was observed all the stages examined, whereas V[beta]8.2 and V[beta]17 expansion was mainly found at the peak and preclinical stages, respectively. Since V[beta]5 expansion persists throughout the course of the disease, V[beta]5+ T cells are judged to be the main effector cells. V[beta]8.2+ and V[beta]17+ T cells may also be pathogenic but are not the main effectors because expansion of these spectratypes was found at a limited period of time. Sequence analysis revealed that V[beta]5, V[beta]8.2 and V[beta]17 spectratype-derived TCR clones possess their own dominant sequences in the CDR3 region with no homology among the clones. These findings suggest that polyclonally activated T cells are involved in the formation of the nerve lesion. Furthermore,

vaccination with V[beta]5 DNA, but not with V[beta]10 DNA, suppressed the development of EAN significantly. Collectively, these findings indicate that determination of autoimmune disease-associated TCR by CDR3 spectratyping provides useful information for designing TCR-based immunotherapy for the disease.

Misko, T. P., J. L. Trotter, et al. (1995). "Mediation of inflammation by encephalitogenic cells: interferon [gamma] induction of nitric oxide synthase and cyclooxygenase 2." Journal of Neuroimmunology **61**(2): 195.

<http://www.sciencedirect.com/science/article/B6T03-3YYV2B2-B/2/3e1c7e2d7e5d1107b0ddf10e3a975d1d>

Experimental autoimmune encephalomyelitis (EAE) is a T cell-mediated inflammatory demyelinating disorder of the central nervous system (CNS) which serves as a prime animal model for the human disease multiple sclerosis. Previous studies from these laboratories demonstrated excess nitric oxide (NO) in the CNS of EAE-affected mice, and amelioration of EAE with a selective inhibitor of the inducible nitric oxide synthase (iNOS). Recent studies from other laboratories have indicated that prostaglandin PGE₂ is increased in CNS tissues of EAE-affected rodents and that EAE is prevented by the inhibition of cyclooxygenase activity. The present study investigated the ability of encephalitogenic lymphoid cells to induce NOS and cyclooxygenase (COX-2) in the murine macrophage line, RAW 264.7. In order to mimic the extracellular milieu present in EAE lesions, conditioned medium (CM) of activated EAE-inducer cells was added to this macrophage line. CM caused a time-dependent increase in nitrite, indicating NO production. Reverse-transcriptase PCR demonstrated iNOS mRNA in RAW 264.7 cells, first detected at 3 h, and Western blots confirmed the induction in RAW cells of the 130-kDa iNOS protein. Production of nitrite by CM-exposed RAW 264.7 cells was blocked by inhibitors of NOS (-N-methylarginine or aminoguanidine) or by antibodies to murine IFN-[gamma] or IL-1[beta]. CM of activated encephalitogenic cells induced production of PGE₂ by RAW 264.7 cells, as determined by ELISA, and Western blots identified the presence of the 70-80-kDa inducible COX (COX-2) protein. Induction of COX-2 could be inhibited by antibody to IFN-[gamma]. Thus, encephalitogenic cells are capable of inducing the expression of the inflammatory enzymes iNOS and COX-2 in a murine macrophage line via the T cell cytokine IFN-[gamma], alone or in combination with IL-1[beta].

Niino, M., S. Kikuchi, et al. (2003). "Genetic polymorphisms of osteopontin in association with multiple sclerosis in Japanese patients." Journal of Neuroimmunology **136**(1-2): 125.

<http://www.sciencedirect.com/science/article/B6T03-47S6Y27-2/2/b63cf65b11e7e4d06b9f0ae7f6439f01>

Osteopontin (OPN) exhibits pleiotropic functions and abundant transcripts for OPN are present in brains of patients with multiple sclerosis (MS). The aim of this study was to investigate the role of OPN genes in the pathogenesis of MS. Polymorphisms at the 8090th, 9250th and 9583rd positions in OPN were detected by PCR-RFLP from DNAs of 116 MS Japanese patients and 124 healthy controls. The C/C genotype at the 8090th position in exon 6 was more prevalent in MS than in control (p=0.01) and A/A (age; 25.2±8.9 years, p=0.01) genotypes. There were no significant correlations between OPN gene polymorphisms and disease progression. Our results suggest that the 8090th polymorphism might be associated with susceptibility to MS, while the 9583rd polymorphism might be associated with age of onset of MS.

Omari, K. I. M. and K. Dorovini-Zis (2001). "Expression and function of the costimulatory molecules B7-1 (CD80) and B7-2 (CD86) in an in vitro model of the human blood-brain barrier." Journal of Neuroimmunology **113**(1): 129.

<http://www.sciencedirect.com/science/article/B6T03-41Y28FP-G/2/d5a182e24ffe4bbb2470d32971e36a9e>

The interaction of B7 molecules with their ligand provides important accessory signals for optimal T cell activation and proliferation. In this study the in vitro expression of B7-1 and B7-2 by human brain microvessel endothelial cells (HBMEC) was investigated by semiquantitative reverse transcriptase-polymerase chain reaction (RT-PCR) and immunocytochemistry. In addition, the contribution of B7 molecules to T cell proliferation on cerebral endothelial cells was studied by coincubating purified CD4+ T cells with resting or cytokine activated HBMEC. Untreated cultures constitutively expressed B7-2 RNA and surface protein, but lacked B7-1 expression. Treatment with TNF-[alpha] and IFN-[gamma] upregulated B7-2 and induced de novo expression of B7-1. Monoclonal blocking antibodies to B7-1 or B7-2 and human CTLA-4Ig chimeric protein significantly reduced the ability of HBMEC to support [alpha]-CD3-induced proliferation of CD4+ T lymphocytes. Expression of B7 glycoproteins and the ability to provide secondary signals for T cell proliferation suggest a potential role of the human cerebral endothelium in T cell activation during the early stages of central nervous system inflammation.

Omari, K. M. and K. Dorovini-Zis (2003). "CD40 expressed by human brain endothelial cells regulates CD4+ T cell adhesion to endothelium." Journal of Neuroimmunology **134**(1-2): 166.

<http://www.sciencedirect.com/science/article/B6T03-47CXW39-2/2/7eada645c7068bf95570aeb37140eaf8>

Recent evidence suggests that interactions between CD40 on antigen presenting cells (APC) and CD40L on T cells generate signals that result in the activation of APC. In this study, the expression and function of CD40 was investigated in primary cultures of human brain microvessel endothelial cells (HBMEC). Results revealed constitutive expression of CD40 on untreated HBMEC. Stimulation with TNF-[alpha], IFN-[gamma], LPS or combination of TNF-[alpha] and IFN-[gamma] significantly upregulated CD40. The majority of CD40 molecules were localized on the apical surface of EC. Incubation of HBMEC with soluble CD40L resulted in increased expression of the adhesion molecules E-selectin, VCAM-1 and ICAM-1. Consequently, the adhesion of both resting and anti-CD3 activated CD4+ T lymphocytes to CD40L treated HBMEC was significantly increased compared to unstimulated EC. The expression of CD40 by cerebral endothelium, and endothelial cell activation following binding of CD40 to its ligand, CD40L, suggest a potential mechanism by which activated CD40L expressing T cells could enhance adhesion and migration of inflammatory cells across the blood-brain barrier (BBB) to sites of inflammation in the human central nervous system (CNS).

Palma, C. and S. Manzini (1998). "Substance P induces secretion of immunomodulatory cytokines by human astrocytoma cells." Journal of Neuroimmunology **81**(1-2): 127.

<http://www.sciencedirect.com/science/article/B6T03-3S4PGS1-H/2/cf62cd33062e1a6661c493fd9e912715>

In human astrocytoma cell lines, substance P (SP) stimulated interleukin (IL)-8, IL-6, granulocyte macrophage colony-stimulating factor and leukemia inhibitory factor protein secretion. These SP effects were blocked by a specific NK1 tachykinin receptor antagonist. Further, SP stimulation

increased the half-life of IL-6 and IL-8 messenger RNAs, suggesting that the synthesis of these cytokines is also regulated post-transcriptionally. SP-induced cytokine release was inhibited by staurosporine and phorbol 12-myristate 13-acetate desensitization suggesting protein kinase C involvement. The demonstration that SP affects cytokine production in glioma cells might be of relevance for the biology of such tumors.

Palma, C., F. Urbani, et al. (1995). "Interleukin-6 production by U373 MG, a human astrocytoma cell line: different pathways involved in substance P and lipopolysaccharide activation." Journal of Neuroimmunology **59**(1-2): 155.

<http://www.sciencedirect.com/science/article/B6T03-3YYTVJM-K/2/07176691abda11a44b8feb2e534caf73>

Substance P (SP) and lipopolysaccharide (LPS) stimulated interleukin-6 (IL-6) gene expression, as well as IL-6 protein secretion in the human astrocytoma cell line U373 MG. Staurosporine, an inhibitor of protein kinase C (PKC), entirely blocked SP- but not LPS-induced IL-6 release. In addition, the down regulation of PKC inhibited the SP response and only marginally altered LPS activation. Differently from SP, LPS-induced IL-6 release was markedly reduced by W7, a calmodulin antagonist. Moreover, SP interacted in a synergistic manner with LPS. Thus, neural (SP) and bacterial (LPS) mediators stimulate U373 MG IL-6 release via distinct, though not antagonistic, activation pathways.

Petitto, J. M. and Z. Huang (1995). "Molecular cloning of the coding sequence of an interleukin-2 receptor [alpha] subunit cDNA in murine brain." Journal of Neuroimmunology **59**(1-2): 135.

<http://www.sciencedirect.com/science/article/B6T03-3YYTVJM-H/2/b54e85b6fcf908dd0ca891bb412fad69>

Interleukin-2 (IL-2) has various trophic and neuromodulatory actions in the mammalian central nervous system (CNS). The interleukin-2 receptor [alpha] (IL-2R[alpha]) is an accessory subunit of the IL-2 receptor heterotrimer complex which is essential for 'high' affinity IL-2 binding. Although an IL-2R[alpha] (or IL-2Ra-like) epitope has been localized in brain by immunohistochemistry, it was unknown whether the IL-2R[alpha] subunit expressed in-brain was derived from the same or a different gene than the lymphocyte IL-2R[alpha]. Therefore, in the present study, the cDNA comprising the full length coding region was cloned and sequenced from saline-perfused forebrain. The brain IL-2R[alpha] cDNA was found to be 100% homologous with the corresponding lymphocyte IL-2R[alpha] cDNA sequence. IL-2R[alpha] mRNA was expressed at very low levels in saline-perfused forebrain of non-challenged BALB/c mice as well as in saline-perfused forebrain from severe combined immunodeficiency (SCID) mice. The present data, demonstrating IL-2R[alpha] gene expression in both well-perfused normal and SCID mouse forebrain from which no CD3[gamma] gene expression was detected by PCR, provides evidence that the IL-2R[alpha] clones isolated are from resident brain cells and not from blood lymphocytes (e.g. T lymphocytes). Thus, these findings demonstrate that the protein coding sequence of the mouse brain IL-2R[alpha] is derived from the same gene coding sequence as the lymphocyte IL-2R[alpha], and indicate that previously reported differences in the size of their respective mRNA transcripts appear to be due to differences in untranslated regions.

Petitto, J. M., Z. Huang, et al. (1994). "Molecular cloning of NPY-Y1 receptor cDNA from rat splenic lymphocytes: Evidence of low levels of mRNA expression and [125I]NPY binding sites." Journal

of *Neuroimmunology* **54**(1-2): 81.

<http://www.sciencedirect.com/science/article/B6T03-47DKSSM-13/2/387a5ebe6f988fcbc17da518f07694d5>

The present study addressed the question of whether the effects of neuropeptide Y (NPY) on parameters of cellular immune activity are mediated by the direct action of this neuropeptide on lymphocyte NPY receptors. A partial cDNA corresponding to bp 3-585 of the NPY-Y1 receptor coding sequence was cloned from rat splenic lymphocytes and found to have 100% nucleotide sequence homology with that segment of the NPY-Y1 receptor in brain. Basal levels of NPY-Y1 mRNA expression and [¹²⁵I]NPY binding sites of rat splenic lymphocytes were markedly lower than in frontal cortex. These data provide the first direct evidence that cells of the immune system possess NPY receptors, and suggest that further study will be necessary to determine their physiological significance.

Piraino, P. S., T. A. Yednock, et al. (2002). "Prolonged reversal of chronic experimental allergic encephalomyelitis using a small molecule inhibitor of [alpha]4 integrin." *Journal of Neuroimmunology* **131**(1-2): 147.

<http://www.sciencedirect.com/science/article/B6T03-46WV6NX-5/2/d20dbd5381c8a439d0c599c6e358282f>

CNS leukocytic invasion in experimental allergic encephalomyelitis (EAE) depends on [alpha]4[beta]1 integrin/vascular cell adhesion molecule-1 (VCAM-1) interactions. A small molecule inhibitor of [alpha]4[beta]1 integrin (CT301) was administered to guinea pigs in the chronic phase (>d40) of EAE for 10, 20, 30 or 40 days. CT301 elicited a rapid, significant improvement in the clinical and pathological scores that was maintained throughout the treatment period. A progressive loss of cells in the spinal cord of treated animals confirmed the resolution of inflammation associated with clinical recovery. Therefore, prolonged inhibition of [alpha]4[beta]1 integrin caused a sustained reversal of disease pathology in chronic EAE and may be similarly useful in MS.

Poluektova, L., T. Moran, et al. (2001). "The regulation of alpha chemokines during HIV-1 infection and leukocyte activation: relevance for HIV-1-associated dementia." *Journal of Neuroimmunology* **120**(1-2): 112.

<http://www.sciencedirect.com/science/article/B6T03-449TY7W-G/2/4e3b51812120860e70b47c74102e8f2c>

Cellular immunity against human immunodeficiency virus type 1 (HIV-1)-infected brain macrophages serves to prevent productive viral replication in the nervous system. Inevitably, during advanced disease, this antiretroviral response breaks down. This could occur through virus-induced dysregulation of lymphocyte trafficking. Thus, we studied the production of non-ELR-containing [alpha]-chemokines and their receptor (CXCR3) expression in relevant virus target cells. Macrophages, lymphocytes, and astrocytes secreted [alpha]-chemokines after HIV-1 infection and/or immune activation. Lymphocyte CXCR3-mediated chemotactic responses were operative. In all, [alpha]-chemokine-mediated T cell migration continued after HIV-1 infection and the neuroinflammatory events operative during productive viral replication in brain.

Reiseter, B. S., G. T. Miller, et al. (1998). "Treatment of murine experimental autoimmune encephalomyelitis with a myelin basic protein peptide analog alters the cellular composition of leukocytes infiltrating the cerebrospinal fluid." Journal of Neuroimmunology **91**(1-2): 156.

<http://www.sciencedirect.com/science/article/B6T03-3V5VDX7-P/2/516c59d6881d06c6ef64fe9006bf325e>

Experimental autoimmune encephalomyelitis (EAE) can be effectively treated during disease exacerbation by administration of a peptide corresponding to the major T cell epitope of myelin basic protein (MBP), but the mechanism by which T cell tolerance leads to clinical improvement is not well-defined. Acute exacerbations of EAE are accompanied by an infiltration of blood-borne leukocytes into the brain and spinal cord, where they mediate inflammation and demyelination. To investigate peptide effects on infiltrating cells, we collected cerebrospinal fluid (CSF) from (PL/JxSJL)F1 mice with MBP-induced EAE. Pleiocytosis by lymphocytes, neutrophils, and macrophages was seen throughout the course of relapsing-remitting disease. A single administration of the MBP peptide analog, Ac1-11[4Y], reduced disease severity, accompanied by a dramatic and selective loss of neutrophil pleiocytosis. A longer course of peptide therapy resulted in complete recovery from clinical signs of disease, and decreased pleiocytosis by all cell types. Clinical severity throughout the course of disease and therapy was directly related to the degree of infiltration by neutrophils and macrophages, and the clinical improvement following peptide therapy was accompanied by decreased central nervous system (CNS) expression of chemoattractants for these cell types. These observations support a model of disease exacerbation mediated by phagocytic cellular infiltration under the ultimate control of T cell-derived factors, amenable to treatment by down-regulation of the T cell activation state.

Ringheim, G. E., K. L. Burgher, et al. (1995). "Interleukin-6 mRNA expression by cortical neurons in culture: Evidence for neuronal sources of interleukin-6 production in the brain." Journal of Neuroimmunology **63**(2): 113.

<http://www.sciencedirect.com/science/article/B6T03-4002J1P-2/2/128eb0f2ac84f4279cd746e0cad090b1>

In this study, we investigated the capacity of murine cortical neurons to express interleukin-6 (IL-6) mRNA and protein in culture. Using in situ hybridization techniques, IL-6 mRNA was localized to neuronal cells in these cultures. Moreover, IL-6 mRNA expression as measured by in situ and PCR was shown to be upregulated by the proinflammatory cytokines interleukin-1[beta] (IL-1[beta]) and tumor necrosis factor-[alpha] (TNF-[alpha]). This was consistent with the dose and time-dependent increases in IL-6 secreted protein observed from cultures stimulated with IL-1[beta] and TNF-[alpha]. Taken together, the data suggest that neurons are capable of participating more directly in the CNS cytokine network than previously thought and may play an important role in the inflammatory response activities in the brain.

Rinner, I., K. Kawashima, et al. (1998). "Rat lymphocytes produce and secrete acetylcholine in dependence of differentiation and activation." Journal of Neuroimmunology **81**(1-2): 31.

<http://www.sciencedirect.com/science/article/B6T03-3S4PGS1-4/2/37cf97457a69535fa892f82f0abb6ce4>

Previous data from this laboratory suggested for the first time that immune cells of the immune system of different species are capable to synthesize the neurotransmitter acetylcholine. In the present study we detected the RNA message for choline acetyltransferase in thymic, splenic and

peripheral blood lymphocytes of rats using RT-PCR. Furthermore, using a sensitive radioimmunoassay, we measured acetylcholine in thymic, splenic and peripheral blood lymphocytes. T-cells were found to contain about three times the amount of acetylcholine as compared to B-cells, and CD4⁺ cells showed significantly higher levels as compared to CD8⁺ cells. Mitogenic stimulation with PHA increased the acetylcholine levels in lymphoid cells as well as the release into the supernatants.

Rosche, B., S. Cepok, et al. (2004). "The role of the Polio Virus Receptor and the Herpesvirus entry mediator B genes for the development of MS." Journal of Neuroimmunology **156**(1-2): 171.

<http://www.sciencedirect.com/science/article/B6T03-4D4D5VY-1/2/d50cc01ad92cea05ca6032c1eff9f0d2>

Multiple sclerosis (MS) is a chronic inflammatory and demyelinating disease of the central nervous system (CNS). Although the cause of MS is still uncertain, it is well accepted that both genetic and environmental factors are important for the development of disease. In this study, we focused on the Polio Virus Receptor (PVR) and Herpesvirus entry mediator B (HVEB) receptor genes, which are located on chromosome 19q13, a region previously linked to MS. Both receptors are expressed in the brain and immune system and play an important role for inter-cellular adhesion and entry of neurotropic viruses to the brain. We identified four new polymorphisms in the PVR gene, which were located in the promoter region and three different exons. All exonic polymorphisms altered the amino acid sequence of the receptor. No new polymorphisms were found in the HVEB gene, but we confirmed a previously identified intronic polymorphism. We analyzed the frequency of the polymorphisms by RFLP analysis in sporadic MS patients, MS families, and healthy controls and determined the surface expression of HVEB and PVR on peripheral blood monocytes. We did not find differences in the frequency of the polymorphisms or surface expression between MS patients and controls. Overall, our findings do not support a role of HVEB and PVR genes in the development of MS.

Roupe van der Voort, C., C. J. Heijnen, et al. (2000). "Stress induces increases in IL-6 production by leucocytes of patients with the chronic inflammatory disease juvenile rheumatoid arthritis: a putative role for [alpha]1-adrenergic receptors." Journal of Neuroimmunology **110**(1-2): 223.

<http://www.sciencedirect.com/science/article/B6T03-41C2RJC-W/2/17d44ec4c8811b10166b07f41bd657ca>

Juvenile rheumatoid arthritis (JRA) is characterized by chronic inflammation of the joints. In the present study we demonstrate that exposure of JRA patients to a noradrenergic stressor (cold pressor test) results in enhanced LPS-induced IL-6 production by peripheral blood cells of these patients. Healthy, age-matched controls had the same rise in norepinephrine, but do not respond with changes in IL-6 production after exposure to the cold pressor test. Moreover, PBMC of patients with JRA express mRNA encoding [alpha]1-adrenergic receptors (AR), predominantly of the [alpha]1d-AR subtype. In contrast, we could not detect mRNA encoding for [alpha]1-AR in PBMC of healthy controls. The results of this study suggest that expression of [alpha]1-AR mRNA in PBMC during chronic inflammation is associated with altered responses of the immune system to stress.

Roupe van der Voort, C., A. Kavelaars, et al. (1999). "Neuroendocrine mediators up-regulate [alpha]1b- and [alpha]1d-adrenergic receptor subtypes in human monocytes." Journal of Neuroimmunology

95(1-2): 165.

<http://www.sciencedirect.com/science/article/B6T03-3W4B1W0-M/2/3ce0eaf25fca4acc3d71a5e0c63d5a7b>

[beta]2- and [alpha]2-adrenergic receptors (AR) are thought to be the main AR subtypes to exert the effects of catecholamines on the immune system. However, in the present study, we demonstrate that another subtype of AR can be induced in human monocytes. Expression of [alpha]1b- and [alpha]1d-AR mRNA can be obtained by culturing freshly isolated human peripheral blood monocytes with the neuroendocrine mediators dexamethasone or the [beta]2-AR agonist terbutaline. Using the human monocytic cell line THP-1, we demonstrate that increased levels of [alpha]1b- and [alpha]1d-mRNA are accompanied by increased levels of receptor protein as determined by Western blot analysis and radioligand binding assays. This study describes for the first time regulated expression of [alpha]1-AR subtypes in human monocytes.

Roupe van der Voort, C., A. Kavelaars, et al. (2000). "Noradrenaline induces phosphorylation of ERK-2 in human peripheral blood mononuclear cells after induction of [alpha]1-adrenergic receptors." *Journal of Neuroimmunology* **108**(1-2): 82.

<http://www.sciencedirect.com/science/article/B6T03-40R5BF6-C/2/7f8f3b439bff5ea69989c29fc7c53c5>

[alpha]1-Adrenergic receptors (ARs) are not expressed by peripheral blood mononuclear cells (PBMCs) of healthy human individuals. However, in the present study we show that [alpha]1-ARs can be induced in lymphocytes after culturing with either the mitogen PHA or the glucocorticoid dexamethasone. Moreover, incubation of these activated PBMCs with noradrenaline (NA) results in enhanced phosphorylation of ERK-2, a kinase involved in the activation of many immune functions. Similar induction of [alpha]1-AR mRNA with concomitant NA-induced activation of ERK-2 occurs in monocytes after culture with LPS. Our results demonstrate that functional [alpha]1-ARs can be induced on PBMCs and that these [alpha]1-ARs mediate NA-induced activation of ERK-2.

Roy, S., R. G. Charboneau, et al. (1999). "Morphine synergizes with lipopolysaccharide in a chronic endotoxemia model." *Journal of Neuroimmunology* **95**(1-2): 107.

<http://www.sciencedirect.com/science/article/B6T03-3W4B1W0-C/2/d135b0b84fd31c2d702400ce37fcb24>

Emergent or elective surgical procedures may be complicated by sepsis, resulting in critical illness that can lead to organ failure and death. The opioid drug, morphine is widely used to alleviate pain in post-surgical patients; however, it is well documented that chronic treatment of mice with morphine affects the proliferation, differentiation and function of immune cells. Thus, morphine might be expected to exacerbate the effects of sepsis, which also compromises the immune system. To test this notion, we investigated the effect on several immune functions of a clinical dose of morphine (4 mg/kg) superimposed upon a lipopolysaccharide (LPS)-induced infection model. Our results show that this relatively low dose of morphine, though generally having no effects on immune parameters by itself, significantly augmented LPS responses. A clinical dose of morphine (4 mg/kg body weight) superimposed upon an animal model of sepsis resulted in a significant increase in mortality at 48 h. In the absence of the drug, most septic animals died after 96 h. Phenotypic responses such as, decreased thymic cellularity, compromised mitogenic response and inhibition of IL-2 synthesis that are evident at 48-72 h after

LPS injection appear as early as 24 h in animals that receive morphine in addition to LPS. In addition, our results show that in T cells there is a shift from TH1 type cytokine elaboration to a TH2 type cytokine elaboration in animals that receive both LPS and morphine.

Sato, S., S. L. Reiner, et al. (1997). "Central nervous system cytokine mRNA expression following Theiler's murine encephalomyelitis virus infection." Journal of Neuroimmunology **76**(1-2): 213.

<http://www.sciencedirect.com/science/article/B6T03-3PSB1XD-Y/2/aeffadb4e512d063b5dc934a0010bbe3>

DA strain of Theiler's murine encephalomyelitis virus (TMEV) produces a biphasic disease with an initial self-limited acute gray matter polioencephalomyelitis in all strains of mice followed by, in the case of certain susceptible strains of mice, a chronic inflammatory demyelination of the spinal cord with a persistent virus infection. A pathogenic role for T-helper 1 (Th1) cells during the demyelinating phase of disease has been proposed. We characterized the cytokine mRNA expression in the brain and spinal cord of susceptible and resistant strains of mice during the early encephalomyelitic disease and the late demyelination, using a semi-quantitative reverse transcription-polymerase chain reaction (RT-PCR) assay. At the time of the encephalomyelitis, both resistant and susceptible mice expressed proinflammatory cytokine mRNAs followed by T-cell derived mRNAs; susceptible mice expressed more IL-12 p40 mRNA than resistant mice. During this early disease, there was no significant difference in Th1 cytokine mRNA expression in the brain and spinal cord among the four strains and relatively little Th2 type cytokine upregulation above levels seen in mock-infected controls. During the late demyelinating disease, susceptible but not resistant mice had evidence of viral genome and a continuous expression of Th1 type cytokine mRNAs. The expression of Th2 cytokine mRNAs varied among the different strains and did not correlate with susceptibility or resistance. The results indicate the complexity of cytokine mRNA expression following TMEV infection and the dependence of the expression on disease pathology, the time following infection and the genetics of the host.

Schaecher, K. E., J.-M. Goust, et al. (2001). "The effects of calpain inhibition upon IL-2 and CD25 expression in human peripheral blood mononuclear cells." Journal of Neuroimmunology **119**(2): 333.

<http://www.sciencedirect.com/science/article/B6T03-442XPR6-R/2/32a66410440e29c426f84df9f0015f0e>

Calcium is an important contributor to T cell activation; it is also the major factor in the activation of the calcium-activated neutral proteinase, calpain. For this reason, we wanted to investigate if calpain has a role in T cell activation and what aspects of this activation calpain affects. As measured by semi-quantitative reverse transcriptase-polymerase chain reaction (RT-PCR), calpain inhibition decreased interleukin-2 (IL-2) and CD25 mRNA expression in a dose-dependent manner, at early time points following the initial activation, and over extended periods of time in activated human peripheral blood mononuclear cells (PBMCs). Using an enzyme-linked immuno-sorbent assay (ELISA) specific for human IL-2, we found that calpain inhibition decreased IL-2 secretion in a dose-dependent manner, shortly after activation, and continuously over time. Inhibiting calpain caused a dose-dependent inhibition of CD25 cell surface expression and also inhibited expression shortly after activation and for at least 48 h. This study showed that calpain has an integral role in the synthesis of the two important T cell activation factors, IL-2 and CD25.

Schwarz, H., P. M. Villiger, et al. (1994). "Neuropeptide Y is an inducible gene in the human immune system." Journal of Neuroimmunology **51**(1): 53.

<http://www.sciencedirect.com/science/article/B6T03-476HJ7V-12/2/4c93ee2395ce3483427fcc6e784c3be8>

This study reports on neuropeptide Y (NPY) mRNA expression in human peripheral blood mononuclear cells (PBMC) and lymphoid tissues. By reverse transcription polymerase chain reaction (RT-PCR) it is shown that activated human PBMC of normal blood donors expressed the NPY gene. The PCR products had the expected size and Northern blotting demonstrated the presence of the 0.8-kb NPY mRNA. To define the subpopulations of mononuclear cells expressing this neuropeptide, purified monocytes, B cells and T cells were stimulated with specific activators. Monocytes and in vitro matured macrophages expressed 3PY mRNA in response to phorbol myristate acetate (PMA). B lymphocytes expressed NPY mRNA following stimulation with antibody to surface immunoglobulin and PMA. In order to analyze whether these cell types express NPY under physiological conditions in vivo, human bone marrow, tonsil and thymus were analyzed. In situ hybridization of bone marrow revealed a small number of cells containing high levels of NPY mRNA which was also detected in RNA extracts of human thymus and tonsil. In summary, NPY is an inducible gene in human lymphocytes and monocytes and it is expressed at sites where these cells are activated in vivo.

Sciacca, F. L., C. Ferri, et al. (2000). "Association study of a new polymorphism in the PECAM-1 gene in multiple sclerosis." Journal of Neuroimmunology **104**(2): 174.

<http://www.sciencedirect.com/science/article/B6T03-3YS33NS-B/2/0e7bb4c477810d5342fd1251f9f3aa10>

Genetic polymorphisms of immunorelevant genes may modulate occurrence or clinical features of multifactorial diseases. PECAM-1 is an adhesion molecule crucial for transmigration of cells from blood to tissues, but its genetic contribution to multifactorial diseases has never been investigated. We have identified and characterized a tetranucleotide repeat polymorphism within the third intron of PECAM-1. In a cohort of healthy controls (HC), we found 10 alleles. An assessment of the association of this polymorphism with multiple sclerosis (MS) showed similar allele and genotype frequencies in HC and MS patients as well as in MS patients differing for the gravity of their disease course. We conclude that although potentially able to affect organ-specific autoimmune diseases, this new PECAM-1 polymorphism, does not seem to contribute to the genetic background of MS.

Sedqi, M., S. Roy, et al. (1996). "Expression cloning of a full-length cDNA encoding delta opioid receptor from mouse thymocytes." Journal of Neuroimmunology **65**(2): 167.

<http://www.sciencedirect.com/science/article/B6T03-3W496PR-B/2/bd214dd7346ef81c9cd6e57fbff89d3c>

A delta opioid receptor complementary DNA (cDNA) was cloned by expression of cDNA library from activated thymocytes in Cos 7 cells. The deduced amino acid sequence of this receptor was similar to that described in the brain. As analyzed by southern blot hybridization, the delta opioid receptor transcripts are constitutively expressed in unactivated thymocytes. In addition, neither [kappa] nor [mu] opioid receptor transcripts were detected in thymocytes, suggesting tissue-specific opioid receptor gene expression in the immune system. The studies represent the first report of a full-length opioid receptor in the immune system.

Selmaj, K., C. Kowal, et al. (2000). "Naked DNA vaccination differentially modulates autoimmune responses in experimental autoimmune encephalomyelitis." Journal of Neuroimmunology **111**(1-2): 34.

<http://www.sciencedirect.com/science/article/B6T03-41J66JG-5/2/c2d1bce2466dedd2629dc569c1cbaf96>

Vaccination with naked DNA represents a therapeutic strategy currently under consideration in multiple sclerosis (MS). In this study, we tested the potential therapeutic effect of vaccination with a naked DNA construct encoding proteolipid protein (pRc/CMV-PLP) upon the outcome of subsequent sensitization for experimental autoimmune encephalomyelitis (EAE) actively-induced in SJL mice with PLP139-151 peptide in adjuvant. Intramuscular vaccination with the naked DNA pRc/CMV-PLP construct led to PLP expression in local muscle tissue that persisted for about 8 weeks. Early sensitization for EAE (4 weeks after DNA vaccination) caused recipient mice to develop a severe, exacerbated form of disease (in comparison to control mice), while late sensitization (>10 weeks) resulted in a milder, ameliorated form. In the groups sensitized 10 weeks post-DNA vaccination led to peripheral tolerance as evidenced by a decrease in T cell proliferation and cytotoxic T cell response, no Th2 response, and no increase in apoptosis. These data are novel in that they demonstrate a differential effect of DNA vaccination and have important implications for its use as a mechanism to enhance or modulate immune reactivity.

Shahabi, N. A., Y. Daaka, et al. (1999). "Delta opioid receptors expressed by stably transfected jurkat cells signal through the map kinase pathway in a ras-independent manner." Journal of Neuroimmunology **94**(1-2): 48.

<http://www.sciencedirect.com/science/article/B6T03-3VNPV73-5/2/661a1db953b9c8a9bbdf0073e3480e3e>

Delta opioid receptors (DOR) are G-protein coupled 7-transmembrane receptors (GPCR), expressed by thymic and splenic T cells, that modulate interleukin (IL)-2 production and proliferation in response to concanavalin A or crosslinking the TCR. Mitogen-activated protein kinases (MAPKs) are involved in mediating intracellular responses to TCR crosslinking. In addition, MAPKs can be activated by signaling cascades that are initiated by the release of G-proteins from GPCRs. To determine whether DORs expressed by T cells signal through the MAPKs, extracellular-regulated kinases (ERKs) 1 and 2, two delta opioid peptides, deltorphin and [-Ala2,-Leu5]-enkephalin (DADLE), were studied in Jurkat cells that had been stably transfected with DOR (DOR-Ju.1). These peptides rapidly and dose-dependently induced ERK phosphorylation; pretreatment with naltrindole (NTI), a selective DOR antagonist, abolished this. Pertussis toxin (PTX) also inhibited phosphorylation, indicating the involvement of the Gi/o proteins. Herbimycin A, a protein tyrosine kinase (PTK) inhibitor, reduced the DADLE-induced ERK phosphorylation by 68%. ERK phosphorylation was inhibited by Bisindolylmaleimide 1 (GF109203X), an inhibitor of PKC, and by pretreatment with PMA prior to DADLE. A GTP/GDP exchange assay was used to assess the potential role of Ras in the pathway leading to ERK phosphorylation; DADLE failed to stimulate GTP/GDP exchange in comparison to PMA. Additional studies showed that DADLE stimulated an increase in cfos mRNA; this was reduced by the inhibitor of MAPK/ERK kinase (MEK), PD98059. Therefore, in DOR-Ju.1 cells, DOR agonists stimulate ERK phosphorylation in a Ras independent and PKC-dependent manner; PTKs appear to be involved. MAPKs mediate the increase in cfos mRNA induced by DOR agonists.

Sharp, B. M., N. Shahabi, et al. (1997). "Detection of basal levels and induction of delta opioid receptor mRNA in murine splenocytes." Journal of Neuroimmunology **78**(1-2): 198.

<http://www.sciencedirect.com/science/article/B6T03-3R7J7TN-T/2/30b2caf1bc1a471b250fc774b93494c6>

Activation of delta opioid receptors (DOR) modulates calcium mobilization, interleukin-2 production, chemotaxis and proliferation of T-lymphocytes. Recent reports indicate that lymphocytes and mononuclear cells may express mRNA transcripts for DOR. The investigations reported herein show that low levels of DOR were consistently detected by RT-PCR amplification of RNA from freshly obtained Balb/c murine splenocytes, both weanling and adult. Culturing cells without stimulation increased DOR levels and concanavalin A apparently reduced this; DOR was preferentially expressed in a T-cell-enriched fraction. Thus, the expression of DOR mRNA by unactivated splenocytes is modulated by culture and con A in the T-cell fraction.

Shrikant, P., C. Il Yup, et al. (1994). "Regulation of intercellular adhesion molecule-1 gene expression by tumor necrosis factor-[alpha], interleukin-1[beta], and interferon-[gamma] in astrocytes." Journal of Neuroimmunology **51**(2): 209.

<http://www.sciencedirect.com/science/article/B6T03-476WCJ3-X/7/2/10c3570a28de34dab7faadb50d3e5e68>

Intercellular adhesion molecule-1 (ICAM-1) is a cell surface glycoprotein which can be induced on astrocytes, the major glial cell of the central nervous system (CNS). In this study, we examined the effect of three proinflammatory cytokines, tumor necrosis factor-alpha (TNF-[alpha]), interleukin-1 beta (IL-1[beta]), and interferon-gamma (IFN-[gamma]), on the expression of ICAM-1 by primary rat astrocytes. Astrocytes constitutively express ICAM-1 mRNA and protein, which is enhanced by treatment with TNF-[alpha], IL-1[beta] and IFN-[gamma]. TNF-[alpha] is the most potent inducer of ICAM-1 expression, followed by IL-1[beta], then IFN-[gamma]. Kinetic analysis demonstrated optimum ICAM-1 mRNA expression after a 1-h exposure to TNF-[alpha], 2 h exposure to IL-1[beta], and 4 h exposure to IFN-[gamma]. Peak ICAM-1 protein expression was detected 12-16 h after treatment with TNF-[alpha] or IL-1[beta], and after a 24-h exposure to IFN-[gamma]. Nuclear run-on analysis demonstrated that the ICAM-1 gene is transcribed under basal conditions in astrocytes, and that both TNF-[alpha] and IL-1[beta] enhance transcriptional activation of the ICAM-1 gene. ICAM-1 mRNA stability studies determined that basal ICAM-1 mRNA has a half-life of about 1 h, and that TNF-[alpha], IL-1[beta] and IFN-[gamma] have a modest effect on stabilization of basal ICAM-1 mRNA expression. These results indicate that under inflammatory conditions in the CNS, such as multiple sclerosis (MS) and experimental allergic encephalomyelitis (EAE), astrocytes can be induced to express the adhesion molecule ICAM-1, which can contribute to inflammatory events within the CNS.

Sierra-Honigsmann, A. M., S. A. Rubin, et al. (1993). "Borna disease virus in peripheral blood mononuclear and bone marrow cells of neonatally and chronically infected rats." Journal of Neuroimmunology **45**(1-2): 31.

<http://www.sciencedirect.com/science/article/B6T03-476WCFH-W1/2/a38e1296003ebdc5af5e57da7ccb38ff>

Borna disease virus (BDV) establishes a persistent infection in cells of the nervous system in rats. The response, or lack thereof, of the immune system to BDV infection of neurons is responsible for the presence or absence, respectively, of Borna disease. We recently demonstrated

transmission of BDV by bone marrow cells from neonatally infected rats. Our findings suggested the possibility of a heretofore unsuspected interaction between BDV and the immune system, that of direct effects of BDV infection on the cells of the immune system. This report enlarges upon the previous findings and confirms the presence of BDV RNA in bone marrow cells of neonatally infected rats, using a reverse transcription-polymerization chain reaction-enzyme immunosorbent assay (RT-PCR-EIA). In addition, we detected BDV RNA in peripheral blood mononuclear cells of neonatally infected rats, and in rats inoculated as adults in the chronic, but not the acute, stage of infection. In addition, the RT-PCR-EIA technique identified BDV RNA in cerebrospinal fluid, nasal secretions, saliva, urine and stool. BDV-sequences were not detected in the plasma of infected animals nor in the body fluids and tissues of normal rats.

Skorupa, A. F., S. C. G. Brezinski, et al. (2001). "Expression of Golli mRNA during development in primary immune lymphoid organs of the rat." Journal of Neuroimmunology **119**(1): 64.

<http://www.sciencedirect.com/science/article/B6T03-43T7TV1-8/2/1e290e509c09a562efdfb4492b89a213>

The gene-of-the-oligodendrocyte lineage (Golli)-MBP transcription unit contains three Golli-specific exons together with eight exons of the "classical" myelin basic protein (MBP) gene, yielding alternatively spliced proteins which share amino acid sequence with MBP. Unlike MBP, a late antigen expressed only in the nervous system, Golli gene products are expressed pre- and post-natally at many sites. In this study, we determined the sequence of Golli in rat by RT-PCR and 5' RACE and showed that Golli sequences are expressed in primary lymphoid organs as early as e16.5, which could explain the anergic rat T cell response we previously observed in Golli-induced meningitis.

Stinissen, P., J. Zhang, et al. (1998). "[gamma][delta] T cell responses to activated T cells in multiple sclerosis patients induced by T cell vaccination." Journal of Neuroimmunology **87**(1-2): 94.

<http://www.sciencedirect.com/science/article/B6T03-3TCFKBS-D/2/7d104c3ce2ce497a7136eaa09c53491d>

To explore the hypothesis that [gamma][delta] T cells may regulate activated [alpha][beta] T cells, we studied [gamma][delta] T cell responses to [alpha][beta] T cell clones in Multiple Sclerosis (MS) patients who received attenuated autologous autoreactive T cells. We recently conducted a pilot study of T cell vaccination with myelin basic protein reactive T cells in MS. Since T cell vaccination upregulates the anti-vaccine T cell responses, we evaluated [gamma][delta] T cell reactivity towards the vaccine in the vaccinated patients. Lymphocytes were stimulated in vitro with irradiated vaccine cells and the responding lines were checked for the presence of [gamma][delta] T cells. Our data demonstrate that in the majority of vaccinated MS patients [gamma][delta] T cells expand upon stimulation with the vaccine cells. The responding [gamma][delta] T cells were predominantly V[delta]1+/V[gamma]1+, and represented diverse clonal origins. The [gamma][delta] T cells could not inhibit in vitro proliferation of the vaccine T cells and displayed low cytotoxic reactivity towards the vaccine clones. However, they produced high levels of IL2, TNF[alpha] and IL10. These results indicate that [gamma][delta] T cells can be stimulated by activated [alpha][beta] T cells, and that these [gamma][delta] T cell responses are upregulated after T cell vaccination. These findings suggest that [gamma][delta] T cells are involved in peripheral mechanisms to control activated autoreactive T cells.

Storto, M., U. de Grazia, et al. (2000). "Expression of metabotropic glutamate receptors in murine thymocytes and thymic stromal cells." Journal of Neuroimmunology **109**(2): 112.

<http://www.sciencedirect.com/science/article/B6T03-416BXKJ-8/2/77eb587eee3257eb4dd9fa07a1292290>

RT-PCR combined with immunoblotting showed the expression of group-I (mGlu1 and 5) and group-II (mGlu2 and 3) metabotropic glutamate receptors in whole mouse thymus, isolated thymocytes and TC-1S thymic stromal cell line. Cytofluorimetric analysis showed that mGlu-5 receptors were absent in CD4-/CD8- but present in more mature CD4+ CD8+ and CD4+CD8- thymocytes. mGlu-1a receptors showed an opposite pattern of expression with respect to mGlu5, whereas mGlu2/3 receptor expression did not differ between double negative and double positive cells. mGlu receptors expressed in both thymic cell components were functional, as indicated by measurements of polyphosphoinositide hydrolysis or cAMP formation. These data suggest a possible role for mGlu receptor signalling in the thymus.

Szczepanik, A. M., S. Funes, et al. (2001). "IL-4, IL-10 and IL-13 modulate A[beta](1-42)-induced cytokine and chemokine production in primary murine microglia and a human monocyte cell line." Journal of Neuroimmunology **113**(1): 49.

<http://www.sciencedirect.com/science/article/B6T03-41Y28FP-6/2/53671e21c5a94a9775f9364e7a06b2fe>

A hallmark of the immunopathology associated with Alzheimer's disease (AD) is the presence of activated microglia surrounding senile plaque deposits of [beta]-amyloid (A[beta]) peptides. A[beta] peptides have been shown to be potent activators of microglia and macrophages, but little is known about endogenous factors that may modulate their responses to amyloid. We investigated whether the 'anti-inflammatory' cytokines IL-4, IL-10 and IL-13 could regulate A[beta]-induced production of the inflammatory cytokines IL-1[alpha], IL-1[beta], TNF-[alpha], IL-6 and the chemokine MCP-1. A[beta](1-42) time- and dose-dependently induced the production and secretion of these inflammatory proteins in the human THP-1 monocyte cell line and in primary murine microglia, similar to what was observed for lipopolysaccharide (LPS) stimulated cells. IL-10 was found to suppress all A[beta] and LPS-induced inflammatory proteins measured (IL-1[alpha], IL-1[beta], IL-6, TNF-[alpha] and MCP-1) in both cell types with the exception of LPS-induced MCP-1 in THP-1 cells where no change was observed. In contrast to the inhibition observed for IL-10, both IL-4 and IL-13 enhanced MCP-1 secretion. IL-4 and IL-13 reduced IL-6 secretion, but effects on IL-1[alpha], IL-1[beta] or TNF-[alpha] were dependent on cell type and stimulus conditions. Additional experiments using RT-PCR showed that IL-4, IL-10 and IL-13 mRNA is found to be present in human brain tissue. These results show that IL-4, IL-10, and IL-13 differentially regulate microglial responses to A[beta] and may play a role in the inflammation pathology observed surrounding senile plaques.

van der Meulen, M. F. G., D. F. van Wichen, et al. (2002). "Evidence for heterogeneity of T cell expansion in polymyositis and inclusion body myositis." Journal of Neuroimmunology **133**(1-2): 198.

<http://www.sciencedirect.com/science/article/B6T03-473MDJN-8/2/62fb9bfc2d78098e014bddcf8d4a5a7f>

V[beta] usage of muscle-infiltrating T lymphocytes in polymyositis (PM) and sporadic inclusion body myositis (s-IBM) was correlated with clinical and histopathological features. Immunohistochemical analysis was combined with complementarity-determining region 3 (CDR3)

length analysis in nine muscle biopsies of eight PM patients and six biopsies of five s-IBM patients. V[beta] usage was heterogeneous in seven patients. Four of these patients had definite PM with endomysial located T cell infiltrates, but T cells specifically surrounding and invading individual non-necrotic fibers were not found. In two s-IBM patients, V[beta] 2 usage was increased. In one of them, a repeat biopsy showed a heterogeneous V[beta] usage. We conclude that clonal expansion of muscle-infiltrating T cells could only be detected in part of the patients. Explanations may be that clonal expansion does not take place in all disease phases and that PM is a heterogeneous disease with respect to pathogenesis.

van Sorge, N. M., W. L. van der Pol, et al. "Severity of Guillain-Barre syndrome is associated with Fc[gamma] Receptor III polymorphisms." *Journal of Neuroimmunology* **In Press, Corrected Proof** <http://www.sciencedirect.com/science/article/B6T03-4FNDRX7-1/2/3be0aafac7e642d89d6a15eb0ea3822a>

Macrophages and ganglioside-specific IgG are involved in the pathogenesis of Guillain-Barre syndrome (GBS). Leukocyte IgG receptors (Fc[gamma]R) confer potent cellular effector functions to the specificity of IgG. The efficacy of IgG-mediated cellular inflammatory responses is determined by functional polymorphisms of three Fc[gamma]R subclasses (Fc[gamma]RIIa: H131/R131; Fc[gamma]RIIIa: V158/F158; Fc[gamma]RIIIb: NA1/NA2). Fc[gamma]R genotype distributions were determined in a Dutch, and British cohort of GBS patients and controls. In addition, a meta-analysis incorporating all previously published data, encompassing a total of 345 GBS patients and 714 healthy controls, was performed. Results suggest that Fc[gamma]RIII genotypes may represent mild disease-modifying factors in GBS.

Vandenbroeck, K., G. Martino, et al. (1997). "Occurrence and clinical relevance of an interleukin-4 gene polymorphism in patients with multiple sclerosis." *Journal of Neuroimmunology* **76**(1-2): 189.

<http://www.sciencedirect.com/science/article/B6T03-3PSB1XD-V/2/9689c82c112f673f33b3397b3975017e>

An epistatic gene interaction has been advocated to explain disease susceptibility in multiple sclerosis (MS). Cytokine genes are possible candidates due to the central role played by cytokines in the regulation of the immune-mediated pathogenetic process leading to central nervous system demyelination in these patients. Since interleukin (IL)-4 gene polymorphisms have been associated with immune-mediated diseases, we have analysed the relationship between a variable number of tandem repeat polymorphism of the IL-4 gene and clinical and physiological features of 256 sporadic MS patients and 146 healthy controls. Genotype frequencies were similar between the MS group and healthy controls. However, in MS patients a positive and significant correlation ($r=0.91$; $p<0.001$) was found between the carriage rate of the IL-4 B1 allele (from 0.21 to 0.36) and age of disease onset. No association was found between IL-4 alleles and disease progression, sex or ethnic background of the patients. Our results show that the IL-4 B1 allele is associated with late onset of MS and therefore might represent a modifier of age of onset rather than a susceptibility factor for patients with MS.

Yamabe, T., G. Dhir, et al. (1994). "Cytokine-gene expression in measles-infected adult human glial cells." *Journal of Neuroimmunology* **49**(1-2): 171.

<http://www.sciencedirect.com/science/article/B6T03-476HK1W-7D/2/bb5d439bf483a77e9c61e55e06575557>

The expression of interleukin (IL)-1[beta], IL-6 and tumor necrosis factor (TNF) [alpha] transcripts in cultured human glial cells was examined using reverse transcription followed by polymerase chain reaction (PCR) amplification and Southern blot quantitation. Microglial cultures derived from brain biopsy specimens from three different individuals expressed transcripts for the three cytokines under basal culture conditions. This expression was enhanced in response to measles virus (MV) infection (IL-1[beta], 2.2-8.8-fold; IL-6, 2.5-8.4-fold; TNF[alpha], 2.2-3.2-fold). Neither IL-1[beta] nor TNF[alpha] transcripts were detectable in undissociated brain tissue from two individuals, suggesting that the basal expression of these cytokines in culture may have been induced by tissue dissociation or by the culture conditions. Oligodendrocytes did not express cytokine transcripts under basal culture conditions, and IL-1[beta] and IL-6 but not TNF[alpha] transcripts could be induced by MV. Similarly, meningeal fibroblasts expressed IL-1[beta] and IL-6 but not TNF[alpha] in response to MV-infection, suggesting that the production of TNF[alpha] is more cell type-restricted than either IL-1[beta] or IL-6. The results indicate that adult human microglia can participate in the inflammatory response to MV infection in the CNS by producing cytokines that contribute to inflammation and demyelination. In addition, besides their role in myelination, oligodendrocytes can potentially influence immunoreactivity in the CNS by producing IL-1[beta] and IL-6.

Yamakuni, H., N. Kawaguchi, et al. (2002). "ATP induces leukemia inhibitory factor mRNA in cultured rat astrocytes." *Journal of Neuroimmunology* **129**(1-2): 43.

<http://www.sciencedirect.com/science/article/B6T03-468VMH4-2/2/8c2a1e213354cd968c18c909df8a7b36>

Leukemia inhibitory factor (LIF) is a cytokine involved in the survival and differentiation of the neural cells in the central and peripheral nervous systems. In the present study, we examined the effects of various neurotransmitter receptor agonists on LIF mRNA expression in cultured rat astrocytes, microglia and neurons to elucidate the cell types producing LIF and to clarify the neurotransmitter(s) regulating the mRNA expression. The results demonstrated that the expression of LIF mRNA was intensely induced by ATP in the cultured astrocytes. Experiments using ATP, UTP and related compounds showed the involvement of P2Y2 and P2Y4 purinoceptors in the expression induced by ATP.

Ye, S.-M. and R. W. Johnson (2001). "Regulation of interleukin-6 gene expression in brain of aged mice by nuclear factor [kappa]B." *Journal of Neuroimmunology* **117**(1-2): 87.

<http://www.sciencedirect.com/science/article/B6T03-43B8BRH-B/2/90a66f194977ab7f9d558cd84f4e66f8>

Interleukin-6 (IL-6) is increased in brain of aged mice. The purpose of this study was to determine if binding of nuclear factor [kappa]B (NF[kappa]B) to the IL-6 promoter is responsible for the age-related increase in brain IL-6. In an initial study, the effect of age on IL-6 in brain was verified as IL-6 protein was increased in brain of aged mice compared to adult and juvenile mice. Competitive RT-PCR showed that IL-6 mRNA concentration was at least 4-fold higher in aged brain compared to adult brain. Next, binding of the transcription factor NF[kappa]B to the IL-6 promoter in brains of 1-, 6-, and 24-month-old mice was determined. Electrophoretic mobility shift assay showed that NF[kappa]B activity was increased in aged brain compared to adult and juvenile brain. Moreover, glial cells cultured from aged mice showed more NF[kappa]B DNA-binding activity and more IL-6 mRNA and protein expression than glia from adults. However, incubating glia from aged mice in the presence of [kappa]B decoy inhibited these effects of age. The same was observed in vivo as intracerebroventricular injection of [kappa]B decoy in aged mice decreased NF[kappa]B activity and IL-6 mRNA and protein in brain. These results show that

the DNA-binding activity of NF[κ]B is increased in the brain of aged mice and that at least one consequence is increased expression of IL-6.

Zwijnenburg, P. J. G., T. van der Poll, et al. (2003). "Interleukin-18 gene-deficient mice show enhanced defense and reduced inflammation during pneumococcal meningitis." Journal of Neuroimmunology **138**(1-2): 31.

<http://www.sciencedirect.com/science/article/B6T03-487KRJ5-1/2/0f8e8c8a2389462364c7bb736263d52f>

To determine the role of endogenous interleukin-18 (IL-18) in pneumococcal meningitis, meningitis was induced in IL-18 gene-deficient (IL-18^{-/-}) and wild-type (WT) mice by intranasal inoculation of *Streptococcus pneumoniae* with hyaluronidase. Induction of meningitis resulted in an upregulation of both pro- and mature IL-18 in brain tissue in WT mice. IL-18^{-/-} and WT mice were equally susceptible to develop meningitis after intranasal infection, yet IL-18^{-/-} mice showed a prolonged survival and a suppressed inflammatory response, as reflected by a less profound inflammatory infiltrate around the meninges and lower concentrations of cytokines and chemokines in brain tissue. These findings suggest that endogenous IL-18 contributes to a detrimental inflammatory response during pneumococcal meningitis and that elimination of IL-18 may improve the outcome of this disease.

Castro, R. M. R. P. S., M. C. Landemberger, et al. (2004). "High capacity and low cost detection of prion protein gene variant alleles by denaturing HPLC." Journal of Neuroscience Methods **139**(2): 263.

<http://www.sciencedirect.com/science/article/B6T04-4CP17PJ-2/2/145d98e2cbee1b579fbbad6cd7b3e1cf>

Mutations in the human prion protein gene (PRNP) are responsible for hereditary diseases called transmissible spongiform encephalopathies (TSE) and a polymorphic site at codon 129 determines sensitivity to infectious forms of these maladies. More recently, codon 129 has been related to cognition performance in the elderly, in Alzheimer disease (AD) and in Down syndrome. Furthermore, a rare polymorphism at codon 171 was described in 23% of patients with mesial temporal lobe epilepsy related to hippocampal sclerosis (MTLE-HS), the most common form of surgically remediable epileptic syndrome. Thus, a method that permits fast and efficient screening of PRNP mutations and polymorphisms in patients, in high risk populations, and in family members is desirable. In the present study, we established the conditions for analysis of the PRNP open reading frame using denaturing high-performance liquid chromatography (DHPLC), whereby unpurified PCR products were subjected to denaturing and reannealing steps leading to heteroduplex formation. We described specific profiles for the PRNP polymorphisms at codons 129 (M/V), 117 (A/A silent), 219 (E/K), 171 (N/S), and the octarepeat deletion using amplified DNA from 562 samples. The chromatograms for TSE-associated mutations at codons 102 (P/L), 183 (T/A), and 210 (V/I) were also determined. Specificity of the DHPLC profile for each PRNP variant allele was confirmed in 100% of the samples by direct and cloned DNA sequencing in addition to endonuclease digestion when applicable. Therefore, the present study shows that DHPLC is a rapid, highly accurate and efficient technique for the detection of PRNP genetic

variants.

Dilks, D. W., R. H. Ring, et al. (2003). "High-throughput confirmation of differential display PCR results using reverse Northern blotting." Journal of Neuroscience Methods **123**(1): 47.

<http://www.sciencedirect.com/science/article/B6T04-47RBBV9-4/2/54f9e0c8cc624e10309406ac6d9d3ffa>

Nylon filter arrays spotted with differential display PCR (DD-PCR) clones and hybridized with radiolabeled cRNA generated from the source RNA pool (reverse Northern blot) provide a high-throughput means to screen clones for artifacts. Reverse Northern blots also confirm differential gene expression in parallel and require modest quantities of the source RNA pool. We describe a strategy to screen multiple candidates from DD-PCR by high-throughput ligation and transformation, followed by reverse Northern blotting. Purification of re-amplified DD-PCR clones and fabrication of nylon arrays was facilitated by a batch-processing protocol using the widely available Biomek(R) laboratory robot and Bioworks(TM) scripts (available from the authors). A strategy to screen out DD-PCR product artifacts of an inappropriate size was also employed. Using these approaches, we identified several mRNAs that are differentially expressed in response to venlafaxine, fluoxetine or desipramine antidepressant treatment in rat C6 glioma cell lines and are candidates for full length clone isolation using 5'-RACE. Such an approach provides a rapid means to eliminate the high percentage of false positive clones from DD-PCR and enables independent confirmation of differential gene expression patterns generated by various experimental conditions.

Gioia, L., L. J. Vogt, et al. (1998). "PCR-based apolipoprotein E genotype analysis from archival fixed brain." Journal of Neuroscience Methods **80**(2): 209.

<http://www.sciencedirect.com/science/article/B6T04-3SVS087-C/2/f32dd60265dec99686d7204d8e0eb2f5>

A technique is described for determining the apolipoprotein E genotype (apo E; alleles [epsilon]2, [epsilon]3, or [epsilon]4) from tissues which have been fixed with 4-10% formaldehyde and archived. The procedure requires efficient extraction and exhaustive purification of DNA from the fixed tissue. Because the fixation process renders the DNA largely crosslinked and/or sheared (therefore unsuitable for traditional analysis), a nested polymerase chain reaction (PCR) is employed (using two apo E gene specific primer pairs) to specifically amplify the polymorphic region of the gene. The genotype was then determined using previously reported HhaI polymorphisms that occur as a direct result of the variant codons responsible for the three alleles. This protocol permitted the successful genotyping of 90% (34 out of 38) of the archived brain samples from Alzheimer's disease (AD) patients. These samples included such extremes as a sample that had been stored for 12 years in formalin. This procedure permits the retrospective analysis of samples that had been processed and stored well before the original characterization of apo E alleles as risk factors in AD. Finally, this approach is readily adapted to the analysis of any gene of interest, whether by restriction fragment length polymorphism or direct amplicon DNA sequencing. It is also a very robust assay for less stringent conditions such as DNA isolated from whole blood or frozen tissue.

Gutala, R. V. and P. H. Reddy (2004). "The use of real-time PCR analysis in a gene expression study of Alzheimer's disease post-mortem brains." Journal of Neuroscience Methods **132**(1): 101.

<http://www.sciencedirect.com/science/article/B6T04-4B42D2D-1/2/9b30501d8a2efcd11974171fbb66596f>

The measurement of gene expressions in brains with neurodegenerative diseases is a major area of brain research. The objective of our research was to determine whether quantitative real-time PCR could measure messenger RNA (mRNA) expression in brains with post-mortem intervals beyond 12 h. In the present paper, we examined the quality of RNA from brain specimens of both Alzheimer's disease (AD) patients (n=13) and non-demented normal control subjects (n=6). To determine an unregulated endogenous reference gene in AD, we measured mRNA expressions of the commonly used reference genes [beta]-actin, 18S rRNA, and GAPDH. In addition, we determined whether post-mortem interval, brain weight, or age at death influences mRNA expression. Our real-time PCR analysis results indicate that mRNA expression can be detected in all brain specimens for [beta]-actin, 18S rRNA, GAPDH, and also synaptophysin, a known marker for AD. Further, using real-time PCR analysis, we found that [beta]-actin and 18S rRNA are differentially expressed in the brain specimens of both AD and control subjects, while GAPDH is similarly expressed in AD and control brain specimens. These findings suggest that GAPDH can be used as an endogenous reference gene in the study of AD brains. A comparative gene expression analysis also suggests that synaptophysin is down-regulated in AD brain specimens compared to control brain specimens.

Lambert, J.-F., B. O. Benoit, et al. (2000). "Quick sex determination of mouse fetuses." Journal of Neuroscience Methods **95**(2): 127.

<http://www.sciencedirect.com/science/article/B6T04-3YJ9XNG-5/2/e8b8b4e03b0ffe1953a5ff20ad1450c3>

We designed a rapid, simple and accurate PCR method to determine sexual identity of mouse fetuses collected on embryonic day 15. A multiplex PCR amplification was used to detect male-specific sequence (Sry) in DNA extracted from fetal livers through SDS denaturation followed by high salt extraction and precipitation. This extraction method resulted in sufficiently purified DNA in <1 h and was suitable for PCR. The DNA obtained was amplified using a robot thermal cycler for 33 cycles. The reaction was performed in 50 [mu]l, using two sets of primers specific for Sry gene (chromosome Y) and IL3 gene (chromosome 11). Amplification duration was 1.5 h. The assessment of the results was done by electrophoresis in 3% agarose run at high voltage. The 402 bp band (Sry) obtained identifies the male fetuses and the 544 bp product (IL3) confirms the correct amplification of the template DNA. The entire procedure took <4 h. The specificity of the method was confirmed by fluorescent in situ hybridization using a specific male probe on cultured male and female neural stem cells. This method allowed the preparation and culture of pure male and female neural stem cells from fetal tissue.

Personett, D. A., M. Chouinard, et al. (1996). "Simplified RT/PCR quantitation of gene transcripts in cultured neuroblastoma (SN49) and microglial (BV-2) cells using capillary electrophoresis and laser-induced fluorescence." Journal of Neuroscience Methods **65**(1): 77.

<http://www.sciencedirect.com/science/article/B6T04-3VWPC7R-B/2/c39ab86ce993a3e02f31861567dc2d3d>

We developed a simplified protocol for sensitive quantitation of mRNA using polymerase chain reaction (PCR) amplification of cDNA made by reverse transcriptase (RT), as resolved with capillary electrophoresis (CE) and detected with laser-induced fluorescence (LIF). The conditions required for adequate accuracy of the simplified version of the RT/PCR quantitation, in which a

single concentration of external standard and amplification to within or near the plateau phase are used, were established for assay of mRNAs expressed at high, moderate, and low abundance. The mRNAs for the cytosolic enzyme, glyceraldehyde phosphate dehydrogenase (GAPDH) and the growth-associated protein GAP-43 in cultured SN49 neuroblastoma cells were used as target genes for high and moderate levels of expression, respectively. Using cultured mouse microglial cells (BV-2), we demonstrated the utility of this RT/PCR/CE/LIF protocol to quantitate a low-abundance mRNA, encoding a form of nitric oxide synthase (i-NOS) induced by treatment with endotoxin. The appearance of i-NOS mRNA after endotoxin treatment of BV-2 cells was confirmed by Northern blot analysis and in situ hybridization histochemistry, and functional enzyme activity was followed by release of nitric oxide (as nitrite) into the medium. The many advantages of the 'single-point' RT/PCR/CE/LIF protocol for quantitating mRNAs of interest include: simplified protocol, elimination of the use of radiotracers, high sensitivity and precision, and semi-automation of the quantitation phase of analysis.

Petraroli, R., G. Vaccari, et al. (2000). "A rapid and efficient method for the detection of point mutations of the human prion protein gene (PRNP) by direct sequencing." Journal of Neuroscience Methods **99**(1-2): 59.

<http://www.sciencedirect.com/science/article/B6T04-40X8CH9-7/2/3a5e383759be3eb3b01aa19745f9e76e>

Creutzfeldt-Jakob disease (CJD) and related disorders occur in sporadic, acquired and inherited forms. In sporadic, iatrogenic and new variant CJD the polymorphic codon 129 of the prion protein gene (PRNP) plays an important role for the susceptibility to the disease and for the clinical and neuropathological manifestations. All the inherited forms of CJD and related disorders are linked to point or insert mutations of PRNP. The analysis of PRNP is therefore important for a correct classification of these disorders and for the identification of novel mutations. The aim of the present study is to describe a fast and easy to perform method for the direct sequencing of the PCR amplified PRNP open reading frame, by using M13 tailed primers which allow a direct and rapid method of sequencing. The goodness of this method is demonstrated in the analysis of three sporadic CJD patients with different genotypes at codon 129 and three inherited cases bearing different point mutations of PRNP: the Pro102Leu mutation linked to Gerstmann-Straussler-Scheinker-syndrome, the Val210Ile mutation and a novel mutation at codon 211 (Gln211Glu) both associated to familial CJD.

Schimmelpfeng, J., K. F. Weibezahn, et al. (2004). "Quantification of NGF-dependent neuronal differentiation of PC-12 cells by means of neurofilament-L mRNA expression and neuronal outgrowth." Journal of Neuroscience Methods **139**(2): 299.

<http://www.sciencedirect.com/science/article/B6T04-4CS4RY0-1/2/01cd180a71535f64846e7c8af377ad8b>

We demonstrate that the degree of neuronal development of PC-12 cell differentiation can be quantified by the expression of neurofilament-L (NF-L) mRNA, when an optimal concentration of NGF (50 ng/ml) is used. During the first 7 days of NGF treatment, the relative amount of NF-L mRNA was found to increase continuously and to correlate with the outgrowth of neurites in a statistically significant way. Thus, mRNA expression is, under these conditions, a suitable means for reliably monitoring the differentiation of PC-12 cells as early as after 3 days of NGF treatment. The results obtained with 5 ng/ml NGF differ from those with 50 ng/ml: during the first 3 days of NGF treatment, neuronal outgrowth was less than with 50 ng/ml, although the NF-L mRNA levels did not depend significantly on NGF concentration. Beyond day 3, NF-L mRNA levels did not increase further at 5 ng/ml as opposed to 50 ng/ml NGF. These differences point to different

signal transduction processes involved in neuronal differentiation at high and low NGF concentration. Expression of NF-L protein in response to NGF treatment was also demonstrated. In summary, our results stress that stable and sustained differentiation of PC-12 cells can only be achieved with 50 ng/ml NGF.

Teupser, D., N. Heino, et al. (2002). "Rapid detection of the prion protein M129V polymorphism with the LightCycler." Journal of Neuroscience Methods **115**(1): 93.

<http://www.sciencedirect.com/science/article/B6T04-450HHKR-1/2/8b559299c7d239e59291a66e1e6b81c4>

The common single nucleotide polymorphism at codon 129 of the prion protein gene is a key determinant of the genetic susceptibility to Creutzfeldt-Jakob disease (CJD). Recently, a molecular classification of sporadic CJD based on the M129V genotype in conjunction with other determinants was proposed. In the present study, we describe the development and evaluation of a rapid fluorescent-based assay to detect this polymorphism using the LightCycler system. The two polymorphic alleles could be clearly distinguished by their melting points at 52.1 and 60.4 [deg]C, representing the 129V and 129M alleles, respectively. These results were confirmed by DNA sequencing. We evaluated our test in 400 patient samples and found no deviations from the expected melting patterns. The calculated allele frequency for the M-allele was 0.66. Thus, we have established a rapid, reliable fluorescent assay for high-throughput detection of the prion protein M129V polymorphism.

Torres, J. M., P. Sanchez, et al. (2004). "Quantitation of mRNA levels of steroid 5[alpha]-reductase isozymes in the rat brain by "one-step" RT-PCR and capillary electrophoresis." Journal of Neuroscience Methods **135**(1-2): 211.

<http://www.sciencedirect.com/science/article/B6T04-4BNMPTG-6/2/6a31b351d53580bdc82cec1e3659e1f4>

The enzyme 5[alpha]-reductase (5[alpha]-R) is present in many mammalian tissues, including the brain. The physiological importance of 5[alpha]-R in the brain derives from its capability to convert testosterone (T) to a more potent androgen, dihydrotestosterone (DHT), and to convert progesterone to its 5[alpha]-reduced derivative, precursors of allopregnanolone, potent allosteric modulator of the [gamma]-aminobutyric acid receptor (GABAA-R). 5[alpha]-R occurs as two isoforms, 5[alpha]-R type 1 (5[alpha]-R1) and 5[alpha]-R type 2 (5[alpha]-R2). We present an accurate, rapid, and modestly labor-intensive method to precisely quantitate 5[alpha]-R mRNA species in the cerebral cortex of the rat. This approach combines the high specificity of "one-step" reverse transcription-polymerase chain reaction (RT-PCR) with the sensitivity of laser-induced fluorescence capillary electrophoresis (LIF-CE). Both cDNA synthesis and PCR amplification are performed with the same enzyme and site-specific primers, improving the efficiency of cDNA synthesis. The specific target mRNA and a mimic DNA fragment, used as a competitive internal standard, were co-amplified in a single reaction in which the same primers are used. The method presented in this paper enables a more efficient quantitative determination of 5[alpha]-R mRNA isozymes, and may lead to a better understanding of the role of 5[alpha]-R isozymes in the physiology of the central nervous system.

Henry, C. H., A. P. Hudson, et al. (1999). "Identification of Chlamydia trachomatis in the human temporomandibular joint." Journal of Oral and Maxillofacial Surgery **57**(6): 683.

<http://www.sciencedirect.com/science/article/B6WKF-4CRR5T0-DM/2/8d77e1a217a1eb6cc10b2bb554627bdf>

Purpose: Reactive arthritis (ReA) as a consequence of triggering Chlamydia trachomatis infections has been extensively studied to better understand inflammatory arthritis. This study investigated whether the presence of C trachomatis can be shown in the TMJ of patients with internal derangement. **Patients and Methods:** Posterior bilaminar tissue removed from 31 patients (29 F, 2 M) during TMJ articular disc repositioning and posterior ligament repair was tested for the presence of C trachomatis. Cryosections were stained using a monoclonal antibody that identifies all chlamydial serovars. Highly specific polymerase chain reaction (PCR) assays independently targeting two genes of p p]C trachomatis also were performed; these assays also identify all serovars of this organism. **Results:** TMJ tissue from 6 of 30 patients (20%) showed the presence of C trachomatis in the posterior bilaminar tissue on immunostaining. PCR screening identified 12 of 31 patients (39%) as having C trachomatis DNA in tissue, including four of six positive by immunostaining. All chlamydia-positive patients were female, with an average age of 36.7 years (15 to 48 years). **Conclusions:** The presence of C trachomatis in the human TMJ has not been previously shown. The presence of this organism may serve as the pathogenetic mechanism for TMJ dysfunction, as demonstrated in other joints. Nonapparent chlamydial infection in females may also explain the marked prevalence of TMJ symptoms in women.

Honda, M. J., T. Yada, et al. (2004). "Cartilage formation by serial passaged cultured chondrocytes in a new scaffold: Hybrid 75:25 poly(L-lactide-[epsilon]-caprolactone) sponge." Journal of Oral and Maxillofacial Surgery **62**(12): 1510.

<http://www.sciencedirect.com/science/article/B6WKF-4DW8KWB-M/2/fa8b7dc99ba7e3d23ab244ac144b7910>

Purpose This study was designed to determine whether multiplied chondrocytes immersed in a new scaffold, 75:25 poly(L-lactide-[epsilon]-caprolactone) sponge coated with type I collagen (75-PLC scaffold), could be used to generate cartilage tissue in vivo and to evaluate the correlation between cartilage generation and the phenotype of the proliferated chondrocytes. **Materials and methods** Rat chondrocytes were suspended in 75-PLC scaffold at a density of 1 X 10⁷ cells/mL after proliferation in a monolayer for 1 (P1) to 4 passages (P4) and implanted in nude mice for 4 weeks. Cells were characterized by the expression of genes encoding type II collagen, aggrecan, and type I collagen by Northern hybridization, and consequently, the newly formed tissue was evaluated histologically. **Results** The expression of aggrecan messenger RNA gradually decreased with the passaged cultures; however, the expression of type I collagen messenger RNA increased with time. The cartilage formations in all specimens were found not only in P1 chondrocytes but also in P2 chondrocytes, although when P3 chondrocytes were grafted, approximately 50% of cartilage formation was still observed up to but not beyond P4. **Conclusion** It is suggested that cartilage tissue is generated with cultured chondrocytes up to P2 but not beyond P4. Northern blot analysis is useful for the assessment of whether the cells are capable of regeneration.

Dahlgren, L. A., H. O. Mohammed, et al. (2005). "Temporal expression of growth factors and matrix molecules in healing tendon lesions." Journal of Orthopaedic Research **23**(1): 84.

<http://www.sciencedirect.com/science/article/B6W7R-4CSYJG1-4/2/a23f6670fd8312bc5ded4fdb0daf3bc9>

Overuse tendon injuries are common among elite and recreational athletes. Tendon healing may be enhanced at the cellular level through the use of exogenous growth factors; however, little is known about the endogenous expression of growth factors in healing tendon. This study describes the temporal expression of insulin-like growth factor-I (IGF-I), transforming growth factor- β 1 (TGF- β 1), and collagen types I and III in healing tendon lesions. Collagenase-induced lesions were created in the tensile region of the flexor digitorum superficialis tendon of both forelimbs of 14 horses. Tendons were harvested from euthanatized horses 1, 2, 4, 8 or 24 weeks following injury. Gene expression was evaluated using Northern blot analysis (collagen types I and III), real time PCR (IGF-I and TGF- β 1), and in situ hybridization. Protein content was assayed by dye-binding assay (collagen types I and III), radioimmunoassay (IGF-I), ELISA (TGF- β 1), and immunohistochemistry. Samples were also processed for differential collagen typing, DNA and glycosaminoglycan content, and routine H&E staining. Microscopically, lesions progressed from an amorphous, acellular lesion soon after injury to scar tissue filled with collagen fibers and mature fibroblasts organized along lines of tension. Early lesions were characterized by immediate increases in expression of growth factors and collagen. Message levels for TGF- β 1 peaked early in the wound healing process (1 week), while IGF-I peaked later (4 weeks), as the regenerative phase of healing was progressing. In the first 2 weeks after lesion induction, tissue levels of IGF-I protein actually decreased approximately 40% compared to normal tendon. By 4 weeks, these levels had exceeded those of normal tendon and remained elevated through 8 weeks. Message expression for collagen types I and III increased by 1 week following injury and remained elevated throughout the course of the study. Collagen type I represented the major type of collagen in healing tendon at all time points of the study. Based on these results, IGF-I, administered exogenously during the first 2 weeks following injury, may provide a therapeutic advantage by bolstering low endogenous tissue levels and enhancing the metabolic response of individual tendon fibroblasts.

Devine, M. J., C. M. Mierisch, et al. (2002). "Transplanted bone marrow cells localize to fracture callus in a mouse model." Journal of Orthopaedic Research **20**(6): 1232.

<http://www.sciencedirect.com/science/article/B6W7R-45J8WMW-3/2/30e36d99e7e38b1bf1b1a8187f8214d>

Bone marrow contains many cellular elements that may contribute to fracture repair. We used a

pluripotential stromal cell in a mouse model to demonstrate the presence of transplanted cells in fracture hematoma and subsequently in maturing fracture callus. Cells were transduced with traceable genes (lac Z and neomycin resistance) and traced in vivo after intravenous injection into syngeneic mice. These transduced cells home to bone marrow, suggesting that they might be detected in fracture callus. Cells were injected intravenously into mice and stabilized femoral shaft fractures were induced. Control mice received intravenous lactated-Ringer's solution prior to fracture. Callus tissue and marrow were examined histologically from 1 to 10 weeks after fracture to detect transplanted cells. Transplanted cells were detected in fracture callus in areas, and at times, of most active bone formation. Control specimens showed minimal staining of the callus tissue. Levels of the traceable gene in fracture callus increased, reached a peak between 3 and 4 weeks after fracture, then diminished and disappeared by 10 weeks post-fracture as woven bone at the fracture site was replaced by lamellar bone with cells from the host mouse. The results show that pluripotent bone marrow cells home to the marrow after systemic injection and localize in fracture callus.

Muramatsu, K. and A. T. Bishop (2002). "Cell repopulation in vascularized bone grafts." Journal of Orthopaedic Research **20**(4): 772.

<http://www.sciencedirect.com/science/article/B6W7R-44SJYB5-5/2/e0ba949f905fc6cd53c4369ac476c68e>

Following vascularized bone autografts, osteocyte viability is largely maintained. Viable cells within a graft may be surviving graft-derived cells, their progeny, or host-derived cells from circulation or surrounding bone. This study was conducted to define the process of cell repopulation, within vascularized bone grafts. Using inbred Lewis rats, 30 female vascularized tibial bones were transplanted to syngeneic male recipients and 45 male grafts were transplanted to female recipients. Twenty-five female recipients were immunosuppressed with FK506 to prevent rejection caused by Y-chromosome related antigens. The grafts were assessed up to 24 weeks post-transplant by radiography, histology and semi-quantitative polymerase chain reaction (PCR) using both Y-chromosome and autosome gene-specific primers. The female to male isograft transplants were useful to measure low levels of repopulation with host-derived cells, while male to female transplants more accurately quantified higher levels of cellular replacement. No host-derived cells were detected in the transplanted bone before six weeks. Thereafter, the ratio of host-derived cells gradually increased. By 24 weeks only 0.1-1.0% of graft-derived cells remained in the transplanted tibias. This study demonstrates that Y-chromosome-specific PCR is a useful tool to detect the cell lineage and cell repopulation following rat sex-mismatch vascularized bone grafting. Our results showed that donor cells in vascularized bone grafts were gradually repopulated with recipient cells. Correlation with histologic findings suggests that the periosteal hypertrophy observed by six weeks post-transplant results from graft-derived cells, while later remodeling is associated with host-derived cells.

Muramatsu, K., R. G. Valenzuela, et al. (2003). "Detection of chimerism following vascularized bone allotransplantation by polymerase chain reaction using a Y-chromosome specific primer." Journal

of Orthopaedic Research **21**(6): 1056.

<http://www.sciencedirect.com/science/article/B6W7R-48TKCBN-1/2/8afc05807dbc3bb578c4cb63f2666c4d>

Chimerism following allogeneic organ transplantation is a phenomenon known to occur and be associated with development of immunologic tolerance in allotransplantation. However, little is known about graft cell migration following vascularized bone allografting. In this study, chimerism was assessed following vascularized tibia transplantation from male DA or PVG donors to female PVG rat recipients using a semi-quantitative polymerase chain reaction for the Y-chromosome. FK-506 (Tacrolimus) was administered after transplantation for immunosuppression. All immunosuppressed PVG rat recipients of PVG bone grafts showed a high level of chimerism (1%) in the thymus, spleen, liver and cervical lymph nodes at 18 weeks post-transplant. Donor cells were also detected in the contralateral tibia and humerus. In non-immunosuppressed PVG rat recipients of DA bone grafts, donor cells were detected in the spleen in three of five rats within 2 weeks post-transplant. In these animals the bone grafts were severely rejected. In immunosuppressed PVG rat recipients of DA bone grafts, two of five, four of eight and eight of 10 rats showed low level chimerism (0.1%) in peripheral blood at 1, 12, and 18 weeks post-transplant. Six rats showed a high level of chimerism in the spleen and thymus. Histological studies revealed no rejection findings through 18 weeks post-transplant. Our results indicate that chimerism, or the presence of graft cells in host tissue, may occur in the face of acute rejection and be demonstrable following vascularized isograft and allograft living bone transplantation when chronic immunosuppression is maintained. Graft vascular patency during the short-term likely allows cellular migration, even in the face of acute rejection. Long-term survival and proliferation of graft marrow elements in host tissue may be possible with adequate immunosuppression.

Ara, T., T. Kusafuka, et al. (2000). "Determination of imbalance between MMP-2 and TIMP-2 in human neuroblastoma by reverse-transcription polymerase chain reaction and its correlation with tumor progression." Journal of Pediatric Surgery **35**(3): 432.

<http://www.sciencedirect.com/science/article/B6WKP-4C53P60-6/2/65523b87ca97365bd1e6884e14501f42>

Background/Purpose: The matrix metalloproteinases (MMPs) and their specific tissue inhibitors (TIMPs) have been implicated in tumor invasion and metastasis. Net matrix degradation and proteolysis depend on the critical local balance between MMPs/TIMP-2. We attempted to determine their expression balance and to evaluate its importance with tumor progression. **Methods:** Expressions of MMP-2, MMP-9, and TIMP-2 mRNAs was quantified by

reverse-transcription polymerase chain reaction (RT PCR) in tumor tissues from 25 neuroblastoma patients. Results: MMP-2, MMP-9, and TIMP-2 expression was observed in all the samples but with different trends. Increased expressions of MMP-2 mRNA was evident in advanced stages (Evans' stage III and IV; $P = .02$; unpaired ttest), and in patients who died of progressive disease ($P = .0001$). Whereas, the expressions of MMP-9 and TIMP-2 had no such significant association with clinical stages and prognosis. The ratio of MMP-2/TIMP-2 mRNAs was significantly higher in the advanced stages versus early stages (mean $\pm$ SD = 1.66 ± 0.65 and 1.11 ± 0.34 , respectively; $P = .02$) and in patients who died of progressive disease versus alive patients (mean = 2.13 ± 0.78 and 1.21 ± 0.36 , respectively; $P = .0006$). Conclusions: Coexpression of MMPs and TIMP-2 in neuroblastoma indicates the need to evaluate their expression balance. Significantly higher expression of MMP-2 mRNA and increased ratio of MMP-2 and TIMP-2 mRNAs in advanced stages or patients who have died of progressive disease suggests an association between elevated MMP-2 expression and poor prognosis. To establish the role of enzyme to inhibitor mRNA ratio as a reliable predictor, cohort studies with significant number of cases may be carried out.

Brizzolara, A., M. Torre, et al. (2004). "Histochemical study of Dom mouse: a model for Waardenburg-Hirschsprung's phenotype." *Journal of Pediatric Surgery* **39**(7): 1098.

<http://www.sciencedirect.com/science/article/B6WKP-4CN8TF3-P/2/e2725a66a6cedaf51afa3c3582e155f0>

Background/Purpose The spontaneous mouse mutant Dominant megacolon (Dom) represents the model of the Waardenburg-Hirschsprung's disease, a syndromic pathology, characterized by the association of pigmentation defects (PD), deafness, and Hirschsprung's disease (HD). The defect in Dom mouse is caused by a spontaneous mutation of the gene encoding the Sry-related transcription factor Sox10. This mutation affects several aspects of neural crest development leading to combined enteric innervation and pigmentation defects, both in mouse and human. The purpose of this report is to define, by enzymo-histochemical techniques routinely used for the diagnosis of human Hirschsprung's disease (AChE, LDH, NADPH-diaphorase), the innervative patterns of the affected gut. **Methods** Fifty-four siblings of Heterozygous Dom/+ mice underwent autopsy and were genotyped by direct sequencing of polymerase chain reaction (PCR) products for Sox10 mutations. The enteric nervous system of all the mice was studied by histochemical techniques indicated above. **Results** Genotyping showed that 43 mice were Dom/+ and 11 were Wild type +/+. Wild-type +/+ mice were used as control. The correspondence between genotype and at least 1 phenotypic aspect (PD or dysganglionosis) was present in 93% of cases (41 of 43). Among the Dom/+ mice, dysganglionosis was present in 79% of cases and PD in 90% of cases. Moreover, among Dom/+ mice, excluding those whose mantle was not evaluated as dead just after birth, PD and dysganglionosis (complete phenotype) were present in 68% of cases. **Conclusions** The histochemical methods that we used proved to be useful for identification of different aganglionic (AG), hypoganglionic (HG), and normoganglionic segments of Dom/+ mouse gut studied in longitudinal sections. Unlike humans, control mice (Wild type +/+) presented a rich component of AChE nerve fibers, whereas Dom/+ mice with dysganglionosis presented a decrease in AChE-positive nerve fibers. These data confirm the variable phenotypic penetrance in heterozygous mice. Because dysganglionosis in this animal model (Dom/+) was evident in 79% of cases (AG or HG), we concluded that Dom mice could represent important models for further experimental studies.

Cass, D. L., T. M. Quinn, et al. (1998). "Increased cell proliferation and decreased apoptosis characterize congenital cystic adenomatoid malformation of the lung." *Journal of Pediatric Surgery* **33**(7): 1043.

<http://www.sciencedirect.com/science/article/B6WKP-4CTD5NV-H/2/d8274c1e8cdb959a3547d2e14388ed30>

Background/Purpose: Congenital cystic adenomatoid malformations (CCAM) are lung lesions that demonstrate abnormalities of both mesenchymal and epithelial tissues. The pathogenesis of these tumors remains unknown. Because normal organogenesis requires a balance between cell proliferation and programmed cell death (apoptosis), the authors hypothesized that CCAM results from an increase in cell proliferation or a decrease in apoptosis within the developing lung, possibly mediated by keratinocyte growth factor (KGF). **Methods:** To examine cell cycle control in CCAM, we measured indices of cell proliferation and apoptosis in lesions requiring fetal (n = 4) or neonatal (n = 8) resection compared with those of normal fetal (14 to 28 week's gestation; N = 14) and neonatal (n = 3) human lung. Cell proliferation was analyzed by immunostaining for a proliferation marker (Ki-67). Apoptosis was examined using an in situ digoxigenin end-labeling technique to localize apoptotic bodies. The expression of KGF protein and KGF mRNA in CCAM and normal lung was examined using immunohistochemistry and semiquantitative reverse transcriptase-polymerase chain reaction (RT-PCR). **Results:** CCAM lesions in general showed a twofold increase in cell proliferation index (19.2% $\pm$ 1.4% v 9.6% $\pm$ 0.7%, $P < 0.05$). **Conclusions:** These results demonstrate that CCAM differs from normal lung by increased cell proliferation and decreased apoptosis. The increased proliferation does not appear to be mediated by the pneumocyte mitogen KGF. An examination of factors that control cell proliferation and apoptosis in CCAM may provide further insight into the pathogenesis of this tumor.

Kusafuka, T. and P. Puri (1997). "Altered mRNA expression of the neuronal nitric oxide synthase gene in Hirschsprung's disease." *Journal of Pediatric Surgery* **32**(7): 1054.

<http://www.sciencedirect.com/science/article/B6WKP-4CR8G4W-X/2/7e3c796839beca6b803d51f783f27a5c>

Nitric oxide has been described as an inhibitory neurotransmitter to mediate smooth muscle relaxation in the mammalian gastrointestinal tract. The enzyme neuronal nitric oxide synthase (NOS) catalyzes the formation of NO. The authors examined the expression of neuronal NOS gene at the mRNA level in intestinal specimens from seven patients who had Hirschsprung's disease (HD) using reverse transcription polymerase chain reaction (RT-PCR) technique. With 35 cycles of PCR reaction, substantial signals of neuronal NOS mRNA were observed in the ganglionic bowel in all seven patients, whereas in the aganglionic bowel, neuronal NOS signals were weak in three patients, and undetectable in four patients. By increasing the PCR cycle to 40 cycles, barely detectable signals were observed in two of the latter four patients. Semiquantitative analysis in the three patients who showed weak signals with 35 cycles of PCR indicated that neuronal NOS mRNA expression in aganglionic bowel was decreased at least 1/50 to 1/100 of the level of expressed in ganglionic bowel. Because absence or low level of expression of neuronal NOS mRNA may lead to impaired production of NO, our observations suggest that motility dysfunction in HD may be as a result of markedly decreased or no expression of the neuronal NOS gene at the mRNA level.

Kusafuka, T. and P. Puri (1997). "Altered RET gene mRNA expression in Hirschsprung's disease." *Journal of Pediatric Surgery* **32**(4): 600.

<http://www.sciencedirect.com/science/article/B6WKP-4CT1124-6R/2/331f56b7618ff14ad8823b948f30a7f2>

The RET proto-oncogene is a major cause of Hirschsprung's disease (HD) as demonstrated by the experimentally produced intestinal aganglionosis in mice with a null mutation of this gene and by the increased evidence of RET mutations in patients with HD. To evaluate the possible implication of the RET gene for the development of HD, we examined mRNA expression level of the RET gene in the bowel specimen of seven HD patients by using the reverse transcription-polymerase chain reaction technique. A significantly less intense signal for RET mRNA was found in the aganglionic bowel compared with the ganglionic bowel. In the hypoganglionic transitional zone, the RET mRNA level was higher than that of an aganglionic segment but lower than that observed in the ganglionic portion. In two patients where semiquantitative analysis was performed, the RET mRNA level in the aganglionic bowels was estimated to be approximately 1/500 of that in the ganglionic bowels. Because expression of RET mRNA plays an important role in establishing the enteric neuronal lineage, decreased RET mRNA expression in the aganglionic bowel may suggest maldevelopment of neural crest-derived cells in Hirschsprung's disease.

Liechty, K. W., T. M. Crombleholme, et al. (1999). "Elevated platelet-derived growth factor-B in congenital cystic adenomatoid malformations requiring fetal resection." Journal of Pediatric Surgery **34**(5): 805.

<http://www.sciencedirect.com/science/article/B6WKP-4CR8H6R-DD/2/50b4b8c92b19029c9cc8d57dfe86d657>

Background: During lung development, platelet-derived growth factor-BB (PDGF-BB) is maximal during the canalicular stage and decreases by the sacular stage. PDGF-BB stimulates lung growth by increasing cell proliferation. Fetal CCAMs have been shown to have an elevated proliferative index, but it is not known why some CCAMs rapidly enlarge in utero and cause fetal hydrops. The authors hypothesized that the high proliferative index and rapid enlargement of some fetal CCAMs may be caused by persistently elevated PDGF-BB production compared with normal fetal lung. **Methods:** To test this hypothesis, tissue was obtained at the time of resection from two fetal CCAMs (22 weeks), three full-term CCAMs, and three normal fetal lungs (21 to 22 weeks). PDGF-BB production by fetal CCAMs was compared with normal age-matched fetal lung using immunohistochemistry, reverse transcriptionase-polymerase chain reaction (RT-PCR), and Western blot analysis. **Results:** CCAMs resulting in fetal hydrops and requiring fetal resection had strong mesenchymal immunostaining for PDGF-BB next to epithelial lined cysts, increased PDGF-B gene expression by RT-PCR, and elevated PDGF-BB protein by Western blot, compared with normal age-matched fetal lung. Term CCAMs had minimal PDGF-BB staining, PDGF-B gene expression, and PDGF-BB protein production. **Conclusions:** CCAMs that grew rapidly and progressed to hydrops, requiring in utero resection, demonstrated increased mesenchymal PDGF-B gene expression and PDGF-BB protein production compared with age-matched normal fetal lung, which may, in part, be responsible for the autonomous growth and proliferation seen in hydropic fetal CCAMs.

Mason, J. E., P. J. Goodfellow, et al. (2000). "16q loss of heterozygosity and microsatellite instability in Wilms' tumor." Journal of Pediatric Surgery **35**(6): 891.

<http://www.sciencedirect.com/science/article/B6WKP-49SHG13-35/2/92a38ee43453a7ea3d166366a6fb99fa>

Background/Purpose: Wilms' tumor is the most common renal malignancy of childhood. Loss of heterozygosity (LOH) at 16q is seen in about 17% of cases and has been associated with a poor prognosis. To more precisely define the pattern of 16q deletion exhibited by Wilms' tumor, the authors performed a detailed LOH analysis of 96 specimens using polymorphic microsatellite repeat markers. The authors also evaluated the neoplasms for the presence of microsatellite

instability (MSI). Methods: A total of 96 DNA samples were studied using polymerase chain reaction-based LOH analyses amplifying polymorphic microsatellite repeat markers. Screening for MSI using 2 additional genetic markers also was carried out. Results: The authors found 16q LOH in 14 of the specimens evaluated. Comprehensive analysis of these LOH-positive specimens showed a region of loss spanning 16p11.2-q22.1 and a separate distal region of LOH at 16q23.2-24.2. The distal region of deletion is very small, estimated to be approximately 2.4 megabases. In addition to the observed LOH, 2 specimens were found to consistently exhibit MSI, which has not been reported previously in Wilms' tumor. Conclusions: The smallest consensus region of deletion in our analysis of Wilms' tumor 16q LOH measures 2.4 megabases at 16q23.2-q24.2. Additionally, MSI was present in a subset of tumor specimens suggesting that defects in DNA mismatch repair may contribute to the pathogenesis of Wilms' tumor. *J Pediatr Surg* 35:891-897. Oue, T. and P. Puri (1999). "Altered endothelin-3 and endothelin-B receptor mRNA expression in hirschsprung's disease." *Journal of Pediatric Surgery* **34**(8): 1257.

<http://www.sciencedirect.com/science/article/B6WKP-4CP6TFB-6X/2/d68d92700b59011a345ab718db75b8c3>

Background: Recently, the endothelin-3 (EDN3) and endothelin-B receptor (EDNRB) gene have been recognized as susceptibility genes for Hirschsprung's disease (HD). However, gene mutations have been observed only in limited cases, and the role of EDN3 in the pathogenesis and motility dysfunction in HD is not understood fully. To evaluate the possible implication of EDN3 and EDNRB for the development of HD, we examined the EDN3 and EDNRB mRNA level in bowel specimens of HD patients. Methods: Entire resected specimens of colon were obtained from 14 patients with HD. Eight age-matched control patients without gastroenteric disorders also were examined. mRNA was extracted from ganglionic and aganglionic segments of the HD specimens and normal colons. Reverse transcription-polymerase chain reaction (RT-PCR) was performed to evaluate the relative amount of EDN3 and EDNRB mRNA. Results: In normal colon, constant EDN3 and EDNRB mRNA expression was observed. In HD, EDN3 and EDNRB mRNA expression was observed. In HD, EDN3 and EDNRB mRNA levels were decreased both in ganglionic and aganglionic segment in 2 cases. In 6 cases, EDN3 mRNA expression was decreased in aganglionic segment and in another 2 cases, EDNRB mRNA expression was decreased in aganglionic segment. In the remaining 4 cases, EDN3 and EDNRB mRNA levels were similar to controls. Conclusion: The authors' findings indicate that loss of EDN3 and EDNRB function may be involved in the maldevelopment of neural crest-derived cells causing HD in many patients.

Piotrowska, A. P., V. Solari, et al. (2003). "Distribution of Ca²⁺-Activated k⁺ channels, SK2 and SK3, in the normal and Hirschsprung's disease bowel." *Journal of Pediatric Surgery* **38**(6): 978.

<http://www.sciencedirect.com/science/article/B6WKP-48NBHVV-1B/2/e813bf59396e4ba0573f0ded69edcf28>

Purpose: The aim of this study was to investigate the expression and distribution of SK2 and SK3 channels in the normal and Hirschsprung's disease (HD) bowel. Methods: Full-thickness colonic specimens were collected at pull-through operation from 10 patients with HD and from 6 patients during bladder augmentation. Reverse transcriptase-polymerase chain reaction (RT-PCR) analysis for SK2 and SK3 channels and double immunostaining using anti SK2/c-kit, SK3/c-kit, SK2/[alpha]-SMA, and SK2/PGP 9.5 antibodies was performed. Immunolocalization was detected using laser scanning microscopy. Results: RT-PCR analysis showed strong expression of SK2 and SK3 mRNA in the normal human bowel and significantly reduced SK3 expression in the

aganglionic bowel (P Conclusions: The results of this study provide the first evidence for the presence of SK2 and SK3 channels and for the immunocolocalization of SK3 channels in the ICCs in the normal human colon. Decreased expression SK3 channels in the aganglionic bowel may contribute to motility dysfunction in HD.

Quinn, T. M., K. G. Sylvester, et al. (1999). "TGF-[beta]2 is increased after fetal tracheal occlusion." Journal of Pediatric Surgery **34**(5): 701.

<http://www.sciencedirect.com/science/article/B6WKP-4CR8H6R-CS/2/611882acee24d34f5c15132498ef7902>

Background/Purpose: Fetal tracheal occlusion (TO) accelerates lung growth in normal and hypoplastic fetal lung. The mechanism of accelerated lung growth remains unknown but may be a result of growth factor induction. Previous studies of growth factors induced by tracheal ligation have characterized mRNA rather than protein expression. Although the transforming growth factor-[beta] (TGF-[beta]) family participates in normal lung morphogenesis, its role in lung growth after TO is unclear. The authors hypothesize that TGF-[beta] expression is increased with TO and may contribute to the accelerated lung growth seen after TO. **Methods:** Diaphragmatic hernia (DH) was created in 80-day-gestation sheep (n = 6; term, 145) by excising the left diaphragm. At 110 days, the trachea was occluded (n = 4) with a clip. DH controls (n = 2) were not occluded. Fetuses were killed at 139 days, and lung samples were snap frozen for tissue analysis. Non-DH control lungs were harvested from full-term animals (n = 2). TGF-[beta] mRNA was analyzed by semiquantitative reverse transcriptionase--polymerase chain reaction (RT-PCR). TGF-[beta] protein was assessed by Western blot analysis. **Results:** TGF-[beta]1 mRNA and protein were not increased with tracheal ligation compared with either non-DH or DH controls. TGF-[beta]2, however, was markedly increased, at both the mRNA and protein level, in ligated lungs compared with nonligated controls. **Conclusions:** TGF-[beta]2 protein, but not TGF-[beta]1, is increased in the hypoplastic lungs of fetal sheep after tracheal occlusion. Increased TGF-[beta]2 expression appears to result from increased or prolonged expression of mRNA transcripts. This is the first study to document a change in growth factor protein levels after TO. Increased TGF-[beta]2 expression may contribute to accelerated lung growth and decreased surfactant production observed after tracheal occlusion.

Safford, S. D., A. J. Freerman, et al. (2005). "Decreased E-cadherin expression correlates with higher stage of Wilms' tumors." Journal of Pediatric Surgery **40**(2): 341.

<http://www.sciencedirect.com/science/article/B6WKP-4FH06RR-B/2/c0d35520406291e8273e9e9ab76de649>

Purpose The aim of this study was to examine the association between E-cadherin expression and markers of Wilms' tumor aggression, including metastasis and recurrence. **Methods** Forty Wilms' tumor samples from the National Wilms' Tumor Study Group underwent immunohistochemical staining for E-cadherin. Tumor stage at diagnosis, recurrence, and loss of heterozygosity at 16q status was known for each of the tumor samples. E-Cadherin cell staining was defined as high (>33%) or low (Results Wilms' tumors presenting with metastatic (stage IV) disease demonstrated decreased levels of E-cadherin expression compared with localized tumors (stage I) (Fisher's Exact test, P Conclusions In this study, the authors have found an association between decreased E-cadherin expression and metastatic Wilms' tumor. Mutations identified may help identify a mechanism for downregulation. The functional significance of these mutations is supported by the conserved nature of the amino acids across multiple species. The authors believe these findings support the involvement of E-cadherin in the evolution of Wilms' tumor.

Solari, V. and P. Puri (2004). "Genetic polymorphisms of angiotensin system genes in congenital diaphragmatic hernia associated with persistent pulmonary hypertension." Journal of Pediatric Surgery **39**(3): 302.

<http://www.sciencedirect.com/science/article/B6WKP-4BT1J8H-B/2/5de3502302e1d8fa581162ff20e39c65>

Background/purposeThe renin-angiotensin system plays an important role in pulmonary artery remodelling. Several polymorphisms of genes encoding for components of the renin angiotensin system such as the angiotensin converting enzyme (ACE), the angiotensinogen (AGT) gene, and the angiotensin II type 1 receptor (AT1R) have been associated with the development of pulmonary hypertension. The aim of this study was to investigate the ACE I/D genotype, the M235 T polymorphism of the AGT gene and the A1166 C polymorphism of AT1R in the lungs of congenital diaphragmatic hernia (CDH) complicated by persistent pulmonary hypertension (PPH) in the newborn. **Methods**Genomic DNA was extracted from archival paraffin-embedded lung tissue from 13 newborns with CDH complicated by PPH and from 9 controls. Genotyping for the I/D-ACE, the M235 T-AGT, and the A1166 C-AT1R gene polymorphisms were determined by a polymerase chain reaction-based method with appropriate restriction digest when required. **Results**In controls, ACE genotype distribution of DD, ID, and II was 11%, 33%, and 55%, respectively, whereas in CDH it was 70%, 15%, and 15%, respectively. The ACE-DD genotype was significantly higher in CDH compared with controls (P < 0.05). **Conclusions**These data suggest that D allele of the ACE gene insertion/deletion polymorphism and angiotensinogen M235 T polymorphism may be associated with PPH in newborns with congenital diaphragmatic hernia.

Spilde, T. L., A. M. Bhatia, et al. (2004). "Aberrant fibroblast growth factor receptor 2 signalling in esophageal atresia with tracheoesophageal fistula." Journal of Pediatric Surgery **39**(4): 537.

<http://www.sciencedirect.com/science/article/B6WKP-4C2PRK5-6/2/3b85b36f672971d5520dfa80524afd88>

BackgroundAlthough the pathogenesis of esophageal atresia with tracheoesophageal fistula (EA/TEF) remains unknown, it has been shown that despite its esophageal appearance, the fistula tract originates from respiratory epithelium. The authors now hypothesize that defects in fibroblast growth factor (FGF) signaling contribute to the esophaguslike phenotype of the fistula tract. FGF2R is critical to normal lung morphogenesis and occurs in 2 isoforms (FGF2RIIIb and FGF2RIIIc), each with different ligand-binding specificity. To characterize FGF signaling in the developing EA/TEF, the authors analyzed levels of FGF2R splice variants in experimental EA/TEF. **Methods**The standard Adriamycin-induced EA/TEF model in rats was used. Individual foregut components from Adriamycin-treated and control embryos were processed for real-time, fluorescence-activated semiquantitative reverse transcriptase polymerase chain reaction on gestational days 12.5 and 13.5. **Results**Both fistula tract and Adriamycin-treated or normal esophagus showed significantly lower levels of FGF2RIIIb than either Adriamycin-treated lung buds (E12.5, P = .02; E13.5, P = .001). **Conclusions**Levels of FGF2R in the developing fistula tract resemble that of distal esophagus rather than developing lung. This defect in FGF2RIIIb signaling may account for the nonbranching, esophaguslike phenotype of the fistula, despite its respiratory origin.

Taira, Y., T. Oue, et al. (1999). "Increased tropoelastin and procollagen expression in the lung of nitrofen-induced diaphragmatic hernia in rats." Journal of Pediatric Surgery **34**(5): 715.

<http://www.sciencedirect.com/science/article/B6WKP-4CR8H6R-CW/2/97913541194d61856d52a8c7faf9c794>

Background/Purpose: Collagen and elastin, the predominant components of the lung connective tissue network, have been suggested to have an important influence on lung compliance and maximal expansion. Decrease in lung compliance and distensibility often is seen in human congenital diaphragmatic hernia (CDH) lung as well as in experimentally produced CDH lung. The aim of this study was to investigate mRNA levels of tropoelastin and [alpha]1 (I) procollagen, the precursors of elastin, and type I collagen, respectively, in CDH lung and to determine whether antenatal dexamethasone treatment has any effect on the production of these extracellular matrix proteins. **Methods:** CDH model was induced in pregnant rats after administration of 100 mg nitrofen on day 9.5 of gestation (term, 22 days). Dexamethasone (0.25 mg/kg) was given on day 18.5 and 19.5. Cesarean section was performed on day 21. The fetuses were divided into three groups: group I, normal controls; group II, nitrofen-induced CDH; and group III, nitrofen-induced CDH with antenatal dexamethasone treatment. Reverse transcription-polymerase chain reaction (RT-PCR) was performed to evaluate relative amounts of tropoelastin and [alpha]1 (I) procollagen mRNA. **Results:** Levels of both tropoelastin and [alpha]1 (I) procollagen mRNA were significantly increased in group II compared with group I (P < 0.05). **Conclusions:** The increased local synthesis of tropoelastin and type I procollagen in CDH lung may be responsible for the increased rigidity and decreased compliance observed in the CDH hypoplastic lung. Glucocorticoids have no effect on pulmonary tropoelastin and [alpha]1 (I) procollagen gene expression in CDH lungs.

Journal of Pharmaceutical and Biomedical Analysis (5)

Arakawa, H., A. Tsuji, et al. (1997). "Analysis of single-strand conformation polymorphisms by capillary electrophoresis with laser induced fluorescence detection." Journal of Pharmaceutical and Biomedical Analysis **15**(9-10): 1537.

<http://www.sciencedirect.com/science/article/B6TGX-3W0FSK8-4R/2/d8aa7b79ec12e5c82f780aabd6f9d66a>

Detection of point mutations in genomic DNA is important for diagnosis of inherited characteristics and genetic diseases. A point mutation in a specific region of DNA amplified by polymerase chain reaction (PCR) can be detected with single-strand conformation polymorphism (SSCP) analysis. Analysis of SSCP by laser-induced fluorescence capillary electrophoresis in entangled polymer solution (CE-LIF) has been developed in the present paper. K-ras genes including seven mutations were amplified with primer labeled with Texas Red at its 5' end. The labeled PCR products were dissociated to single strands by heating and separated with capillary gel electrophoresis and He-Ne laser-excited fluorescence detection. Our results suggest that all fragments having normal (Gly) and mutated (Ala, Arg, Cys, Ser, Val, Asp) sequences at codon 12 can be distinguished. Analysis of SSCPs with CE-LIF is well suited for clinical analysis of SSCPs because of its high sensitivity, resolution, reproducibility and speed.

Lauwers, S., Y. Vander Heyden, et al. (2002). "Screening and optimisation of an ELISA method for the quantitative detection of enterovirus specific RT-PCR products by means of a two-level experimental design." Journal of Pharmaceutical and Biomedical Analysis **29**(4): 659.

<http://www.sciencedirect.com/science/article/B6TGX-45JYJC6-F/2/0e1e018a4a32672b457a910209872898>

In a previous paper, optimal reaction conditions were determined for the RT-PCR part of a quantitative enterovirus specific RT-PCR ELISA method (J. Pharm. Biomed. Anal., 25 (2001) 131-142). In order to obtain a detection limit as low as possible, the ELISA part of the procedure was optimised as well. This was done by investigating the influence of seven factors at three levels in a multivariate approach. A reflected two-level screening design, derived from a Plackett-Burman design, was used. Optimal reaction conditions were established by calculation and by evaluation of the effects of the factors on the measured absorbance of the ELISA detection. Under these conditions, the linear range and detection limit of the test were determined and compared with the ELISA conditions before optimisation. The optimised RT-PCR ELISA will be used to study a possible longitudinal relationship between enteroviruses and the development of multiple sclerosis and juvenile diabetes.

Lauwers, S., Y. Vander Heyden, et al. (2001). "Screening of an enterovirus specific RT-PCR ELISA method for the quantification of enterovirus genomes in human body fluids by means of a three-level experimental design." Journal of Pharmaceutical and Biomedical Analysis **25**(1): 131.

<http://www.sciencedirect.com/science/article/B6TGX-42M7828-J/2/6637db87972d5e7573113fb04e43c931>

In order to obtain a detection limit as low as possible for a quantitative enterovirus specific RT-PCR ELISA assay, optimal reaction conditions, which give rise to the highest response, need to be determined. This was done by investigating the influence of 13 factors, selected from RT and PCR, in a multivariate approach by means of a well-balanced three-level screening design, derived from a three-level Plackett-Burman design. Optimal reaction conditions could be determined by calculation and evaluation of the effects of the different factors on the response, i.e. the measured absorbance of the ELISA detection. The method will be used to study a possible longitudinal relationship between enteroviruses and the development of multiple sclerosis and juvenile diabetes.

Verheyden, B., S. Lauwers, et al. (2003). "Quantitative RT-PCR ELISA to determine the amount and ratio of positive- and negative strand viral RNA synthesis and the effect of guanidine in poliovirus infected cells." Journal of Pharmaceutical and Biomedical Analysis **33**(2): 303.

<http://www.sciencedirect.com/science/article/B6TGX-492098W-3/2/ea0a9c5bb172d82c9c65c6cad3e056f7>

Quantitative reverse transcription-polymerase chain reaction enzyme linked immunosorbent assay (RT-PCR ELISA) is the method of choice to study positive- and negative strand viral RNA synthesis during poliovirus replication. In comparison with other methods used for this purpose, it fulfils all necessary requirements to accurately determine RNA of different polarity. It combines high specificity, high sensitivity, safety, speed, and the ability to perform quantitative analysis. The enterovirus specific RT-PCR ELISA method described in this work, was used to determine quantitatively the amount of de novo poliovirus positive- and negative strand RNA synthesis at different time-points in the viral replication cycle, both in presence and absence of the viral RNA synthesis inhibitor guanidine hydrochloride.

Verheyden, B., A. Thielemans, et al. (2003). "RNA extraction for quantitative enterovirus RT-PCR: comparison of three methods." Journal of Pharmaceutical and Biomedical Analysis **33**(4): 819.

<http://www.sciencedirect.com/science/article/B6TGX-4950CBP-5/2/687d80ab93c70773bbca05b0b890c902>

Quantification of virus-like RNA sequences in biological fluids, like serum and cerebrospinal fluid, requires an RNA extraction method that is both reproducible and fast. Three RNA extraction methods were tested on enteroviruses: (1) the acid guanidine thiocyanate-phenol/chloroform (AGPC) method; (2) a method based on differential precipitation of the RNA and (3) a 'bind-wash-elute' system based on silica-gel membrane binding. The latter two methods yielded a comparable detection limit as measured by RT-PCR ELISA. The detection limit for the AGPC method was 10 times higher. The relative standard deviation for the bind-wash-elute method (3%) was superior to that of the other methods tested (both 20%) and provides a reliable and fast method to extract (viral) RNA from biological fluids for quantification by RT-PCR.

Cotreau, M. M., L. L. von Moltke, et al. (2000). "Methodologies to study the induction of rat hepatic and intestinal cytochrome P450 3A at the mRNA, protein, and catalytic activity level." Journal of Pharmacological and Toxicological Methods **43**(1): 41.

<http://www.sciencedirect.com/science/article/B6T8S-41PP0J6-6/2/6e9142ddaecb9a6a3ee1ba22bd48972b>

Studies were conducted to characterize assays for the isolation and quantitation of rat cytochrome P450 (CYP) 3A isoforms from hepatic and intestinal tissues. Isolated intestinal microsomes were analyzed for their alkaline phosphatase activity and CYP 3A immunoreactivity. The involvement of CYP 3A in the in vitro hydroxylation of midazolam (MDZ) was also evaluated using isoform specific chemical and antibody inhibitors. The effect of glycerol (a common constituent of the microsomal reconstitution buffer) concentration on in vitro MDZ hydroxylation was also investigated. Additionally, to verify that the intestinal preparation was adequate for use in studies investigating the induction of CYP3A at the mRNA, protein, and catalytic activity within a single animal, a separate induction study was carried out with the CYP 3A inducer dexamethasone (DEX). A reverse transcription-polymerase chain reaction (RT-PCR) assay and a quantitative Western blotting method were used to reliably detect differences in CYP 3A mRNA and immunoreactivity between DEX- and vehicle (VH)-treated tissues. The in vitro hydroxylation of MDZ evaluated CYP 3A catalytic activity and identified increases in CYP 3A activity caused by DEX in comparison to VH. Collectively, these described techniques provide an experimental model to study xenobiotic induction of rat hepatic and intestinal CYP 3A from the molecular to the catalytic level in individual rats without the need for pooling of tissue.

Davies, A., E. Whiting, et al. (1995). "The application of the human beta-globin gene locus control region and murine erythroleukemia cell system to the expression and pharmacological characterization of human endothelin receptor subtypes." Journal of Pharmacological and Toxicological Methods **33**(3): 153.

<http://www.sciencedirect.com/science/article/B6T8S-3YMWF3D-F/2/deda4e36ab68af617fb165a2284a3798>

The cDNAs encoding both A and B subtypes of the human endothelin receptor have been inserted into mammalian cell expression vectors that utilize the human globin gene, locus control region. These constructs have been introduced into murine erythroleukemia cells and inducible high level expression of the receptors has been achieved (~1.5-pM/mg membrane protein and ~13,500 binding sites/cell for both receptor subtypes). Cell lines expressing these receptors were obtained on a rapid time scale (3-4 weeks), facilitated by the need for the analysis of only small numbers of cell clones/receptor (~6). Competitive binding assays with endothelin-1 gave IC₅₀s of 130 +/- 30 pM for endothelin-A receptor and 160 +/- 30 pM for endothelin-B receptor. Similar studies with the different isoforms of endothelin, sarafatoxin-S6b and -S6c, BQ123 and BQ3020, all gave the expected selectivity profiles. The IC₅₀s for all compounds were in close agreement with those reported for native receptors. Thus, this expression system, which has several advantages over other described expression systems, is capable of rapidly providing large quantities of receptor for detailed pharmacological analyses or drug screening. In addition, the expressed receptors display the expected pharmacological profiles in the absence of any complicating, competing interactions from other subtypes or binding sites.

Piette, J. (1992). "Molecular analysis of mutations induced by 4'-hydroxymethyl-4,5',8-trimethylpsoralen and UVA in the mouse HPRT gene." Journal of Photochemistry and Photobiology B: Biology **12**(1): 37.

<http://www.sciencedirect.com/science/article/B6TH0-44K8208-5/2/9b362dbc93a487920381ee71cb3d2d35>

The effects of the reaction photosensitized by 4'-hydroxymethyl-4,5',8-trimethylpsoralen (HMT) on a mouse lymphoma cell line have been examined. Using the hypoxanthine phosphoribosyltransferase (HPRT) locus as target gene, a mutagenic effect of the photoreaction can be detected concomitantly with a loss of cell viability. Isolation of HPRT deficient clones has permitted a molecular characterization of the mutational pattern induced by the photosensitization reaction mediated by HMT. Southern blotting analysis demonstrated that the HPRT deficiency could not be correlated with gene deletions larger than 300 bp. Using polymerase chain reaction on both DNA and cDNA, amplification products have been cloned into M13mp18 and sequenced. Base transversions targeted on thymine residues have been located in exon 2, 3, 8 and 9 together with spontaneous frameshift mutations occurring in a run of guanine residues in exon 3. HPRT deficiencies owing to mutations arising in the HPRT promoter region have also been observed. Dot and Northern blot analysis revealed that the photoreaction could lead to either a reduced level of gene transcription or to a complete absence of HPRT m-RNA. Using polymerase chain reaction (PCR) amplification and agarose gel electrophoresis, deletions in the HPRT promoter have been observed and correlated to deficient enzyme expression.

Journal of Psychiatric Research (1)

Heilig, M., O. Zachrisson, et al. (2004). "Decreased cerebrospinal fluid neuropeptide Y (NPY) in patients with treatment refractory unipolar major depression: preliminary evidence for association with preproNPY gene polymorphism." Journal of Psychiatric Research **38**(2): 113.

<http://www.sciencedirect.com/science/article/B6T8T-49H1HKV-4/2/3d6cb50b9a82fb94fd4a08e5228ee5bd>

Extensive animal studies suggest neuropeptide Y (NPY) to be involved in coping with a wide range of stressors, and that impaired central NPY signalling could be involved in the pathophysiology of anxiety and depression. Human studies of central NPY levels in depression have, however, been inconclusive. Here, we examined levels of NPY-like immunoreactivity (NPY-LI) in the cerebrospinal fluid (CSF) of medication-free subjects with treatment refractory unipolar depression. Patients were admitted to a research inpatient unit, examined under standardized conditions, and compared with a sample of volunteers in whom psychiatric morbidity was excluded. A robust suppression of NPY levels in patient CSF was found, while other putative CSF markers (monoamine metabolites, somatostatin) did not differ between the groups. We then explored whether this finding might be related to a recently described T1128C coding polymorphism which results in a Leu7-> Pro7 substitution of the signal peptide, and a previously not described T -399C polymorphism in the promoter region of the preproNPY gene. Preliminary evidence was found for an association of both markers with a diagnosis of depression, indicating the possibility of an underlying haplotype influencing the vulnerability for developing depressive illness. Our present findings are in line with an extensive animal literature, and further support the notion that impaired NPY function could contribute to depressive illness.

Journal of Reproductive Immunology (4)

de Luca Brunori, I., L. Battini, et al. (2003). "HLA-DR in couples associated with preeclampsia: background and updating by DNA sequencing." Journal of Reproductive Immunology **59**(2): 235.

<http://www.sciencedirect.com/science/article/B6T8W-48M7VYN-5/2/bb92e190d0abb5e883c4626b995548f3>

The placenta acts as an immunological barrier between the mother and the fetal "graft", allowing two antigenically different organisms to tolerate one another. In placentae from preeclamptic women, we have demonstrated, by an ultrastructural assessment and an immunohistochemical study, a placental barrier breakage leading to the mixing of maternal and fetal antigenically different blood. This condition could be responsible for the triggering of a maternal rejection reaction that we presume to be at the basis of the preeclamptic syndrome. Thus, we have investigated the Human Leukocyte class II DR antigens (HLA-DR), whose role in self and non-self recognition is well known, in women with preeclampsia, their partners and in control couples using the serological Terasaki technique. The results showed a statistically significant increase of HLA-DR homozygosity and a reduced antigenic variety in the preeclamptic women and their partners with respect to controls. In this update, we have examined the 2nd exon of the human gene, HLA-DRB1, on the short arm of the chromosome 6 using DNA sequence-based typing (S-BT) PCR in 56 preeclamptic couples and 64 control couples. The results have confirmed the significant excess of HLA-DR homozygosity in couples associated with preeclampsia versus controls. From our results, it emerges that HLA-DR homozygosity and the reduced antigenic

variety seem to be associated to a major risk for preeclampsia, which further appears to be a "couple's disease".

Muciaccia, B., A. Filippini, et al. (1998). "Testicular germ cells of HIV-seropositive asymptomatic men are infected by the virus." Journal of Reproductive Immunology **41**(1-2): 81.

<http://www.sciencedirect.com/science/article/B6T8W-3V5TKM2-7/2/3c7a90b4a25564e1b60dbe8ea00d858b>

In situ PCR hybridization studies in the testis of infected asymptomatic subjects detected the presence of HIV-1 proviral DNA in the nuclei of germ cells at all stages of differentiation suggesting that HIV-seropositive men produce infected spermatozoa that are released in the genital tract. In all subjects studied spermatogenesis was normal, the presence of provirus was not associated with germ cell damage and a very mild local immune response was observed. The HIV hybridization pattern observed in germ cells supports the hypothesis of a clonal infection. It is suggested the possibility of a direct infection of the germ cells by cell-free virus and that the testis might represent a site of early viral localization, well tolerated because of the immune privilege of this organ.

Pudney, J., H. Nguyen, et al. (1998). "Microscopic evidence against HIV-1 infection of germ cells or attachment to sperm." Journal of Reproductive Immunology **41**(1-2): 105.

<http://www.sciencedirect.com/science/article/B6T8W-3V5TKM2-9/2/7f7894481a17e8f3e332256650954531>

For a number of years we have intensively investigated the localization of HIV-1 in male genital tract tissues and secretions using a variety of microscopy techniques including immunocytochemistry, in situ hybridization, in situ PCR and electron microscopy. Our studies have failed to demonstrate an association between HIV-1 and either testicular germ cells or spermatozoa. In this article we present our results in the context of other related studies, and discuss the strengths and weaknesses of the techniques that have been used to address this important research question.

van den Elsen, P. J., S. J. P. Gobin, et al. (2001). "Transcriptional control of MHC genes in fetal trophoblast cells." Journal of Reproductive Immunology **52**(1-2): 129.

<http://www.sciencedirect.com/science/article/B6T8W-445B4KX-C/2/418e8b800184a4dca8115a505815001f>

Tight control of MHC expression is essential for the outcome of a successful pregnancy. The lack of MHC class II and class I mediated antigen presentation by fetal trophoblast cells is an important mechanism to evade maternal immune recognition. Interestingly, the deficient expression of MHC class II molecules (HLA-DR, -DQ and -DP) and of the classical MHC class I molecules HLA-A and HLA-B is also noted after IFN-[gamma] treatment in trophoblast-derived cell lines. Our studies show that in trophoblast cell lines the IFN-[gamma] induced transactivation of HLA-A and HLA-B promoters is repressed. Furthermore, it was found that trophoblast cells lacked IFN-[gamma] mediated induction of the class II transactivator (CIITA). This lack of CIITA expression in trophoblast cells is due to CIITA promoter hypermethylation. In addition to lack of CIITA expression, trophoblast cells also displayed a repressed expression of RFX5. Together,

these observations reveal a silencing of multiple activation pathways that are critical to the transcriptional control of MHC class II and class I antigen presentation functions by trophoblast cells.

Journal of Surgical Research (4)

Cheuk, B. L. Y. and S. W. K. Cheng (2004). "Differential expression of integrin [alpha]5[beta]1 in human abdominal aortic aneurysm and healthy aortic tissues and its significance in pathogenesis." Journal of Surgical Research **118**(2): 176.

<http://www.sciencedirect.com/science/article/B6WM6-4C7W8HT-9/2/a16aaf722abd4917999cc100bf268faf>

Background Abdominal aortic aneurysm (AAA) is a common aged disease of human aorta with increasing incidence. It is characterized by dramatic vascular remodeling via proteolysis and degradation of matrix proteins. Integrins are important cellular receptors for matrix proteins, which may have an association with pathological remodeling. The present study was undertaken to analyze the expression of integrin subunits in human aneurysmal aortas and with healthy aortic tissues as controls. **Materials and methods** The expression of integrin genes in AAA specimens and healthy human aortic tissues was detected by RT-PCR technique. The correlation of variation and distribution of smooth muscle cells (SMCs) and integrin protein expression in the corresponding tissues were studied immunohistochemically. **Results** The gene transcripts coding for integrin [alpha]4, [alpha]5, [alpha]V, [beta]1, [beta]3, [beta]5, and [beta]6 subunits were constitutively expressed in the normal aortas. Only gene expressions of integrin [alpha]5 and [beta]1 were significantly decreased by 81% and 85%, respectively, in AAA specimens (P < 0.05). **Conclusions** The marked decrease in integrin [alpha]5[beta]1 expressions was unique to aneurysmal aortic tissues and correlated to a decrease in density of SMCs, which are the major cells in maintaining the structure stability of normal aortas. As integrin [alpha]5[beta]1 specifically binds fibronectin and collagen, those results may suggest that the absence of integrin [alpha]5[beta]1 activity impair matrix protein attachment and alter the architecture in aortic media thereby lead to the deformity of aorta and aneurysm formation.

Concolino, P., V. Papa, et al. (2004). "The unsolved enigma of CDH1 down-regulation in hereditary diffuse gastric cancer." Journal of Surgical Research **121**(1): 50.

<http://www.sciencedirect.com/science/article/B6WM6-4CTCV63-F/2/7cd716cf028a4cbec7e0b82fc7203301>

Background Hereditary diffuse gastric cancer (HDGC) is a disease mediated by down-regulation of the tumor suppressor E-cadherin (CDH1). This disease is particularly dangerous because of the youth of the patients, and for clinical management, hampered by the submucosal spread of tumor invisible at endoscopy. Two mechanisms of CDH1 down-regulation have been described in HDGC: missense mutations in the CDH1 gene and gene silencing through promoter methylation. **Materials and methods** Seven patients affected by HDGC were enrolled. Tumor tissues were checked for CDH1 expression by immunohistochemistry (IHC). CDH1 DNA sequencing was performed for all its 16 exons from tumor and normal tissues of the same patients to detect somatic and germ-line mutations. Methylation promoter study was performed

using specific primers and PCR. Results IHC analysis confirmed CDH1 down-regulation in all patients. DNA sequencing revealed the presence of six missense mutations in five patients. Four mutations were at the EC-3 domain of CDH1, whereas the other two were found in the cytoplasmic region interacting with catenins. All six mutations were absent in normal tissue, thereby excluding its presence in germ-line cells. Four patients exhibited both DNA missense mutations and gene silencing through promoter methylation. In two patients we did not notice either DNA missense mutations or promoter methylation. Conclusion CDH1 somatic mutations and promoter methylation synergistically induce CDH1 down-regulation in HDGC patients, whereas germ-line mutations are relatively rare. However, other unknown mechanisms of CDH1 suppression are involved to explain CDH1 down-regulation in HDGC patients without CDH1 mutations and promoter methylation.

Knight, R. J., H. Liu, et al. (2003). "Cold ischemic injury, aortic allograft vasculopathy, and pro-inflammatory cytokine expression." Journal of Surgical Research **113**(2): 201.

<http://www.sciencedirect.com/science/article/B6WM6-49D6P0F-4/2/36f963684e96fb1e970ead996330283f>

Background The aim of this study was to understand the role of ischemic preservation injury and pro-inflammatory cytokine expression in the progression of allograft vasculopathy. Methods Using the rat aortic transplant model, grafts were stored at 4[deg]C for either 1 or 24 h. Graft vasculopathy was assessed at 4 and 8 weeks after transplantation. Intra-graft cytokine expression was measured at days 1, 3 and, 7 after transplantation. Results At 4 weeks, intimal hyperplasia of allografts was greater than isografts (P P P P Conclusions Prolonged ischemic preservation injury induced vascular disease in both isografts and allografts. The vessel wall reaction increased over time and was greater in allografts than isografts. The enhanced expression of T cell- and macrophage associated cytokines in allografts compared to isografts, suggested that early pro-inflammatory cytokine expression played an important role in progression of allograft vasculopathy.

Martin, R. C. G., Q. Lan, et al. (2005). "No apparent association between genetic polymorphisms (-102 C>T) and (-9 T>C) in the human manganese superoxide dismutase gene and gastric cancer1." Journal of Surgical Research **124**(1): 92.

<http://www.sciencedirect.com/science/article/B6WM6-4DS45W9-6/2/8fb09387391d5143bb21550c9a6a1f20>

Background Manganese superoxide dismutase (MnSOD) plays a critical role in the detoxification of mitochondrial reactive oxygen species, constituting a major cellular defense mechanism against agents that induce oxidative stress. A genetic polymorphism in the mitochondrial targeting sequence of this gene has been associated with increased cancer risk. This one base pair transition (-9 T>C) leads to a Val to Ala amino acid change in the mitochondrial targeting sequence. In addition, the MnSOD promoter contains an activator protein-2 (AP-2) binding site that modifies transcription of MnSOD. Mutations have been identified in the proximal region of the promoter in human tumor cell lines. One of these mutations (-102 C>T) has been shown to change the binding pattern of AP-2, leading to a reduction in transcriptional activity. The aim of our study was to investigate possible associations of the (-9 T>C) and (-102 C>T) polymorphisms with gastric cancer in a population-based case-control study conducted in Warsaw, Poland. Materials and methods DNA was obtained from a population based case-control study of stomach cancer conducted in Warsaw, Poland, between 1994 and 1996. The MnSOD -9 T>C genotype was determined by PCR-RFLP assay. The MnSOD -102 C>T genotype was determined using a TaqMan allele discrimination assay. Results The frequency of the -102 C>T

polymorphism was 41% (38/91) in gastric cancer cases and 38% (50/130) in the controls (odds ratio [OR] 1.1, 95% confidence interval [CI] 0.6-2.1). The frequency of the -9 T>C polymorphism was 44% (202/464) in cases and 56% (262/464) in controls (OR 1.1; 95% CI 0.9-1.37). The lack of association was observed in both non-smokers (OR 1.5; 95% CI 0.7-2.34) and smokers (OR 1.1; 95% CI 0.7-1.7). Furthermore, the association was not significant when smokers were segregated by extent of smoking history. Conclusion The association of the manganese superoxide dismutase polymorphisms at -102 C>T and the -9 T>C were not found to be associated with gastric cancer in a Polish case-control study.

Journal of the American College of Cardiology (7)

Lanfear, D. E., S. Marsh, et al. (2004). "Genotypes associated with myocardial infarction risk are more common in African Americans than in European Americans." Journal of the American College of Cardiology **44**(1): 165.

<http://www.sciencedirect.com/science/article/B6T18-4CRXMCG-14/2/22fa828d6747f2122439d18feb24e20b>

Objectives This study was designed to describe the frequencies of multiple myocardial infarction (MI) risk-associated genotypes among different racial groups. **Background** Racial disparities in the prevalence of cardiovascular disease (CVD) are well known. Recent large Japanese case-control studies identified connexin-37 (GJA-4), plasminogen activator inhibitor-1 (PAI-1), and stromelysin-1 (MMP-3) polymorphisms as risk factors for MI, but the prevalence of these genotypes among different racial groups in the U.S. needs to be determined. **Methods** Genomic deoxyribonucleic acid from 95 healthy African Americans (AA) and 95 healthy European Americans (EA) was used for genotyping. Deoxyribonucleic acid containing the region of interest was amplified using the polymerase chain reaction, followed by genotyping using pyrosequencing. **Results** All three MI-risk genotypes were observed in both populations and were in Hardy-Weinberg equilibrium. The frequencies of two of the three "risk-associated" genotypes were significantly higher in the AA population: GJA4 C1019T T/T: AA, 20%, EA, 7% ($p = 0.053$); MMP3 -1171delA A/A: AA, 78%, EA, 24% (p Conclusions We found higher frequencies of disease-associated genotypes in AA than in EA. Our results also show that more AA than EA carry multiple risk-associated genotypes. Future studies need to assess whether such genetic profiles predict adverse outcomes in U.S. populations and contribute to racial disparities in CVD burden.

Maekawa, Y., T. Anzai, et al. (2004). "Effect of granulocyte-macrophage colony-stimulating factor inducer on left ventricular remodeling after acute myocardial infarction." Journal of the American College of Cardiology **44**(7): 1510.

<http://www.sciencedirect.com/science/article/B6T18-4DFJDW5-Y/2/598ddd89fb0c0bdc2b6fd3745eb18b1>

Objectives We sought to determine the influence of granulocyte-macrophage colony-stimulating factor (GM-CSF) induction on post-myocardial infarction (MI) remodeling, especially in relation to the inflammatory response and myocardial fibrosis. **Background** Granulocyte-macrophage colony-stimulating factor modifies wound healing by promoting monocytopoiesis and infiltration of

monocytes and macrophages into injured tissue; however, the effect of GM-CSF induction on the infarct healing process and myocardial fibrosis is unclear. **Methods** A model of MI was produced in Wistar rats by ligation of the left coronary artery. The MI animals were randomized to receive GM-CSF inducer (romurtide 200 [μg/kg/day for 7 consecutive days) (MI/Ro) or saline (MI/C). **Results** Echocardiographic and hemodynamic studies on day 14 revealed increased left ventricular (LV) end-diastolic dimension, decreased fractional shortening, elevated LV end-diastolic pressure, and decreased LV maximum rate of isovolumic pressure development in MI/Ro compared with MI/C. Immunoblotting showed that expression of transforming growth factor (TGF)-[β]1 in the infarcted site on day 3 after MI was decreased in MI/Ro compared with MI/C. In the infarcted site, TGF-[β]1, collagen type I and type III messenger ribonucleic acid (mRNA) expression on day 3, and collagen content on day 7 were reduced in MI/Ro compared with MI/C, in association with marked infarct expansion. In MI/Ro, monocyte chemoattractant protein-1 mRNA level and the degree of infiltration of monocyte-derived macrophages (ED-1-positive) were greater in the infarcted site on day 7 than those in MI/C. **Conclusions** The GM-CSF induction by romurtide facilitated infarct expansion in association with the promotion of monocyte recruitment and inappropriate collagen synthesis in the infarcted region during the early phase of MI.

Ramet, M. E., M. Ramet, et al. (2003). "High-density lipoprotein increases the abundance of eNOS protein in human vascular endothelial cells by increasing its half-life." Journal of the American College of Cardiology **41**(12): 2288.

<http://www.sciencedirect.com/science/article/B6T18-48VWB6W-13/2/9e63bb568aa2fd42644186c27e8f057b>

Objectives Given the importance of endothelial nitric oxide synthase (eNOS) in regulating endothelium-dependent vasorelaxation, we investigated the effects of high-density lipoprotein in (HDL) on eNOS protein abundance in cultured human vascular endothelial cells. **Background** Endothelial dysfunction, characterized by decreased nitric oxide production, is one of the early features in the development of atherosclerosis. We have recently shown in vivo that niacin therapy increases plasma HDL concentration and improves endothelium-dependent vasorelaxation in patients with coronary artery disease. **Methods** Human vascular endothelial cells were cultured in the presence or absence of HDL or apolipoprotein (apo)A-I. The eNOS protein abundance was assessed by immunoblotting, and protein half-life was assessed by pulse-chase techniques. The eNOS messenger ribonucleic acid (mRNA) abundance was measured using real-time quantitative polymerase chain reaction. **Results** High density lipoprotein, or apoA-I alone, increased eNOS protein abundance by 3.5 ± 0.7 and 2.7 ± 0.5-fold, respectively (p < 0.05). **Conclusions** We demonstrate that HDL activates both extracellular signal-regulated kinase 1/2 (ERK1/2) and Akt, resulting in enhanced eNOS protein stability and subsequent accumulation of eNOS protein. This posttranslational regulation represents a previously unrecognized mechanism for regulating eNOS.

Rott, D., J. Zhu, et al. (2003). "Effects of MF-tricyclic, a selective cyclooxygenase-2 inhibitor, on atherosclerosis progression and susceptibility to cytomegalovirus replication in apolipoprotein-E knockout mice." Journal of the American College of Cardiology **41**(10): 1812.

<http://www.sciencedirect.com/science/article/B6T18-48MY548-Y/2/f54e71994f434526274490ddf9c9c9>

Objectives We examined whether selective cyclooxygenase-2 (COX-2) inhibition in apolipoprotein-E (apoE) deficient mice reduces cytomegalovirus (CMV) replication, and determined whether COX-2 anti-inflammatory activity leads to decreased atherosclerosis. **Background** Evidence suggests that CMV infection contributes to atherosclerosis

and that this occurs in part through inflammatory mechanisms. Cyclooxygenase-2 inhibitors are potent anti-inflammatory agents. They also inhibit CMV replication in vitro. **Methods** The apoE deficient mice were either treated or not treated with a selective COX-2 inhibitor, and either infected or not infected with CMV. Viral deoxyribonucleic acid load in salivary glands was determined by quantitative polymerase chain reaction. Atherosclerotic lesion analysis was performed by standard methods. **Results** In vivo COX-2 inhibition, unexpectedly increased viral load: in the CMV-infected animals viral load was 2.58 ± 1.0 in the nontreated group, 4.74 ± 1.38 in the group treated with 12 mg/kg/day MF-tricyclic, and 6.51 ± 1.64 in the group treated with 24 mg/kg/day MF-tricyclic (p TREND = 0.050). This increased viral load was paralleled by increased anti-CMV antibody titers. Most surprisingly, COX-2 inhibition significantly increased early atherosclerotic lesion area, independent of viral infection. **Conclusions** Our study demonstrates that selective inhibition of COX-2 in vivo increases viral load. The finding that inhibition of COX-2 increases atherosclerosis development in apoE deficient mice suggests, unexpectedly, that this enzyme exerts antiatherosclerosis activity, at least in this model.

Seko, Y., N. Kayagaki, et al. (2002). "Role of Fas/FasL pathway in the activation of infiltrating cells in murine acute myocarditis caused by Coxsackievirus B3." Journal of the American College of Cardiology **39**(8): 1399.

<http://www.sciencedirect.com/science/article/B6T18-45JG5R2-VI2/a50824b196aded16025e642bdf8f4628>

Objectives This study was designed to investigate the roles of Fas/FasL pathway in myocardial damage in murine acute myocarditis caused by Coxsackie virus B3 (CVB3). **Background** Cardiac myocyte apoptosis rarely occurs in murine acute myocarditis caused by CVB3. Fas/FasL belong to the tumor necrosis factor receptor/ligand superfamily of costimulatory molecules and are known to play a critical role in the induction of apoptosis, as well as in the cytotoxicity mediated by T-cells and natural killer cells. **Methods** We first analyzed the expression of Fas on cardiac myocytes in vivo and in vitro. Second, we examined the development of myocardial damage, in C3H/He mice treated with an anti-FasL monoclonal antibody (mAb), and in C3H/He-lpr/lpr mice and C3H/He-gld/gld mice infected with CVB3. Third, to investigate the effects of anti-FasL mAb treatment on the activation of the infiltrating cells, we examined the expression of interferon (IFN)-gamma and interleukin (IL)-2 as activation markers in the heart of mice by semiquantitative polymerase chain reaction. **Results** Fas was markedly induced on cardiac myocytes with acute myocarditis. Myocardial inflammation was decreased in mice treated with anti-Fas L mAb, C3H/He-lpr/lpr mice and C3H/He-gld/gld mice. Anti-FasL mAb-treatment also decreased the expression of IFN-gamma, IL-2, inducible nitric oxide synthase and CVB3 genomes in myocardial tissue. **Conclusions** Our findings strongly suggested that the Fas/FasL pathway played a critical role in the development of massive myocardial necrosis through activation of infiltrating cells, and raise the possibility of immunotherapy by blocking the Fas/FasL pathway to prevent myocardial damage and improve the prognosis of patients with viral myocarditis.

Snapir, A., P. Heinonen, et al. (2001). "An insertion/deletion polymorphism in the [alpha]2b-adrenergic receptor gene is a novel genetic risk factor for acute coronary events." Journal of the American College of Cardiology **37**(6): 1516.

<http://www.sciencedirect.com/science/article/B6T18-42VM8NN-4/2/d1a318e6e10b6f975142a43157efb60f>

OBJECTIVES Our aim was to study whether an insertion/deletion (I/D) polymorphism in the [alpha]2B-adrenoceptor gene is associated with the risk for cardiovascular diseases. **BACKGROUND** [alpha]2-adrenoceptors mediate contraction of vascular smooth muscle

and induce coronary vasoconstriction in humans. The α_2 -adrenoceptor subtype B mediates vasoconstriction in mice. A variant of the human α_2B -adrenoceptor gene that encodes a D of three residues in an intracellular acidic motif has been shown to confer decreased receptor desensitization. This receptor variant could, therefore, be involved in diseases associated with enhanced vasoconstriction.

METHODS This study was part of a prospective population-based study investigating risk factors for cardiovascular diseases in a cohort of middle-aged men from eastern Finland. Nine hundred twelve men aged 46 to 64 years were followed for an average time of 4.5 years.

RESULTS In this study population, 192 men (21%) had the D/D genotype; 256 (28%) had the I/I genotype, and 464 (51%) had a heterozygous genotype. In a Cox model adjusting for other coronary risk factors, men with the D/D genotype had 2.2 times (95% confidence interval: 1.1 to 4.4, $P = 0.02$) the risk to experience an acute coronary event ($n = 15$ for D/D, 10 for I/I and 12 for I/D) compared with men carrying either of the other two genotypes. The α_2B -adrenoceptor genotype was not associated with hypertension in this study population.

CONCLUSIONS The D/D genotype of the α_2B -adrenoceptor is a novel genetic risk factor for acute coronary events, but not for hypertension.

Yousufuddin, M., D. J. Cook, et al. (2004). "Angiotensin II receptors from peritransplantation through first-year post-transplantation and the risk of transplant coronary artery disease." Journal of the American College of Cardiology **43**(9): 1565.

<http://www.sciencedirect.com/science/article/B6T18-4C8G0WD-D/2/0a1a5579de6369ece47c3cb341d952e4>

Objectives We evaluated whether the angiotensin II (Ang II) receptors from perioperation through one-year post-transplantation predict the transplant coronary artery disease (TCAD) progression.

Background The role of Ang II receptors (type 1: AT1R; type 2: AT2R) in TCAD is uncertain.

Methods We investigated 28 heart donors and the corresponding recipients. The levels of AT1R and AT2R messenger ribonucleic acid (mRNA) were examined in lymphocytes from the donor spleen and in the donor heart at one-week and one-year posttransplantation to determine their association with the progression of TCAD, measured as changes in maximal intimal thickness (CMIT) and plaque volume (CPV) by intravascular ultrasound (IVUS) examinations.

Results The AT1R mRNA in lymphocytes from the donor spleen (CMIT: $R = 0.73$, $p = 0.001$); AT2R mRNA in the donor hearts at one-year post-transplantation (CMIT: $R = 0.3$, $p = 0.001$); AT1R mRNA in lymphocytes and in the donor hearts at one-year post-transplantation proved to be multivariate predictors of the progression of TCAD.

Conclusions These data suggest a role for Ang II receptors in the pathogenesis of TCAD and support a novel concept that TCAD may have its origin in the donor per se and may be modulated by the recipient's inherent biological factors.

Journal of the American College of Surgeons (2)

Abe, T., M. Oka, et al. (2001). "Interleukin-6 production in lung tissue after transthoracic esophagectomy." Journal of the American College of Surgeons **192**(3): 322.

<http://www.sciencedirect.com/science/article/B6T91-42G0MFJ-5/2/cb9d5e7f504a3a35eef7488b82d77b9c>

Background: The mechanisms of the reported high increase in interleukin-6 (IL-6) levels after

esophagectomy are unclear. We investigated the influence of an intrathoracic procedure, esophagectomy, on IL-6 production in lung tissue. Study Design: Fourteen paired lung tissue samples were obtained from patients before and after they underwent transthoracic esophagectomy for esophageal cancer. IL-6 levels in the lung were measured with enzyme-linked immunosorbent assay, and IL-6 mRNA expression was determined with real-time quantitative reverse transcription-polymerase chain reaction. Immunohistochemical staining was used to localize IL-6, and circulating levels were also measured. Results: IL-6 protein and mRNA were significantly increased in lung tissue after this intrathoracic procedure (p Conclusions: Transthoracic esophagectomy causes an increase in IL-6 production from airway epithelial cells, secondary to increased expression of IL-6 mRNA. Local response of lung tissue may be one source of increased serum IL-6 after this procedure.

Schneider, S., K. Uchida, et al. (2005). "Downregulation of TS, DPD, ERCC1, GST-Pi, EGFR, and HER2 gene expression after neoadjuvant three-modality treatment in patients with esophageal cancer." Journal of the American College of Surgeons **200**(3): 336.

<http://www.sciencedirect.com/science/article/B6T91-4FJT8T9-6/2/cba5a2216cfcc27129b32e6d18a0fc1b>

Background To find out if neoadjuvant therapy could alter tumor response determinants that might affect tumor sensitivity to the treatment, we investigated intratumoral expressions of genes associated with chemosensitivity, radiosensitivity, or both before and after radiochemotherapy. Study design Twenty-four patients with locally advanced, resectable esophageal cancer (cT2-4, Nx, M0) received neoadjuvant 5-FU/cisplatin/36 Gy treatment followed by transthoracic en bloc esophagectomy. Expression levels of thymidylate synthase, dihydropyrimidine dehydrogenase, excision repair cross-complementing gene 1, glutathione S-transferase Pi, epidermal growth factor receptor, and HER2 were measured in matched preradiochemotherapy endoscopic tumor biopsies and in postradiochemotherapy resection specimens. mRNA was isolated from formalin-fixed, paraffin-embedded, laser microdissected tumor tissues, and a quantitative fluorescent dye real-time reverse transcription polymerase chain reaction system was used for gene expression measurement. Results There was a significant reduction in the expression levels of thymidylate synthase (p Conclusions The expression levels of a set of genes that are possible determinants of 5-FU/cisplatin/radiation therapy antitumor activity are significantly downregulated by neoadjuvant radiochemotherapy in esophageal cancer.

Journal of the American Society for Mass Spectrometry (2)

Benson, L. M., A. P. Null, et al. (2003). "Advantages of thermococcus kodakaraensis (KOD) DNA Polymerase for PCR-mass spectrometry based analyses." Journal of the American Society for Mass Spectrometry **14**(6): 601.

<http://www.sciencedirect.com/science/article/B6TH2-48CX6M7-4/2/afe37edd9ff93709f981110b7b967ffc>

The advantages of the thermostable DNA polymerase from *Thermococcus kodakaraensis* (KOD) are demonstrated for PCR amplification with subsequent detection by mass spectrometry. Commonly used DNA polymerases for PCR amplification include those from *Thermus aquaticus*

(Taq) and *Pyrococcus furiosus* (Pfu). A 116 base-pair PCR product derived from a vWA locus was amplified by Taq, Pfu, or KOD DNA polymerase and compared by agarose gel electrophoresis and electrospray ionization Fourier transform ion cyclotron resonance mass spectrometry (ESI-FTICR-MS). KOD DNA polymerase demonstrated a 2- to 3-fold increase in PCR product formation compared to Pfu or Taq, respectively, and generated blunt-ended PCR product which allows facile interpretation of the mass spectrum. Additionally, we demonstrate the advantage of using high magnetic fields to obtain unit resolution of the same 116 base pair (~72 kDa) PCR product at high m/z.

Frahm, J. L., D. C. Muddiman, et al. "Leveling response factors in the electrospray ionization process using a heated capillary interface." Journal of the American Society for Mass Spectrometry **In Press, Corrected Proof** <http://www.sciencedirect.com/science/article/B6TH2-4FNP2J5-3/2/0f6262ef8376dfc211464d005fae41a6>

Several investigators have observed a discrepancy in electrospray response of complementary strands from denatured DNA, which has been attributed to the difference in hydrophobicity between the two strands; the more hydrophobic species tend to have higher ion abundances. The implementation of a heated electrospray source has allowed us to "level" the electrospray response for two equimolar complementary strands with different hydrophobicities. As the temperature was increased, the ratio of ion abundances of the less hydrophobic noncoding strand to the more hydrophobic coding strand approached unity. Furthermore, the heated electrospray source was used to denature amplicons containing 7-deaza purines, which can be used to facilitate sequencing by mass spectrometry.

Journal of the Association for Laboratory Automation (2)

Bitner, R., S. Koller, et al. (2004). "Purifying genomic DNA from whole blood on automated, high-throughput, and moderate-throughput platforms." Journal of the Association for Laboratory Automation **9**(2): 64.

<http://www.sciencedirect.com/science/article/B75DF-4CWYXY8-7/2/68b585b938a4cd8655bedef2a9530e90>

We describe three new automated methods for purifying genomic DNA from whole blood. The MagneSil(R) Blood Genomic, Max Yield System uses MagneSil(R) paramagnetic particles (PMPs) in a 96-well format to purify the maximal amount of DNA from a 200- μ L blood sample. In contrast, the MagneSil(R) ONE, Fixed Yield Blood Genomic System uses MagneSil(R) Fixed Yield PMPs to purify a normalized amount of DNA from 60 μ L of blood in a 96-well format. These methods are implemented on the Beckman Coulter Biomek(R) FX automated workstation. The MagneSil(R) KF Genomic System uses MagneSil(R) PMPs to purify DNA from 1 to 15 samples of 200- μ L blood using the moderate-throughput Thermo Electron KingFisher(R) mL instrument. The MagneSil(R) Blood Genomic System typically yields > 4 μ g per 200 μ L of whole blood, depending on the white blood cell content. The MagneSil(R) ONE System is best suited where there is a requirement for purification of a narrow concentration range of DNA. This system purifies 1 μ g (+/-50%) of DNA from 60 μ L of blood. The MagneSil(R) KF System purifies 2 to 6 μ g of DNA from 200 μ L of blood. DNA purified using all of these methods is suitable for PCR, STR, READIT(R) SNP genotype analysis, and multiplexed PCR analysis.

Ugaz, V. M. and M. Krishnan (2004). "Novel convective flow based approaches for high-throughput PCR thermocycling." Journal of the Association for Laboratory Automation **9**(5): 318.

<http://www.sciencedirect.com/science/article/B75DF-4DGSX88-F/2/f94319647f53ba0f2942cc81a6f7de13>

A critical need exists for the development of next-generation genomic analysis instrumentation capable of offering significantly higher throughput at a lower cost than current technology. In this paper, we explore the potential of natural convection-based systems to address these issues by providing a thermocycling hardware platform capable of performing rapid polymerase chain reaction (PCR) amplification of DNA. These systems can be arrayed in a multi-well format that is simple to operate, is suitable for integration with high-throughput automated liquid handling systems, and can be easily and inexpensively mass-produced.

Journal of the Autonomic Nervous System (2)

Ivanov, T. R., J. Cay Jones, et al. (1998). "Characterization of a partial cDNA clone detected by imidazoline receptor-selective antisera." Journal of the Autonomic Nervous System **72**(2-3): 98.

<http://www.sciencedirect.com/science/article/B6T05-3V5D7XB-6/2/4470612ad752851cfe3896e509d4afae>

A cDNA clone has been isolated from a human hippocampal cDNA expression library by relying on the selectivity of two antisera that are specific for imidazoline binding proteins. A 1789 bp cDNA clone was sequenced and shown to contain a single open-reading frame that predicts a 66 kDa polypeptide, but it is truncated based on its lack of a stop codon and poly-A+ tail. Two regions of homology exist for the predicted amino acid sequence in common with chromogranin-A and B proteins, a zinc finger protein, and the ryanodine receptor. Northern blot analyses of poly-A+ mRNA from 36 human tissues indicated two differentially expressed transcripts of 6.0 and 9.5 kb. The 6.0 kb mRNA form was enriched in brain and endocrine tissues as compared to other tissues, but not in strict concordance with 11-imidazoline binding sites. The highest overall amounts of the combined transcripts were found in pituitary. In situ hybridization histochemistry revealed an enrichment of the message in neuronal cell bodies of the rat hippocampus and cerebellar cortex. This clone has some of the properties expected of an imidazoline receptor.

Tajti, J., R. Uddman, et al. (1999). "Messenger molecules and receptor mRNA in the human trigeminal ganglion." Journal of the Autonomic Nervous System **76**(2-3): 176.

<http://www.sciencedirect.com/science/article/B6T05-3WS61Y5-F/2/935e4aa9c2abdfef18cf12a5ef36f2a7>

The presence and distribution of neuromessenger molecules and receptor mRNA in human trigeminal ganglion was studied with immunocytochemical, in situ hybridisation and RT-PCR techniques. Immunofluorescence staining revealed that calcitonin gene-related peptide (CGRP) immunoreactive (-ir) neurons occurred in high numbers, constituting 36-40% of all nerve cell

bodies in the ganglion. Accordingly, in situ hybridisation demonstrated CGRP mRNA in a large portion of the trigeminal neurons. A small number of the nerve cell bodies showed substance P (SP)-ir, (18%), nitric oxide synthase (NOS)-ir (15%), and pituitary adenylate cyclase activating peptide (PACAP)-ir (20%). Double immunostaining revealed that only few CGRP-ir neurons also were NOS-ir (less than 5%). The C-terminal flanking peptide of neuropeptide Y, C-PON, was not visible in any of the nerve cell bodies studied. Agarose gel electrophoresis of the RT-PCR products from the ganglia demonstrated the presence of mRNA corresponding to CGRP1, NPY Y1 and Y2, and VIP1 receptors. These results suggest both sympathetic and parasympathetic influence on the activity in the trigeminal ganglion.

Journal of the European Academy of Dermatology and Venereology (1)

Ward, K. A., S. A. McKernan, et al. (1995). "Concurrent oral and genital infection with HPV DNA types 6 and 11 in a heterosexual male." Journal of the European Academy of Dermatology and Venereology **4**(2): 160.

<http://www.sciencedirect.com/science/article/B6T92-3YS87RM-12/2/32edbaf43861c3f336f15407ba83573f>

Objective Detection of HPV DNA in oral and genital lesions of a heterosexual male, 4 months after oral and vaginal intercourse with a woman with vulvar warts. Possible modes of acquisition of oral HPV infection in the male sexual partner are discussed. Setting Genitourinary Medicine clinic. Methods Polymerase chain reaction amplification of genomic DNA from oral and genital lesions. HPV DNA typing by dot blot hybridization. Results HPV DNA types 6 and 11 were identified in a polypoid tongue lesion and in a penile wart from the male sexual partner. Conclusions The acquisition of oral HPV infection in the male sexual partner may have resulted from genital-oral HPV transfer, either by direct contact with vulvar warts or by digital self-inoculation.

Journal of the Neurological Sciences (25)

Aarskog, N. K., S. Aadland, et al. (2001). "Molecular genetic analysis of Charcot-Marie-Tooth 1A duplication in Norwegian patients by quantitative photostimulated luminescence imaging." Journal of the Neurological Sciences **188**(1-2): 21.

<http://www.sciencedirect.com/science/article/B6T06-43P3TH0-5/2/00060d51d9f36eff1cd4e1c970bff0eb>

Around 70% of Charcot-Marie-Tooth 1 (CMT1) cases are caused by a dominantly inherited 1.5-Mb duplication at 17p11.2-12 (CMT1A). Using photostimulated luminescence (PSL) imaging of MspI Southern blots, hybridization signals of the probe pVAW409R3a in relation to cohybridized probe SF85a, were densitometrically quantified and an RFLP allele-band ratio determined. A total of 55 Norwegian CMT patients and 16 asymptomatic family members from 26 separate families,

clinically and neurophysiologically classified as CMT1 (n=46) and CMT2 (n=9), were studied. Thirty-two of 46 CMT1 cases (69.6%), all heterozygous but one homozygous for the pVAW409R3a MspI polymorphism, from 12 of 21 families (57.1%) were positive for the CMT1A duplication. In autosomal dominant familial cases (n=30), 26 of 30 cases (86.7%), all heterozygous, from six of seven families (85.7%) were positive for duplication. None of the CMT2 patients, asymptomatic family members or healthy controls were positive for duplication. The CMT1A frequency of duplication in Norwegian CMT1 patients is in general agreement with those reported in other European countries and the present results show that quantitative densitometric PSL imaging is a highly reliable test in diagnosing CMT1A duplication.

Aguilera, I., J.-R. Garcia-Lozano, et al. (2001). "Mitochondrial DNA point mutation in the COI gene in a patient with McArdle's disease." Journal of the Neurological Sciences **192**(1-2): 81.

<http://www.sciencedirect.com/science/article/B6T06-44BM9KY-C/2/e19f34509d3a0206c5a9d73ce0f28a3c>

We studied a 57-year-old female patient with clinical and biochemical evidences of McArdle's disease. Her muscle biopsy also revealed signs of mitochondrial proliferation, scattered RRF, and a deficit in complex I of the respiratory chain. Molecular genetic analysis showed that the patient was heterozygous for the most common mutation at codon 49 in the myophosphorylase gene. Mitochondrial DNA analysis of muscle tissue revealed an additional G-to-A transition at nucleotide position 7444 in the cytochrome c oxidase subunit I (COI) gene.

Andrews, W. D., A. Al-Chalabi, et al. (1997). "Lack of evidence for HTLV tax-rex DNA in motor neurone disease." Journal of the Neurological Sciences **153**(1): 86.

<http://www.sciencedirect.com/science/article/B6T06-3RSFG7M-H/2/b5b8e086e8c597b99f814412e4dddf1d>

It has recently been claimed (Ferrante et al., 1995. HTLV tax-rex DNA and antibodies in idiopathic amyotrophic lateral sclerosis. J. Neurol. Sci. 129 (Suppl.) 140-144) that human T-lymphotropic virus (HTLV) tax-rex sequences are detectable in the peripheral blood mononuclear cells (PBMCs) of 40% of patients with motor neurone disease (MND). In an attempt to confirm this we employed a highly sensitive 'nested' polymerase chain reaction (PCR) assay, capable of detecting single molecules of HTLV proviral DNA, to look for tax-rex sequences in the PBMCs of 43 patients with MND. We were unable to detect the presence of HTLV tax-rex in any of 43 MND patients tested, using three different PCR primer sets under both high and low stringency conditions. Using the same DNA samples we were able to detect the presence of the single-copy pyruvate dehydrogenase gene, thus demonstrating that the extracted DNA was indeed amplifiable by PCR. To further exclude the possibility that the extracted DNA samples contained unrecognised inhibitory factors we conducted spiking experiments with trace amounts (approximately 10 copies) of HTLV proviral DNA. Spiked samples yielded PCR products of the expected size. We are therefore unable to confirm the presence of HTLV tax-rex sequences in this disease.

Cooper, J. M., V. M. Mann, et al. (1992). "Analyses of mitochondrial respiratory chain function and mitochondrial DNA deletion in human skeletal muscle: Effect of ageing." Journal of the Neurological Sciences **113**(1): 91.

<http://www.sciencedirect.com/science/article/B6T06-485RNBW-JT/2/3ed21d2856150c8fce6e9fb8c3541b53>

The analysis of human skeletal muscle mitochondria revealed a progressive decline in mitochondrial respiratory chain function with age. The activities affected to the greatest extent were those of complexes I and IV which were decreased by 59% and 47% respectively between the ages of 20-30 years and 60-90 years of age. Quantitation of the 5 kb 'common' deletion of mtDNA using PCR revealed a progressive accumulation with age, from approximately 1 in 100 000 at 21 years to 1 in 10 000 at 56 years and 1 in 5000 at 78 years of age. The low absolute levels of this mutation are unlikely to contribute significantly to the observed mitochondrial dysfunction.

Del Bo, R., G. P. Comi, et al. (1997). "The apolipoprotein E [epsilon]4 allele causes a faster decline of cognitive performances in Down's syndrome subjects." Journal of the Neurological Sciences **145**(1): 87.

<http://www.sciencedirect.com/science/article/B6T06-3R8617F-2M/2/42d17e0ee4afc598e8ebfae532b04d31>

The apolipoprotein E gene (APOE), located on human chromosome 19, has three common alleles ([epsilon]2, [epsilon]3, [epsilon]4) which encode for the three main isoforms indicated as E2, E3 and E4 respectively. Several findings indicate [epsilon]4 allele as an important risk factor in both sporadic and familial late-onset Alzheimer's disease (AD). Pathological changes similar to AD are seen in almost all patients with Down's syndrome (DS) aged over 35 (senile plaques, neurofibrillary tangles and neuronal loss); a proportion of these may subsequently develop dementia. Aim of this study is to evaluate the possible pathological role of [epsilon]4 allele as risk factor for developing AD in a DS population. ApoE [epsilon]4 allele frequency is not significantly different in DS cases and controls. We found a statistically significant inverse correlation between full scale IQ values and age of patients in the subgroup of DS subjects selected for the presence of at least one [epsilon]4 allele, while no correlation was observed in DS subjects with other ApoE genotypes. A longitudinal analysis of cognitive performances (available in 38 patients) showed a faster rate of decline in intellectual ability in those subjects carrying at least one [epsilon]4 allele. Our data support the hypothesis that ApoE [epsilon]4 allele has a contributory role in accelerating the mental deterioration of AD-type in DS patients. (c) 1997 Elsevier Science B.V.

Duggan, D. J., M. Fanin, et al. (1996). "[alpha]-Sarcoglycan (adhalin) deficiency: complete deficiency patients are 5% of childhood-onset dystrophin-normal muscular dystrophy and most partial deficiency patients do not have gene mutations." Journal of the Neurological Sciences **140**(1-2): 30.

<http://www.sciencedirect.com/science/article/B6T06-3YTCC1P-4/2/38550f3840bd3842055d95e640353c40>

[alpha]-Sarcoglycan (adhalin), a 50-kDa component of the dystrophin-associated complex of proteins, participates in the stabilization of the myofiber plasma membrane in the membrane cytoskeleton. Deficiencies of [alpha]-sarcoglycan cause a subset of childhood-onset muscular dystrophy (SCARMD) cases. However, secondary deficiencies of [alpha]-sarcoglycan are common. To begin to establish the rates of false positives (secondary deficiencies), we used immunofluorescence to screen 30 Italian dystrophin-normal muscular dystrophy patient biopsies and identified 4 patients with partial [alpha]-sarcoglycan deficiency and 2 patients with complete deficiency. The entire [alpha]-sarcoglycan gene was screened for mutations using RT-PCR and

SSCP of messenger RNA isolated from muscle biopsies in each of the six patients. Aberrant SSCP conformers and novel mutations were found only in the two complete immunohistochemical deficient patients. One patient was homozygous for a R34H amino acid substitution, while the other was a compound heterozygote (R77C, D97G). These three missense mutations, with additional mutations we and others have previously described, are all localized in the extracellular domain of [alpha]-sarcoglycan, and most result in the loss or gain of a positively charged amino acid. These data have strong implications for structure/function maps of the [alpha]-sarcoglycan molecule. Our results suggest that most patients showing partial [alpha]-sarcoglycan deficiency exhibit this as a secondary consequence of genetically distinct disorders. In support of this, we show biochemical data indicating that secondary deficiency patients show decreased immunostaining with antibodies directed against [alpha]-sarcoglycan, while having nearly normal quantities of [alpha]-sarcoglycan protein on immunoblot. This data also suggests that approximately 5% of childhood-onset dystrophin-normal muscular dystrophy patients will show a primary [alpha]-sarcoglycan deficiency.

Fassati, A., A. Bordoni, et al. (1994). "Chronic progressive external ophthalmoplegia: A correlative study of quantitative molecular data and histochemical and biochemical profile." Journal of the Neurological Sciences **123**(1-2): 140.

<http://www.sciencedirect.com/science/article/B6T06-485RNVW-7/2/7033a3d584fd925e05dcddcde4595a13>

We studied muscle biopsies of 5 patients with Kearns-Sayre syndrome and 3 patients with chronic progressive external ophthalmoplegia all with the common deletion. Steady state levels of normal and deleted mitochondrial DNA (mtDNA) measured in each patient by quantitative PCR were correlated with histochemical and biochemical features. We found that (1) normal mtDNA levels were higher in many patients than in controls; (2) as levels of deleted mtDNA increased, so did levels of normal mtDNA; (3) cytochrome c oxidase (COX) activity and the percentage of COX negative fibers were both related to the levels of deleted mtDNA; and (4) as percentage of ragged red fibers increased, so did levels of total, deleted and normal mtDNA. The quantity of deleted mtDNA plays a key role in determining the severity of COX deficiency, which is responsible for the overaccumulation of mitochondria in muscle.

Fukazawa, T., I. Yabe, et al. (1999). "Association of vitamin D receptor gene polymorphism with multiple sclerosis in Japanese." Journal of the Neurological Sciences **166**(1): 47.

<http://www.sciencedirect.com/science/article/B6T06-3X10TCY-7/2/2c595165166f4fea2acc70b93dd916be>

1,25-Dihydroxyvitamin D3 (1,25(OH)2D3), the biologically active form of vitamin D, exerts an immunosuppressive effect and can completely prevent experimental autoimmune encephalomyelitis (EAE). 1,25(OH)2D3 exerts most of its actions only after it has bound to its specific nuclear receptors. To investigate the possible role of vitamin D receptor gene (VDRG) polymorphism in susceptibility to or disease-modulation of MS, we evaluated 77 Japanese patients with 'conventional' MS and 95 controls. A VDRG allelic polymorphism was assessed by Bsm1 endonuclease restriction after specific PCR amplification. Genotypic polymorphism was clearly defined as BB (absence of restriction site on both alleles), bb (presence of restriction site on both alleles), or Bb (heterozygous). We found overexpression of the b allele (92.9 vs. 84.2%; $P=0.0138$) and homozygote bb (85.7 vs. 71.6%; $P=0.0263$) in MS patients compared with controls. The results indicate for the first time an association of MS with VDRG polymorphism, which may be involved in pathogenesis of MS, or in the linkage disequilibrium of VDRG to another pathogenic gene loci. The role of VDR gene polymorphism should be further studied in

other populations, and the distribution of other polymorphism, such as Apa I, Taq I, should be also analyzed to confirm another susceptibility gene for MS and to obtain more adequate strategies for treatment of MS.

Harness, J., M. P. Pender, et al. (2001). "Cyclosporin A treatment modulates cytokine mRNA expression by inflammatory cells extracted from the spinal cord of rats with experimental autoimmune encephalomyelitis induced by inoculation with myelin basic protein." Journal of the Neurological Sciences **187**(1-2): 7.

<http://www.sciencedirect.com/science/article/B6T06-43CR9GC-2/2/1b7add39f08243a6a9732a5852225d8f>

In Lewis rats, treatment with high doses of cyclosporin A (CsA) suppresses clinical signs of experimental autoimmune encephalomyelitis (EAE), although disease occurs when treatment is ceased. Treatment with low doses of CsA causes EAE to take a chronic relapsing course. We have previously shown that CsA treatment causes a decline in the number of T cells and increased inflammatory cell apoptosis in the spinal cord. The present study was undertaken to assess whether CsA therapy also modulates cytokine mRNA expression by inflammatory cells in the spinal cord of rats with EAE, looking for changes that might contribute to the observed effects of CsA on the course of EAE. EAE was induced in Lewis rats by inoculation with myelin basic protein and adjuvants. At the peak of neurological signs, on day 14 after inoculation, rats were given a single intraperitoneal injection of saline, or CsA at a dose of 8, 16, 32 or 64 mg/kg. The next day, rats were sacrificed, the spinal cords removed, inflammatory cells were extracted from the cords, and mRNA isolated from these cells. Expression of cytokine mRNA was assessed by semi-quantitative reverse transcription polymerase chain reaction (PCR) and by quantitative real-time PCR. With both techniques, we found that CsA suppressed the expression of interferon- γ mRNA and interleukin-2 (IL-2) mRNA. With real-time PCR, we found that CsA caused significantly increased expression of transforming growth factor- β mRNA. With the different techniques, we observed no consistent pattern of alteration of expression of interleukin-10 or interleukin-4 mRNA. It is possible that these changes in cytokine mRNA expression contribute to the modulation of the clinical course of EAE that is produced by CsA treatment.

Hug, A., B. Storch-Hagenlocher, et al. (2004). "Single-cell PCR analysis of the immunoglobulin heavy-chain CDR3 region for the diagnosis of leptomeningeal involvement of B-cell malignancies using standard cerebrospinal fluid cytopspins." Journal of the Neurological Sciences **219**(1-2): 83.

<http://www.sciencedirect.com/science/article/B6T06-4BNW2TD-1/2/4438339b85de92037ec1fcd25c6c6f83>

The diagnosis of leptomeningeal B-cell malignancies is based on the identification of malignant B cells in the cerebrospinal fluid (CSF). We have established a polymerase chain reaction (PCR) approach to characterize the clonally diverse gene encoding the immunoglobulin heavy-chain (IgH) third complementarity determining region (CDR3) of single B cells. We demonstrate that single-cell PCR is readily applicable to individual cells derived from routine CSF cytopspins and is a powerful method to discriminate monoclonal neoplastic from polyclonal reactive B-cell responses. Single-cell PCR analysis, as a new tool for the diagnosis and monitoring of neoplastic meningitis associated with B-cell malignancies, is particularly important if cytology, immunocytochemistry, flow cytometry and automated gene scanning of CSF samples are unable to detect malignant monoclonal proliferation.

Kobayashi, T., H. Matsumine, et al. (2003). "Pseudo-autosomal dominant inheritance of PARK2: two families with parkin gene mutations." Journal of the Neurological Sciences **207**(1-2): 11.

<http://www.sciencedirect.com/science/article/B6T06-479TPP1-2/2/5cba44b49a15d7f339976294cf93b95e>

We report two families (Family S and Family N) with early-onset parkinsonism in two generations. The mode of inheritance appeared to be autosomal dominant, however, haplotype analysis suggested linkage to chromosome 6q25.2-27, the PARK2 locus, and all affected members were homozygotes in their haplotypes. In Family S, the affected father was married to unaffected mother, who carried one disease-linked haplotype at chromosome 6q25.2-27. In Family N, the unaffected mother carried one disease-linked haplotype. Quantitative PCR amplification analysis revealed exon 3 deletion in Family S and exon 5 deletion in Family N. The age of onset was from 18 to 22 years in Family S and 25 to 42 years in Family N. In both of their hometowns, most people lived in the same districts for many generations and consanguineous marriages had been common. Thus, the carrier state of the parkin gene might have been high in those communities, and marriage of a patient and a carrier is expected to result in autosomal dominant like inheritance. We conclude that PARK2 cannot be excluded even if the mode of inheritance appears as autosomal dominant, when the affected patients are young.

Lynas, C., T. J. Hill, et al. (1993). "Latent infection with the MS strain of herpes simplex virus type 2 in the mouse following intracerebral inoculation." Journal of the Neurological Sciences **120**(1): 107.

<http://www.sciencedirect.com/science/article/B6T06-485YBS7-4H/2/33c529bf1656ccc8d74e47195248a841>

Intracerebral inoculation of the MS strain of herpes simplex virus type 2 (HSV-2) into mice causes an acute encephalitis associated with multifocal demyelination and necrotizing retinitis. We have studied the distribution of latent virus in mice that had recovered from the acute encephalitis. Four weeks or longer after inoculation, HSV-2 could be recovered from the trigeminal ganglia of all mice examined by co-culture of explants in roller tubes. The virus could not be recovered from explants of retina or brain stem. HSV-2 latency associated transcript (LAT) was readily detected in the trigeminal ganglia by reverse transcriptase-PCR more than 4 months after inoculation. LAT was also demonstrated in the brain but this required nested PCR for consistent detection. Both LAT and ICP0 mRNA were detected in brain tissue during the acute encephalitis but, unlike LAT, ICP0 mRNA could not be amplified from the trigeminal ganglia or brain beyond 4 weeks after inoculation of the virus. In situ hybridisation with a double-stranded DNA probe to the ICP0/LAT overlap region of HSV-2 revealed signal in trigeminal ganglion neurons and occasional cells in the brain stem. These findings indicate that HSV-2 introduced by intracerebral inoculation becomes latent in the trigeminal ganglia and that transcription of LAT also persists within the brain.

McDonnell, G. V., C. W. Kirk, et al. (2000). "An evaluation of interleukin genes fails to identify clear susceptibility loci for multiple sclerosis." Journal of the Neurological Sciences **176**(1): 4.

<http://www.sciencedirect.com/science/article/B6T06-40J1D85-2/2/ffc60ab7a79e967f2264640a94460aa7>

Differential expression of interleukins may influence susceptibility to inflammatory diseases such as MS. IL-1a production is increased in MS patients during acute relapse, IL-2 receptor (IL-2R) secretion correlates with disease activity in several inflammatory disorders and is variable in MS.

Both IL-4 and IL-10 expression vary significantly with relapse/remission in MS and IL-9 is postulated to inhibit steroid-induced apoptosis. To examine the influence of interleukin (IL) genes on MS susceptibility and clinical course, gene association studies using separate polymorphic microsatellite markers for il-1[alpha], il-2, il-2r[beta], il-4 il-9 and il-10 were performed, incorporating 150-177 relapsing-remitting or secondary progressive MS (RR/SPMS) patients, 100-110 primary progressive (PPMS) patients and 152-210 controls. No significant differences existed in allele frequencies between either MS group and controls for any of the interleukin microsatellite markers studied, nor were statistically significant differences observed in PPMS vs. RR/SPMS for any marker. These data indicate that the IL-1[alpha], IL-2, IL-2R[beta], IL-4, IL-9 and IL-10 genes are unlikely to be susceptibility loci for MS in this population.

Melberg, A., J. Hetta, et al. (1995). "Autosomal dominant cerebellar ataxia deafness and narcolepsy." Journal of the Neurological Sciences **134**(1-2): 119.

<http://www.sciencedirect.com/science/article/B6T06-3Y45GTF-1P/2/9e2ed4a9dbd407008752363536cd6526>

A new autosomal dominant syndrome in a Swedish pedigree is described. Five patients were affected with cerebellar ataxia and sensorineural deafness. Four of these patients had symptoms of narcolepsy. Optic atrophy, other neurological abnormalities and psychiatric symptoms developed with increasing disease duration. Three patients had non-neurological disease in addition, including diabetes mellitus in two and hypertrophic cardiomyopathy in one. Autopsy with neuropathological examination was performed in one case. Molecular studies focused on the short arm of chromosome 6, including the HLA DR2 locus associated with narcolepsy and the (CAG)_n repeat at the spinocerebellar ataxia type 1 (SCA1) locus. Biochemical investigation of muscle biopsy of one case indicated mitochondrial dysfunction with selective decrease in ATP production for substrates that normally give the highest rates. The activity of glutamate dehydrogenase was reduced, indicating a low mitochondrial density. We postulate an autosomal dominant genetic factor responsible for this syndrome. Linkage was excluded to HLA DR2, and a normal sized SCA1 repeat was observed. We conclude that a locus predisposing to ataxia, deafness and narcolepsy exists outside this region of chromosome 6.

Niemann, C. U., T. O. B. Krag, et al. (2000). "Identification of genes that are differentially expressed in extraocular and limb muscle." Journal of the Neurological Sciences **179**(1-2): 76.

<http://www.sciencedirect.com/science/article/B6T06-41H3KMT-8/2/fd583026a595a4779dbdc02aa532615a>

The extraocular muscles (EOM) are anatomically and physiologically distinct from other striated muscles in mammals. Among other differences, they can be driven to generate individual twitch contractions at an extremely high frequency and are resistant to [Ca²⁺]-induced myonecrosis. While EOM are preferentially targeted in some neuromuscular diseases such as myasthenia gravis and congenital fibrosis of the extraocular muscles, they are enigmatically spared in Duchenne's muscular dystrophy, despite the widespread damage seen in all other skeletal muscle groups during the course of this disease. To address the molecular mechanisms that specify the EOM-phenotype, we characterized the transcriptional profile of genes expressed in rat EOM versus limb muscle using a differential display strategy. Ninety-five putative differentially expressed cDNA tags were cloned, from which fourteen were confirmed as being differentially expressed by RNA slot blot and Northern blot analysis. Ten of these cDNAs were homologous to known human or murine genes and ESTs, while four genes that were upregulated in EOM were novel, and have been named expressed in ocular muscle (eom) 1-4. The identification of these differentially expressed genes may provide mechanistic clues toward understanding the unique

patho-physiological phenotype of EOM.

Niino, M., T. Fukazawa, et al. (2000). "Vitamin D receptor gene polymorphism in multiple sclerosis and the association with HLA class II alleles." Journal of the Neurological Sciences **177**(1): 65.

<http://www.sciencedirect.com/science/article/B6T06-4123D0R-8/2/285f1c4bd70f82e21ed26ba3c02c2c08>

We have previously reported that the association between Bsm I polymorphism, one of the vitamin D receptor genes (VDRG) polymorphism, and multiple sclerosis (MS). In this report, we investigated the further possible role or relevance of VDRG in the pathogenesis of MS. Apa I polymorphism was detected by PCR-RFLP from the DNA of 77 conventional MS patients and 95 healthy controls. The study of the Bsm I and Apa I haplotypes was carried out by employing previously reported Bsm I data. The AA genotype and the [A] allele in the profiles were significantly more prevalent in MS patients than in controls ($P=0.0070$ and $P=0.0321$, respectively). In the [A] allele-positive MS patients, the positive rate of DPB1*0501 in HLA was significantly higher than that of the [A] allele-positive controls and that of the [A] allele-negative MS patients even when the corrected P value (Pcorr) was applied ($P_{\text{corr}}=0.0220$ and $P_{\text{corr}}=0.0077$, respectively). The frequency of DRB1*1501 was higher in the [A] allele-positive patients than in the [A] allele-positive controls and the [A] allele-negative patients ($P_{\text{uncorr}}=0.0431$ and $P_{\text{uncorr}}=0.0089$, respectively), but the P values did not reach statistical significance after P corrections. The rate of Bsm I and Apa I haplotypes was much higher in bA/bA-positive MS patients than in the controls ($P=0.0003$), and in the bA positive MS patients, the positive rate of DPB1*0501 was higher than that of the bA-positive controls and that of the bA-negative MS patients ($P_{\text{corr}}=0.0308$ and $P_{\text{corr}}=0.0033$, respectively). These results indicate that VDRG polymorphism may be associated with susceptibility to MS, and HLA alleles may correlate with risk for MS together with VDRG.

Niino, M., S. Kikuchi, et al. (2000). "Estrogen receptor gene polymorphism in Japanese patients with multiple sclerosis." Journal of the Neurological Sciences **179**(1-2): 70.

<http://www.sciencedirect.com/science/article/B6T06-41H3KMT-7/2/648b50c613b61e5a8fe7c092ca82ccce>

Estrogen has been reported to have immunosuppressive functions, and to inhibit the progression of experimental autoimmune encephalomyelitis (EAE), an animal model of multiple sclerosis (MS). Since estrogen shows its biological effects via estrogen receptors (ER), we investigate the possible role of ER genes (ERG) in the pathogenesis of MS. PvuII and XbaI polymorphisms in ERG were detected by PCR-RFLP from the DNA of 79 conventional MS patients and 73 healthy controls. The [P] allele in the profiles in PvuII was significantly more prevalent in MS patients than in the controls (PXBal polymorphism, the onset age of MS patients with the Xx genotype was earlier than that of the xx genotype group (mean age $\pm$ S.D.; 22.60 ± 8.04 , and 27.49 ± 9.14 , respectively) (PPvuII polymorphism might be associated with susceptibility to MS, and XbaI polymorphism with onset age of MS. ERG polymorphism should be further studied in other populations to improve strategies for treatment of MS.

Nishimura, M., M. Nukina, et al. (1997). "Characterization of Campylobacter jejuni isolates from patients with Guillain-Barre syndrome." Journal of the Neurological Sciences **153**(1): 91.

<http://www.sciencedirect.com/science/article/B6T06-3RSFG7M-J/2/82ea6508ac9ff892a8ead3d3b6706506>

Campylobacter jejuni is a major pathogen preceding Guillain-Barre syndrome (GBS), and most *C. jejuni* isolates from GBS patients belong to Penner serotype 19 (heat-stable; HS-19). We analyzed sixteen independent clinical isolates from GBS patients, twelve of which belonged to HS-19, three to HS-2, and one to HS-4, using PCR-based RFLP analysis of a flagellin-A (*flaA*) gene. Two isolates from patients with Miller Fisher syndrome (MFS), and 27 from patients with uncomplicated enteritis were also examined. All HS-19 isolates, regardless of GBS, showed an identical pattern (Cj-1) by RFLP typing and were distinguishable from those of the other Penner serogroups. In contrast, HS-2 and HS-4 isolates were divided into several different RFLP groups, suggesting HS-19 strains are genetically distinctive among *C. jejuni* isolates. A DNA fingerprinting method also failed to detect any specific band pattern for GBS-related *C. jejuni* isolates. We examined relationships among anti-GM1 antibody titres in the sera of GBS patients, clinical forms of GBS, serotype of *C. jejuni*, and the presence of GM1-like structures in lipopolysaccharide (LPS) components from *C. jejuni* isolates by immunoblotting. HS-19 related GBS was significantly associated with elevated anti-GM1 antibody titers in the sera of the patients, but not associated with any clinical pattern of GBS. No significant correlations were found between anti-GM1 antibody and the pattern of disease, or between GBS-related *C. jejuni* strains and the presence of GM1-like structures. HS-19 strains seem to be unique among *C. jejuni* isolates, and HS-19-related GBS may provide an excellent model for clarification of the pathogenesis of GBS.

Sambuughin, N., K. Sivakumar, et al. (1998). "Autosomal dominant distal spinal muscular atrophy type V (dSMA-V) and Charcot-Marie-Tooth disease type 2D (CMT2D) segregate within a single large kindred and map to a refined region on chromosome 7p15." Journal of the Neurological Sciences **161**(1): 23.

<http://www.sciencedirect.com/science/article/B6T06-3V8RP1X-5/2/2bd80fb0c03d8751c1079b0740ffea5>

Two separate disorders, autosomal dominant distal spinal muscular atrophy type V (dSMA-V) characterized by marked bilateral weakness in the hands and atrophy of thenar eminence and the first interosseous muscle, and Charcot-Marie-Tooth disease type 2D (CMT2D) characterized by sensory deficits in addition to the upper limb weakness and wasting, have been independently linked to chromosome 7p. We identified a multigenerational Mongolian kindred with 17 members affected with either dSMA-V or CMT2D and mapped both syndromes to the same region on chromosome 7p15. A maximum two-point lod score of 4.74 at recombination fraction zero was obtained with marker D7S474. Tight linkage without recombination was also detected with markers D7S526 and D7S632. A multipoint lod score of 6.07 suggested that the gene is located between markers D7S526 and D7S474. A single conserved haplotype was associated with dSMA-V and CMT2D. Based on informative recombination events, the disease locus was placed between markers D7S516 and D7S1514 within the 7p15 band. Data obtained from this study suggest that a single gene is responsible for both syndromes, dSMA-V and CMT2D, and extend our knowledge of the candidate region.

Shiraiwa, N., A. Ishii, et al. (1993). "Content of mutant mitochondrial DNA and organ dysfunction in a patient with a MELAS subgroup of mitochondrial encephalomyopathies." Journal of the Neurological Sciences **120**(2): 174.

<http://www.sciencedirect.com/science/article/B6T06-485RJ8W-MC/2/38ada2a4cb28fd15715680811ba8edd0>

A point mutation of mitochondrial tRNA^{Leu}(UUR) gene is responsible for a MELAS (mitochondrial myopathy, encephalopathy, lactic acidosis and stroke-like episodes) subgroup of mitochondrial encephalomyopathies. In most cases, the mutant mitochondrial DNA (mtDNA) coexists with normal mtDNA in a heteroplasmic manner. In order to quantify the content of mutant mtDNA, we developed a quantitative method of PCR. Using this method, the distribution of the mutant mtDNA was examined in 32 different tissues among 18 autopsied organs from a patient with MELAS, who had shown hypophyseal dysfunction. The percentage of the mutant mtDNA at nucleotide number 3243 in each tissue was ranged between 22% and 95%. The content of the mutant mtDNA was at the highest (95%) in the hypophysis and higher in the cerebral cortex than in the white matter. This study shows a possible correlation of tissue dysfunction with accumulation of the mutant mtDNA within the brain.

Wagnerova, J., L. Cervenakova, et al. (2002). "Cytokine regulation of E-selectin in rat CNS microvascular endothelial cells: differential response of CNS and non-CNS vessels." Journal of the Neurological Sciences **195**(1): 51.

<http://www.sciencedirect.com/science/article/B6T06-44VX674-1/2/685e416f20487d3ca4adf3e5190ffaa5>

We have compared the induced expression of E-selectin in primary cultures of rat brain microvascular endothelial cells (EC), pericytes and in non-CNS microvascular endothelium stimulated with the cytokines, IL-1[β] (20 ng/ml), and tumor necrosis factor (TNF)-[α] (75 ng/ml). Expression was studied at both the protein and mRNA levels. Fluorescence in-situ hybridization (FISH) was used to examine de novo synthesis of E-selectin mRNA. Laser cytometric analysis was used as a novel approach to the quantitation of FISH. In-situ hybridization was performed using two PCR-generated probes. The first probe (517 bp) spanned the lectin and epidermal growth factor (EGF)-like domain. The second probe (562 bp) spanned the CR3, 4, and 6 domains. E-selectin-specific mRNA was localized to the perinuclear regions of the EC. Both cytokines, IL-1[β] and TNF-[α] significantly increased E-selectin gene expression in CNS EC but not pericytes. IL-1[β] induced higher E-selectin mRNA levels than TNF-[α]. The maximum number of mRNA-positive cells was observed after stimulation for 4-6 h. Surface protein expression was sustained for up to 48 h following addition of cytokine. This was in contrast to the transient expression in non-CNS EC indicating that pure primary CNS EC display slightly different kinetics of E-selectin expression than non-CNS EC.

Yamada, T., A. Kondo, et al. (1995). "Apolipoprotein E mRNA in the brains of patients with Alzheimer's disease." Journal of the Neurological Sciences **129**(1): 56.

<http://www.sciencedirect.com/science/article/B6T06-3Y44T67-2F/2/7252236fd37878b433758be2d7ad9aa6>

To clarify the role of apolipoprotein E (apoE) in the pathophysiology of Alzheimer's disease (AD), we used an RT-PCR method to investigate apoE and glial fibrillary acidic protein (GFAP) mRNA expression in the brain. ApoE mRNA was significantly more abundant in AD (0.379 $\pm$ 0.191, mean $\pm$ SD) than in control (0.125 $\pm$ 0.073, $p < 0.05$) brain tissue, but in AD it was decreased in relation to the apoE-[ϵ]4 gene dosage. The GFAP mRNA content also was greater in AD (5.96 $\pm$ 2.94) than in control (3.80 $\pm$ 2.78) tissue, and in AD showed an increase relative to the apoE-[ϵ]4 gene dosage. AD patients who had long survival times showed high expression of apoE and low expression of GFAP. These results suggest that apoE suppresses the progression of AD, including gliosis, in the brain.

Yamashita, T., Y. Ando, et al. (2000). "A new diagnostic procedure to detect unknown transthyretin (TTR) mutations in familial amyloidotic polyneuropathy (FAP)." Journal of the Neurological Sciences **173**(2): 154.

<http://www.sciencedirect.com/science/article/B6T06-3YJ9XM5-D/2/35877d454693bebedbf5770d7ee0d13b>

Two patients with amyloidosis caused by transthyretin (TTR) were investigated by immunohistopathologic, mass spectrometric, and molecular genetic methods. After confirming the immunoreactivity of TTR in the amyloid deposits using anti-TTR polyclonal antibody, a new method: centrifugal concentration and electrospray ionization mass spectrometry (ESI-MS) was employed to detect the variant TTR in the serum. Only 50 [μl] of the serum and 30 [μl] of the anti-TTR antibody were needed for the analysis. After incubation with the antibody, the samples were passed through a 1000 kDa cut off centrifugal concentrator to retain the antibody, thereafter, the filtrate was analyzed by ESI-MS. Several forms of normal and variant TTR were detected in the serum samples: unconjugated TTR, cysteine and cysteine-glycine conjugated TTR. In the patients, a variant form of TTR was detected with a 26.0 Da higher molecular weight than that of normal TTR. Single-strand conformation polymorphism (SSCP) and direct sequence analysis confirmed the presence of a one-base substitution situated at the codon 50 from AGT (Ser) to ATT (Ile) in both patients, that corresponded to the increased molecular weight of 26.0. The present diagnostic procedure demonstrates the usefulness of both ESI-MS and SSCP to screen for TTR related amyloidosis rapidly. Moreover, the DNA samples obtained from the band showing abnormal electrophoretic migration pattern in SSCP, facilitate the direct sequence analysis to detect the unknown mutation, and the observed shift in molecular weight of the variant TTR in ESI-MS confirms the base substitution.

Yoshihara, T., F. Kanda, et al. (2001). "A novel missense mutation in the early growth response 2 gene associated with late-onset Charcot-Marie-Tooth disease type 1." Journal of the Neurological Sciences **184**(2): 149.

<http://www.sciencedirect.com/science/article/B6T06-42G0KYK-6/2/5505caba443481a5212146478e88258d>

A novel mutation (Arg381Cys) in the second zinc-finger domain of early growth response 2 (EGR2) was identified in a late-onset Charcot-Marie-Tooth disease type 1 (CMT1) patient. This patient had initial symptoms of numbness and weakness in the leg at age 59, and a median nerve motor conduction velocity of 27 m/s. A sural nerve biopsy showed a severe loss of myelinated fibers with numerous onion bulbs. This is the first report of the EGR2 mutation presenting a late onset of CMT1 phenotype. Its mutation was a different amino acid substitution at codon 381 (Arg381His) which demonstrated congenital hypomyelinating neuropathy or early-onset CMT1. This report suggests that the EGR2 mutation represents divergent phenotypes at codon 381, which may be a mutation hotspot.

Zhai, Q.-H., N. Futrell, et al. (1997). "Gene expression of IL-10 in relationship to TNF-[α], IL-1[β] and IL-2 in the rat brain following middle cerebral artery occlusion." Journal of the Neurological Sciences **152**(2): 119.

<http://www.sciencedirect.com/science/article/B6T06-3RH634P-1/2/eee9e17eb503cd360f95eb8a3ec0fce2>

To systematically elucidate the gene expression of inflammatory and immune modulators following middle cerebral artery occlusion (MCAO) in the rat, we studied interleukin-10 (IL-10) along with tumor necrosis factor alpha (TNF-[alpha]), interleukin-1 beta (IL-1[beta]) and interleukin-2 (IL-2). Gene expression of these cytokines was studied ipsilateral and contralateral to the MCAO, with mRNA expression levels evaluated 2, 4, 6, 8 and 12 h following permanent MCAO by reverse transcriptase polymerase chain reaction (RT-PCR). In the ischemic hemisphere TNF-[alpha] and IL-1[beta] mRNA increased at 2 h following MCAO and peaked at 6 h, with IL-10 mRNA detected only at 6 h. Contralaterally, both TNF-[alpha] and IL-1[beta] mRNAs were expressed with a similar pattern to that in the ischemic hemisphere, but at lower levels, with no contralateral IL-10 expression. There was no difference in IL-2 gene expression between control and experimental animals in either hemisphere. These results demonstrate that IL-10 and TNF-[alpha], IL-1[beta] gene expression is induced early following MCAO. The temporal profile of these cytokines is similar to that seen in sepsis, where TNF-[alpha] induces IL-10; subsequently IL-10 inhibits TNF-[alpha] expression. The similarity of the temporal profile of cytokine expression in sepsis and cerebral ischemia suggests that IL-10 should be studied as a potential inhibitor of TNF-[alpha] production in ischemic brain tissue. The factors inducing contralateral expression of the inflammatory cytokines, TNF-[alpha] and IL-1[beta], along with the potential clinical significance of this remote cytokine gene expression, merit further study.

Journal of the Society for Gynecologic Investigation (10)

Chen, Z., W. Huang, et al. (2004). "Serine racemase and -serine transport in human placenta and evidence for a transplacental gradient for -serine in humans." Journal of the Society for Gynecologic Investigation **11**(5): 294.

<http://www.sciencedirect.com/science/article/B6T93-4CPJM90-6/2/b0a11eb5a1e58a7206ddd100dcf98624>

ObjectiveTo investigate the possible role of human placenta in providing -serine to the developing fetus.
MethodsExpression of serine racemase in placenta was determined by reverse transcriptase polymerase chain reaction and northern analysis and confirmed by subsequent cloning. The transport of -serine by human ATB0 was characterized by expressing the cloned cDNA transiently in mammalian cells using the vaccinia virus expression system. -serine levels in maternal and fetal blood were measured by fluorescence high-performance liquid chromatography (HPLC) after derivatization of the amino acids with o-phthaldialdehyde and N-tertiary-butyloxycarbonyl--cysteine.
ResultsmRNA for serine racemase was detected in placenta. ATB0 was capable of -serine transport, and the transport process is obligatorily dependent on sodium (Na⁺) with a Na⁺:substrate stoichiometry of 1:1 and saturable with a Michaelis-Menten constant of 310 +/- 30 [mu]M. Furthermore, studies have shown that ATB0 is not expressed in the maternal-facing brush border membrane of human placental syncytiotrophoblast. The circulating concentration of -serine in maternal serum is 5.8 +/- 0.5 [mu]M, and the corresponding value in the fetal serum is 14.6 +/- 1.2 [mu]M, indicating a two- to three-fold higher concentration of -serine in the fetus than in the mother.
ConclusionWe speculate that -serine is synthesized in human placenta by the racemization of -serine and that ATB0, expressed on the basal membrane of the syncytiotrophoblast, mediates the efflux of -serine into the fetal circulation in exchange for other amino acids in fetal blood.

Cheung, C. Y. and R. A. Brace (1999). "Developmental expression of vascular endothelial growth factor and its receptors in ovine placenta and fetal membranes." Journal of the Society for Gynecologic Investigation **6**(4): 179.

<http://www.sciencedirect.com/science/article/B6T93-3X9RY8X-3/2/b26a90041d2507854d0895b91500ada8>

Objectives: Vascularity of the surface of the placenta in humans and of the placenta and fetal membranes in several species including sheep is an important determinant of intramembranous absorption of amniotic fluid. Our previous studies have shown that the total blood vessel surface area in ovine amnion and chorion increases with advancing gestation. Vascular endothelial growth factor (VEGF) is a potent angiogenic and permeability factor and is found to be expressed in the ovine placenta and fetal membranes. To investigate the role of VEGF in maintaining the absorptive function of the intramembranous microvessels, the present study was undertaken to determine the gestational change in gene expression of VEGF and its receptors, kinase insert domain-containing receptor (KDR) and fms-like tyrosine kinase (Flt-1), in ovine placenta, chorion, and amnion. **Methods:** Total RNA was extracted from placental cotyledon, chorion, and amnion of ovine fetuses at 60-140 days of gestation. The relative abundance of VEGF, KDR, and Flt-1 mRNA was determined by Northern blot analysis, and VEGF molecular forms expressed were identified by reverse transcriptase polymerase chain reaction. The gestational changes in mRNA levels of VEGF and its receptors were analyzed by regression analysis. **Results:** In ovine placenta, chorion, and amnion, VEGF mRNA levels increased significantly from 60 to 140 days. The major VEGF molecular form expressed in these tissues was VEGF₁₆₄, whereas VEGF₁₂₀, VEGF₁₄₄, and VEGF₁₈₈ were present at lower levels. In the placenta, KDR was the primary VEGF receptor expressed, although Flt-1 was also detected at very low levels. In the amnion and chorion, KDR was the only receptor expressed. A gestational-dependent change in VEGF receptor expression was not observed in the placenta and membranes. **Conclusions:** The increase in VEGF gene expression with advancing gestation in the amnion and chorion where KDR is expressed suggests that VEGF and its receptor are important determinants of vascularity and permeability, and thus exchange capacity, of the intramembranous pathway.

Chien, E. K., L. Sweet, et al. (2003). "Protease-activated receptor isoform expression in pregnant and nonpregnant rat myometrial tissue." Journal of the Society for Gynecologic Investigation **10**(8): 460.

<http://www.sciencedirect.com/science/article/B6T93-4B4NYRR-3/2/820a6f54409d49e7b1347ee364c8f544>

Objective Three protease-activated receptor (PAR1, 3, and 4) isoforms have been shown to be responsible for the cellular effects of thrombin; another PAR isoform (PAR2) is responsible for the cellular effects of trypsin. The present studies sought to test the hypothesis that one (or more) of these PAR isoforms is expressed in myometrial tissue, thereby accounting for the uterotonic effects of these novel agonists. **Methods** The rat PAR3 and 4 isoforms were cloned from a rat spleen cDNA library. PAR isoform mRNA expression was determined by using reverse-transcriptase polymerase chain reactions (PCR) in Sprague-Dawley rats. Confirmation of the identity of the amplified mRNA was done by sequence analysis. Relative quantification of the PAR1 and PAR2 isoforms was performed using a real-time quantitative reverse transcriptase PCR (RT-PCR) technique. PAR protein expression was confirmed by Western blots using polyclonal antibodies. **Results** The rat PAR3 and 4 homologues showed significant sequence homology to the mouse and human amino acid and nucleotide sequences. The RT-PCR studies confirmed PAR1-4 expression in myometrium from rats in estrus. PAR3 was expressed in uterus, spleen, kidney, liver, lung, brain, and heart. PAR4 was expressed in uterus, spleen, and lung. Messenger RNA for the PAR1 and 2 isoforms was expressed during the second half of gestation in myometrium from timed-pregnant rats. In contrast, mRNA for the PAR3 and 4 isoforms was not

detected in gestational myometrium. PAR protein expression appeared to match tissue mRNA expression patterns. Conclusion These RT-PCR studies confirmed ubiquitous expression of the PAR1 and PAR2 isoforms in myometrium and other rat tissues; in contrast, the PAR3 and PAR4 isoforms are expressed in a tissue-specific and gestationally related pattern.

Emmer, P. M., I. Joosten, et al. (2004). "Shift in expression of HLA-G mRNA spliceforms in pregnancies complicated by preeclampsia." Journal of the Society for Gynecologic Investigation **11**(4): 220.

<http://www.sciencedirect.com/science/article/B6T93-4C8FJYB-5/2/a9660fe2ca4d608703128845a53ee9bf>

Objective Despite emerging data on the in vitro modulatory effects of trophoblast-associated human leukocyte antigen G (HLA-G), its in vivo function needs to be determined. Immunohistochemical studies show a decrease in protein expression of trophoblast HLA-G in preeclampsia. Such a decrease in protein might be the consequence of a shift in HLA-G mRNA spliceform patterns. In an exploratory pilot study we determined trophoblast HLA-G mRNA spliceform distribution in preeclampsia. Methods Placental samples were collected immediately after cesarean delivery from pregnancies complicated by preeclampsia or the syndrome hemolysis, elevated liver enzymes, and low platelet count (HELLP) and uncomplicated normotensive pregnancies as controls. HLA-G mRNA spliceform distribution was analyzed using a semiquantitative reverse transcriptase polymerase chain reaction procedure. Results Analysis of HLA-G spliceform distribution showed a significant increase in frequency of the G5 form encoding for a soluble HLA-G molecule in preeclampsia. This increase in G5 form was not found in pregnancies complicated by HELLP. Conclusion The increased frequency in the expression of the HLA-G G5 spliceform may play a role in the pathophysiology of preeclampsia, in particular through a recently suggested effect of this soluble HLA-G molecule on remodeling of the spiral arteries.

Havrilesky, L. J., C. P. McMahon, et al. (2001). "Relationship between expression of coactivators and corepressors of hormone receptors and resistance of ovarian cancers to growth regulation by steroid hormones." Journal of the Society for Gynecologic Investigation **8**(2): 104.

<http://www.sciencedirect.com/science/article/B6T93-42XB4KM-8/2/765a065315245fd5e8cf50b3d38073e9>

Objective: To determine whether aberrant expression of hormone receptor corepressors or coactivators or defects in estrogen receptor-mediated transcription might underlie resistance of ovarian cancers to hormonal therapy. Methods: Northern analysis, Western analysis, and polymerase chain reaction were used to examine expression of estrogen receptor (ER), progesterone receptor (PR), the nuclear receptor corepressors N-CoR and SMRT, and the steroid receptor coactivator BRG-1 in ovarian cancer cell lines and primary cancers. The effect of BRG-1 transfection on ER-mediated transcription was examined. We also determined the effect of estrogen and the pure estrogen antagonist ICI 182,780 on cell cycle profile and expression of ER. Finally, we examined the ability of estrogen to upregulate expression of known estrogen-responsive genes. Results: Among primary ovarian cancers, 18 of 52 (35%) expressed N-CoR, and 37 of 52 (71%) expressed SMRT, but there was no correlation between expression of corepressors and hormone receptor status. All of the primary ovarian cancers and cell lines expressed BRG-1. Estrogen stimulation of two cell lines expressing ER (SKOV3, OVCA 432) elicited low levels of ER-mediated transcription that was not enhanced by BRG-1 transfection. ICI 182,780 did not induce cell cycle arrest in these cell lines, but there was evidence of downregulation of ER, indicating a ligand-receptor interaction. However, estrogen did not elicit increased transcription of estrogen-responsive genes (PR, myc, fos, pS2). Conclusion:

Inappropriate expression of the nuclear corepressors N-CoR and SMRT or the coactivator BRG-1 does not underlie the resistance of ovarian cancers to hormonal therapy. Further studies are needed to elucidate the mechanisms underlying the inability of ovarian cancers to undergo ER-mediated transcription if we hope to understand their resistance to hormonal therapy.

Jain, V., M. Longo, et al. (2000). "Expression of receptors for corticotropin-releasing factor in the vasculature of pregnant rats." Journal of the Society for Gynecologic Investigation 7(3): 153.

<http://www.sciencedirect.com/science/article/B6T93-40J1DY9-3/2/a9971c6dce8ef9a3f0fb9dafb5d82db9>

Objective:To identify and localize the receptor(s) responsible for modulating vascular effects of corticotropin-releasing factor (CRF) during pregnancy.**Methods:**Reverse transcriptase-polymerase chain reaction (RT-PCR), competitive RT-PCR, and Western blot analyses were used to study the expression of CRF receptors (CRFR1, CRFR2[alpha], and CRFR2[beta]) in the aorta and uterine vascular bed of nonpregnant and late (day 18) and term pregnant (day 22) Sprague-Dawley rats. Immunohistochemistry was done to localize the CRF receptor in the aortic wall. There were six rats in each study group.**Results:**Only CRFR2[beta] was identified in the aorta and uterine vascular bed by RT-PCR and Western blot analyses. The PCR product was sequenced to confirm its identity. Competitive RT-PCR and Western blot analyses showed that expression of CRFR2[beta] is not different in late pregnancy compared with the nonpregnant but is decreased at term. Immunohistochemistry showed high expression of CRFR2[beta] on the aortic endothelial surface but low expression in the smooth-muscle layer.**Conclusion:**Only CRFR2[beta] is expressed in vasculature of nonpregnant and pregnant rats and may mediate the vasorelaxant effect of CRF. This receptor is present predominantly in the vascular endothelium and to a lesser extent in the smooth muscle. The expression of CRF receptor in pregnant rat vasculature is down-regulated at term of gestation.

Nichols, J. E., S. E. Bulun, et al. (1995). "Effects of conditioned medium from different cultured cell types on aromatase expression in adipose stromal cells." Journal of the Society for Gynecologic Investigation 2(1): 45.

<http://www.sciencedirect.com/science/article/B6T93-3YCDS23-SM/2/b22b7fc3374307661301b11a046cfff>

To determine whether serum-free (SF) conditioned media (CM) from several human breast cancer cell lines and primary stromal cell cultures contain factor(s) that mimic the marked stimulatory effects of serum on aromatase activity and aromatase P450 (P450arom) gene expression in adipose stromal cells in culture (ASC) in the presence of dexamethasone (DEX). Adipose stromal cells, harvested from fresh adipose specimens, were grown to confluence, switched to SF media, and then incubated in the presence or absence of DEX with CM from T47-D breast cancer cells, pre-treated with or without 17[beta]-estradiol (E2), and with CM from stromal cell cultures. Aromatase activity of the ASC was determined by the [3H]water release assay. Total RNA was isolated, and reverse transcription-polymerase chain reactions were performed to determine the expression of various 5'-termini. T47-D CM stimulated aromatase activity in a concentration-dependent manner, similar to that of serum, in ASC incubated with DEX. Estrogen potentiated this in a dose-dependent fashion. The ASC CM and endometrial stromal cell CM also markedly induced aromatase activity in ASC. Heat inactivation destroyed the stimulating ability of CM. The majority of P450arom 5'-termini expressed by ASC incubated with CM plus DEX contained the promoter 1.4-specific sequence. Conditioned media from several breast cancer cell lines and primary stromal cell cultures can mimic the effects of serum in the presence of DEX to stimulate aromatase activity in ASC. These results suggest that undefined,

heat-labile and proteinaceous factors are present in CM that stimulate P450arom expression in a fashion similar to that of serum.

Schondorf, T., A. Dostal, et al. (2000). "Single mutations of the PTEN gene in recurrent ovarian carcinomas." Journal of the Society for Gynecologic Investigation 7(5): 313.

<http://www.sciencedirect.com/science/article/B6T93-41DHPR0-8/2/9995177120a8a93c691e3ff7cf9fa9d0>

Objective:To establish the role of phosphate and tensin homologue on chromosome 10 (PTEN) mutations in tumorigenesis of the ovary, we determined the mutational spectrum of the PTEN gene in surgical specimens of ovarian carcinomas. **Methods:**The study group consisted of 86 ovarian cancer specimens (18 fluids, 68 solid specimens), including 30 primary ovarian cancer specimens and 56 of relapsed ovarian cancer from women with a median age of 57.9 years and a range of 27-85 years. Each of the nine exons of the PTEN gene was amplified separately by polymerase chain reaction (PCR). Both strands of the PCR products were sequenced directly by standard cycle sequencing procedures and subsequent computer-aided alignments with the wild-type sequence. **Results:**In ascitic fluids of two women with recurrence of cancer, we observed mutations: one seven-base-pair insertion at codon 52 (GATGATG) and the other a base-pair substitution resulting in an amino acid change (T131I). We found no mutation in the primary ovarian cancers. **Conclusions:**Our data indicate that PTEN mutations have a subordinate role in tumorigenesis of the ovary.

Thaete, L. G., M. G. Neerhof, et al. (2003). "Infusion of exogenous platelet-activating factor produces intrauterine growth restriction in the rat." Journal of the Society for Gynecologic Investigation 10(3): 145.

<http://www.sciencedirect.com/science/article/B6T93-48BBJVM-5/2/ca59f0522fb73a70369bd0fbcc17d6e3>

Objective:To determine the impact of exogenous platelet-activating factor (PAF) on pregnancy outcome in the rat. **Methods:**Carbamyl-PAF (0.05, 0.5, or 5.0 [μg/kg per hour) or vehicle was infused intravenously for 7 days by osmotic pump into timed pregnant rats. Infusion was begun on day 14 of a 22-day gestation. Maternal mean arterial blood pressures were measured on days 1, 4, and 7 of the infusion. On gestational day 21 (PAF infusion day 7), fetal and placental weights and viability were evaluated at hysterotomy. Uterine and placental PAF receptor expression was analyzed by reverse transcription-polymerase chain reaction and agarose gel electrophoresis. Data were analyzed by analysis of variance, [chi]², or the Mann-Whitney U test as appropriate. **Results:**Fetal weights were dose-dependently lower than control, by 19% and 35%, respectively, at dosages of 0.5 and 5.0 [μg/kg per hour (P P P **Conclusions:**Exogenous PAF produces dose-dependent fetal growth restriction in the rat. Placental growth is particularly sensitive to PAF and, coupled with the dose-dependent decline in fetal growth, suggests a dose-dependent decline in function. An elevated level of PAF is detrimental to fetal growth and well-being in the rat.

Toivonen, S., E.-L. Romppanen, et al. (2004). "Low-activity haplotype of the microsomal epoxide hydrolase gene is protective against placental abruption." Journal of the Society for Gynecologic Investigation 11(8): 540.

<http://www.sciencedirect.com/science/article/B6T93-4DN176B-1/2/1731415704f3a20f3780599fadb340ef>

ObjectiveWe wanted to determine whether genetic variability in the gene encoding microsomal epoxide hydrolase (EPHX) contributes to individual differences in susceptibility to the occurrence of placental abruption.**Methods**The study involved 117 women with placental abruption and 115 healthy control pregnant women who were genotyped for two single nucleotide polymorphisms (SNPs), T-->C (Tyr113His) in exon 3 and A-->G (His139Arg) in exon 4, in the EPHX gene. Chi-square analysis was used to assess genotype and allele frequency differences between the women with placental abruption and the control group. In addition, single-point analysis was expanded to pair of loci haplotype analysis to examine the estimated haplotype frequencies of the two SNPs, of unknown phase, among the women with placental abruption and the control group. Estimated haplotype frequencies were assessed using the maximum-likelihood method, employing an expectation-maximization algorithm.**Results**Single-point allele and genotype distributions in exons 3 and 4 of the EPHX gene were not statistically different between the groups. However, in the haplotype estimation analysis we observed a significantly decreased frequency of haplotype C-A (His113-His139) among the placental abruption group compared with the control group ($P = .007$). The odds ratio for placental abruption associated with the low-activity haplotype C-A (His113-His139) was 0.552 (95% confidence interval, 0.358 to 0.851).**Conclusions**The use of two intragenic SNPs jointly in haplotype analysis of association demonstrated that the genetically determined low-activity haplotype C-A (His113-His139) was significantly less frequent in women with placental abruption.

Journal of Thoracic and Cardiovascular Surgery (1)

Absi, T. S., I. I. I. T. M. Sundt, et al. (2003). "Altered patterns of gene expression distinguishing ascending aortic aneurysms from abdominal aortic aneurysms: complementary DNA expression profiling in the molecular characterization of aortic disease." Journal of Thoracic and Cardiovascular Surgery **126**(2): 344.

<http://www.sciencedirect.com/science/article/B6WMF-4991FX6-12/2/f7aa9019d150c38afc83b882236fcc70>

ObjectivesThe purpose of this study was to profile altered patterns of gene expression that characterize degenerative ascending thoracic aortic aneurysms and to compare these patterns with those observed for infrarenal abdominal aortic aneurysms.**Methods**Full-thickness aortic wall tissues were obtained during surgical repair of degenerative thoracic aortic aneurysms and infrarenal abdominal aortic aneurysms ($n = 4$ each), with normal thoracic and abdominal aortas from organ transplant donors used as control preparations. Radiolabeled complementary DNA was prepared for each specimen and hybridized to complementary DNA microarrays, and differential levels of gene expression between aneurysmal and normal aortic tissues at each site were assessed by parametric statistics.**Results**Of 1185 genes examined, 112 (9.5%) were differentially expressed ($P < .05$) including yes-1 oncogene, mitogen-activated protein kinase 9, and intercellular adhesion molecule 1/CD54). Results for 9 genes were independently confirmed by quantitative reverse transcriptase-polymerase chain reaction.**Conclusions**Thoracic aortic aneurysms and infrarenal abdominal aortic aneurysms exhibit distinct patterns of gene expression relative to normal aorta from the same sites, with most alterations being unique to each disease. Degenerative aneurysms arising in different locations are thus characterized by a high degree of molecular heterogeneity, reflecting different pathophysiologic mechanisms.

Colonnello, J. S., K. A. Hance, et al. (2003). "Transient exposure to elastase induces mouse aortic wall smooth muscle cell production of MCP-1 and RANTES during development of experimental aortic aneurysm." Journal of Vascular Surgery **38**(1): 138.

<http://www.sciencedirect.com/science/article/B6WMJ-48XS59W-14/2/2b1b3074f6a24f00b5c77a892e255d37>

Purpose Abdominal aortic aneurysm (AAA) is associated with chronic transmural inflammation and destruction of the elastic media. The purpose of this study was to elucidate molecular mechanisms that might orchestrate leukocyte recruitment into the outer aortic wall by determining whether CC chemokines contribute to development of aneurysm degeneration in an elastase-induced mouse model of AAA. **Methods** Adult male C57BL/6J mice underwent transient elastase perfusion of the abdominal aorta to induce development of AAA. At various intervals after elastase perfusion (0, 4, 7, 14 days), real-time reverse transcription polymerase chain reaction and enzyme-linked immunosorbent assays were used to measure aortic wall expression of the CC ([beta]) chemokines, monocyte chemoattractant protein-1 (MCP-1) and regulated on activation, normal T-cell expressed and secreted (RANTES). Expression of these chemokines by cultured mouse aortic smooth muscle cells (AoSMC) was similarly assessed after transient (5 minutes) exposure to elastase solutions in vitro. **Results** Mouse aortic diameter (mean +/- SEM) increased to aneurysmal proportions by 14 days after elastase perfusion (from 0.51 +/- 0.03 mm to 1.34 +/- 0.32 mm; 163% increase; P < .001) of MCP-1 and RANTES, despite concomitant decrease in cell numbers. **Conclusions** Increased mouse aortic wall expression of MCP-1 and RANTES occurs early in development of elastase-induced AAA and before onset of the chronic inflammatory response. Moreover, elastase directly stimulates AoSMC chemokine production in vitro. Elastase-induced medial SMC production of CC chemokines may therefore provide an important link between enzymatic injury, leukocyte recruitment, and aneurysmal degeneration of the aortic wall.

Curci, J. A., D. Mao, et al. (2000). "Preoperative treatment with doxycycline reduces aortic wall expression and activation of matrix metalloproteinases in patients with abdominal aortic aneurysms." Journal of Vascular Surgery **31**(2): 325.

<http://www.sciencedirect.com/science/article/B6WMJ-4CYY107-2C/2/010445b60f9b2fc0693172a98c072886>

Purpose: Matrix metalloproteinases (MMPs) are considered to play a central role in the pathogenesis of abdominal aortic aneurysms (AAAs). Doxycycline (Dox) has direct MMP-inhibiting properties in vitro, and it effectively suppresses the development of elastase-induced AAAs in rodents. The purpose of this study was to determine if treatment with Dox suppresses MMPs within human aneurysm tissue and to elucidate the molecular mechanisms underlying this effect. **Methods:** Aneurysm tissues were obtained from 15 patients with an AAA, eight of whom had been treated with Dox before surgery (100 mg orally twice a day for 7 days). Protein extracts were examined by means of gelatin zymography and immunoblot analysis, and RNA was examined by means of reverse transcription-polymerase chain reaction (R-TPCR). The effects of Dox on MMP production were further examined in human THP1 mononuclear phagocytes in

vitro. Results: No detectable difference was found between groups by using substrate zymography as a means of assessing total AMP activity, but Dox treatment was associated with a slight (24.4%) reduction in the activated fraction of 72-kDa gelatinase (MMP-2; P P P Conclusion: In addition to its recognized effects as a direct MMP antagonist, Dox may influence connective tissue degradation within human aneurysm tissue by reducing monocyte/macrophage expression of MMP-9 mRNA and by suppressing the post-translational processing (activation) of proMMP-2. Through this complementary combination of mechanisms, treatment with Dox may be a particularly effective strategy for achieving MAP inhibition in patients with an AAA.

Journal of Virological Methods (213)

Aberham, C., C. Pendl, et al. (2001). "A quantitative, internally controlled real-time PCR Assay for the detection of parvovirus B19 DNA." Journal of Virological Methods **92**(2): 183.

<http://www.sciencedirect.com/science/article/B6T96-42D81PP-9/2/fde3d3e7f7f43cb0f896041e1ff48bdd>

Parvovirus B19 is an erythrovirus causing diverse clinical manifestations ranging from asymptomatic or mild, to more severe outcomes in, for example, immune-compromised patients. B19 is spread primarily via the respiratory route, but it can also be transmitted via blood and blood products. Viral loads in blood or plasma donations amount up to 1011 genome equivalents/ml. Therefore, screening of plasma for fractionation for the presence of B19 and removal of highly loaded donations is a way to limit considerably the input of B19 into production pools and to improve further the safety of plasma products. An assay for the quantitative detection of B19 DNA, based on real-time PCR using ABI Prism SDS7700 (TaqMan) is described here. This assay allows precise quantitation of viral loads over 7 orders of magnitude. An exogenous internal control (internal quality marker) is included in each individual sample to prevent false negative results. A linearized plasmid is used as an internal quality marker that contains the identical sequence of the B19 target sequence but with an altered probe hybridization site. This allows co-amplification of B19 and internal quality marker and co-detection of FAM (6-carboxyfluorescein) or VIC labeled probes respectively. The assay is validated according to current guidelines (of the International Conference on Harmonization, Paul Ehrlich Institute, and the Council of Europe) and is optimized for high throughput screening.

Agnes, F., J. M. Crance, et al. (1994). "Separate detection of the two complementary RNA strands of hepatitis A virus." Journal of Virological Methods **49**(3): 323.

<http://www.sciencedirect.com/science/article/B6T96-476TY1K-8/2/edb199dcce304e64fed3c2484ef8ad1f>

The minus strand of hepatitis A virus can be detected specifically by reverse transcription and polymerase chain reaction amplification in infected cell culture extracts. Several controls gave evidence that the amplified fragment actually used the minus strand as initial template. Non-thermostable reverse transcriptase was not efficient for this purpose because of self-priming of the positive-stranded viral RNA during the reverse transcription step. This problem was overcome by the use of the thermostable rTth DNA polymerase that also has reverse transcriptase activity in the presence of Mn²⁺.

Albrecht, B., N. D. Collins, et al. (1998). "Quantification of human T-cell lymphotropic virus type 1 proviral load by quantitative competitive polymerase chain reaction." Journal of Virological Methods **75**(2): 123.

<http://www.sciencedirect.com/science/article/B6T96-3V5F5S6-1/2/d33602ffb9310033bf5828a1d6013b4>

The polymerase chain reaction (PCR) has been established as a highly sensitive technique for detection of viral DNA or RNA. However, due to inherent limitations of PCR the amount of amplified product often does not correlate with the initial amount of template DNA. This is particularly true for PCR detection of viral infections that are characterized by low in vivo viral copy numbers in certain stages of the infection, such as human T-cell lymphotropic virus type 1 (HTLV-1) and simian T-cell lymphotropic virus type 1 (STLV-1). Therefore, we developed a quantitative competitive polymerase chain reaction (qcPCR) for detection of HTLV-1 and STLV-1 proviral DNA. The assay was optimized using an infectious HTLV-1 clone, ACH, HTLV-1 infected cell lines, MT-2.6 and HUT-102 and STLV-1 infected lines Kia and Matsu. Applicability of this system was demonstrated by determining HTLV-1 proviral load in peripheral blood mononuclear cells (PBMC) of human subjects with HTLV-1 associated diseases and an asymptomatic carrier as well as rabbits infected experimentally. This qcPCR method, the first designed specifically for HTLV-1 and STLV-1, will provide an important tool for pathogenesis studies of HTLV-1 and for evaluating the efficacy of antiviral drugs and vaccines against the viral infection using animal models.

Alcaraz, C., F. Rodriguez, et al. (1995). "Highly specific confirmatory Western blot test for African swine fever virus antibody detection using the recombinant virus protein p54." Journal of Virological Methods **52**(1-2): 111.

<http://www.sciencedirect.com/science/article/B6T96-3YXC151-W/2/4eb43f695bf6fc6097bd9155e7b760e0>

A Western blot technique using a recombinant protein has been developed to confirm positive results obtained in African swine fever (ASF)-specific antibody detection by ELISA. The new confirmatory Western blot is based on the use of protein p54, one of the most antigenic ASF virus structural proteins, expressed in *Escherichia coli* fused to the N-terminus of MS2 polymerase. The recombinant Western blot assay was highly specific and equally sensitive for ASF virus-infected pigs detection as the conventional Western blot, which uses virus-induced proteins ranging in molecular weight between 23 and 35 kDa. The novel Western blot assay provides a simpler interpretation of the test, eliminates the possibility of false-positive reactions produced by cellular compounds that contaminate the antigen employed in the conventional technique, and avoids the use of live virus in antigen production.

Argaw, T., A. Ritzhaupt, et al. (2002). "Development of a real time quantitative PCR assay for detection of porcine endogenous retrovirus." Journal of Virological Methods **106**(1): 97.

<http://www.sciencedirect.com/science/article/B6T96-46TBF6J-H/2/ab392041d9a6b7f599146874bab1b8f6>

Real time PCR technology was applied to the development of assays for detection and quantitation of porcine endogenous retrovirus (PERV) RNA and DNA sequences in tissues and

cells of human or animal origin. A plasmid construct encoding the PERV-pol gene or the in vitro transcribed RNA derived from the plasmid (cRNA) serves as a standard template for amplification of a 178 bp fragment. This study showed that the detection of this target sequence was linear over a range from 20 copies to 2 million copies of the plasmid and from 100 copies to 1 million copies of the cRNA. In addition, amplification of the target sequence was not inhibited by the presence of exogenous genomic DNA. These results demonstrate that a real time (TaqMan-based) PCR or RT-PCR assay can provide a sensitive, reproducible, and robust method for detecting and quantifying PERV DNA or RNA sequences in samples of human or guinea pig origin.

Ault, G. S., C. F. Ryschkewitsch, et al. (1994). "Type-specific amplification of viral DNA using touchdown and hot start PCR." Journal of Virological Methods **46**(2): 145.

<http://www.sciencedirect.com/science/article/B6T96-476F69S-BD/2/caa598ec4d1318cace2bb44a0c627ea5>

Two types of JC virus (JCV) are found in infected brain and kidney tissues. A highly reliable PCR assay to determine viral type in tissue is presented. This type-specific system is analogous to allele-specific PCR used to detect point mutations in cellular genes. Specific amplification of two fragments, using four pairs of type-specific primers, is based on a single nucleotide difference at the 3'-ends of the primers. A combination of three conditions in the PCR reaction was required for specificity: 'hot start', a ramped ('touchdown') cycle profile, and a slightly lowered molar concentration of the specific primers and dNTPs. Efficient yield of PCR product is not lost under these conditions, and even the least selective mismatches (C:A and T:G) provided specific amplification. Type-specific restriction enzyme sites within the amplified fragments confirm type designation.

Avellon, A., P. Perez, et al. (2001). "Rapid and sensitive diagnosis of human adenovirus infections by a generic polymerase chain reaction." Journal of Virological Methods **92**(2): 113.

<http://www.sciencedirect.com/science/article/B6T96-42D81PP-2/2/540b7580d8d9f11b8c1865872705eb3c>

A new adenovirus specific nested polymerase chain reaction (PCR) method is described. It was designed inside the hexon protein gene of the adenovirus genome, and was able to detect DNA of all 47 human adenovirus types in a wide range of clinical samples. A sensitive internal control system able to assure proper analytical conditions for the amplification of as few as 100 molecules of a heterologous DNA was included to avoid false negative results. Sensitivity was estimated at about 10 molecules per tube of a plasmid containing an insert of the first amplification product. The method was able to detect adenovirus infection in 31/43 conjunctival scrapings from patients with acute kerato conjunctivitis 10/40 nasopharyngeal aspirates from patients admitted to hospital with acute respiratory disease and 2/26 urine samples from patients with haemorrhagic cystitis with better sensitivity than cell culture or rapid diagnosis by antigen detection by immunofluorescence (IF) in the case of respiratory specimens. Only two of 17 stools positive for a group F adenovirus specific latex immunoassay were PCR negative. The internal control system avoided a false negative result on another two stool samples. In conclusion, the method described below was shown to be useful for rapid diagnosis of adenovirus infections with higher sensitivity than antigen detection by IF.

Baines, J. E., R. M. McGovern, et al. (2005). "Consensus-degenerate hybrid oligonucleotide primers (CODEHOP) for the detection of novel papillomaviruses and their application to esophageal and tonsillar carcinomas." Journal of Virological Methods **123**(1): 81.

<http://www.sciencedirect.com/science/article/B6T96-4DNB3BK-2/2/42b0ea14114390dc20621805c2b654de>

Human papillomaviruses (HPVs) have been identified in 99% of cervical tumors. Considerable speculation exists about the role of HPV in cancer at other sites, such as skin, esophagus, and lung. One barrier to the study of HPV in extragenital tumors may be the inability to detect novel HPV types. Our objective was to design broad-range primers for detecting papillomaviruses from any group in the HPV Sequence Database. Complete L1 protein sequences were aligned and 11 blocks of conserved protein sequences were identified. Primers were designed in the corresponding nucleotide regions of five blocks. One pair of primers, ME and MH, derived from blocks E and H, appeared promising when compared with established consensus primers. To improve the sensitivity for detection of multiple papillomavirus types, ME/MH primers were split into several primers with the 5' regions matched to individual papillomavirus supergroups. Compared with the commonly used MY09/11 primer set, our primer sets were broader in range and more sensitive against most papillomavirus types tested. Application of these primers to esophageal and tonsillar carcinomas identified no novel HPV types but confirmed a high level of sensitivity for detecting HPV from these clinical samples. These primers should facilitate the search for novel papillomaviruses.

Barbezange, C. and V. Jestin (2002). "Development of a RT-nested PCR test detecting pigeon Paramyxovirus-1 directly from organs of infected animals." Journal of Virological Methods **106**(2): 197.

<http://www.sciencedirect.com/science/article/B6T96-46WSX8S-2/2/5213504c066b45784a6c0b93533807ca>

A RT-nested PCR that amplifies part of the conserved nucleoprotein gene of avian Paramyxovirus type 1 is described. The technique allowed the detection of pigeon Paramyxovirus type 1 (pPMV-1) virus directly from a wide range of infected chicken and pigeon organs, and should be able to detect typical Newcastle disease viruses too. Compared with the reference method, the developed RT-nested PCR was found more sensitive, as it was able to detect virus genome in infected pigeon organs at late stage of infection, when virus isolation failed. Such a molecular technique represents an alternative method of diagnosis for research purposes on pPMV-1 variants, for example to study pathogenesis aspects of the infection or to assess the efficacy of vaccines.

Barlic-Maganja, D. and J. Grom (2001). "Highly sensitive one-tube RT-PCR and microplate hybridisation assay for the detection and for the discrimination of classical swine fever virus from other pestiviruses." Journal of Virological Methods **95**(1-2): 101.

<http://www.sciencedirect.com/science/article/B6T96-433NRB5-B/2/a24675b98a618b42aeb421941d4670b5>

Rapid, sensitive and specific laboratory diagnostic methods are necessary to confirm outbreaks of classical swine fever. The detection of classical swine fever virus (CSFV) and its discrimination from other pestiviruses can be achieved by virus isolation on cell culture, antigen detection, or molecular methods. To reduce the time and the number of steps in the diagnostic procedure a

sensitive and rapid detection method based on specific amplification of the pestiviral RNA by one-step reverse transcription-polymerase chain reaction (RT-PCR) followed by detection and differentiation of the amplification products by pestivirus-, bovine viral diarrhoea virus- (BVDV-) and CSFV-specific capture probe hybridisation and colorimetric assay in microwell plates (enzyme linked immunosorbent assay (ELISA)) was developed. Two different methods using two gene regions for pestivirus RT-PCR amplification were carried out. One pair of primers was selected from the 5'-UTR region and the second one from the gene region coding for Npro, C and E0 proteins. The designed oligonucleotide primers were used for several pestivirus reference strains as well as for some field isolates detection in cell culture supernatants and in clinical specimens. The specificity and sensitivity of both methods were compared using EZ rTth RNA PCR kit and ACCESS RT-PCR system for combined RT-PCR assay. The use of one-step RT-PCR eliminates the additional manipulations that are generally required for a two reaction system and limits the risk of carry-over contamination. Labelling of PCR products with digoxigenin (DIG) during the amplification reaction enables colorimetric assessment of hybridisation reactions. For solution hybridisation pestivirus-, BVDV- and CSFV-specific biotin-labelled capture probes were used. By serial dilutions of DIG-labelled PCR products the RT-PCR-ELISA was found to be 100-times more sensitive than the conventional agarose gel electrophoresis. Higher sensitivity of RT-PCR-ELISA detection using specific biotin-labelled probes offers the opportunity to eliminate strain specific nested PCR and to overcome the problems with contamination and false positive results.

Barlough, J., N. East, et al. (1994). "Double-nested polymerase chain reaction for detection of caprine arthritis-encephalitis virus proviral DNA in blood, milk, and tissues of infected goats." Journal of Virological Methods **50**(1-3): 101.

<http://www.sciencedirect.com/science/article/B6T96-47DKYF8-C/2/56659fd9129ad03f9351de6729c6c776>

A nested polymerase chain reaction (PCR) for detecting proviral DNA of caprine arthritis-encephalitis virus (CAEV) in biological samples was developed. Primers for both gag and pol sequences of the CAEV genome were included in a single tube for simultaneous amplification ('double' PCR), and the resulting bands were resolved visually in ethidium bromide-stained agarose gels. Internal gag and pol probes were used to verify the identity of the amplified products by non-radioactive Southern hybridization. Final confirmation of the identity of representative PCR bands was provided by DNA sequence analysis. A comparison between the PCR and an antibody ELISA (with recombinant CAEV p28 as target) using 141 caprine blood samples indicated very strong agreement between the two assays ($\kappa = 0.912$). Four of 7 goats with indeterminate ELISA results were PCR-positive as were 5 of 40 (12.5%) seronegative goats, most probably indicating delayed seroconversion. Eleven of 27 goats (41%) PCR-positive on blood had detectable CAEV proviral DNA in milk. Proviral DNA was also detected in lung, mesenteric lymph node, bone marrow, synovial membrane, and mammary gland of a seropositive, clinically affected goat, but not in equivalent tissues of a healthy seronegative goat.

Beaulieux, F., M. M. Berger, et al. (2003). "RNA extraction and RT-PCR procedures adapted for the detection of enterovirus sequences from frozen and paraffin-embedded formalin-fixed spinal cord samples." Journal of Virological Methods **107**(2): 115.

<http://www.sciencedirect.com/science/article/B6T96-47DTDTF-3/2/2adec925f3d102f950d4be0508ecb015>

Methods for detecting enterovirus RNA in both paraffin-embedded, formalin-fixed and frozen spinal cord sections from amyotrophic lateral sclerosis (ALS) patients were established. A

proteinase K digestion following the deparaffinization procedure was required for the fixed spinal cord sections, whereas only one step of crushing in phosphate buffered saline was necessary for the frozen samples prior to the extraction of the RNA. With an optimized reverse transcription and PCR procedure, enterovirus RNA could be detected from frozen and fixed archival spinal cord samples.

Bellau-Pujol, S., A. Vabret, et al. "Development of three multiplex RT-PCR assays for the detection of 12 respiratory RNA viruses." Journal of Virological Methods **In Press, Corrected Proof**
<http://www.sciencedirect.com/science/article/B6T96-4FJTNTM-2/2/0ba5a40b32fe1ff28df50d75b2fab22a>

Three multiplex hemi-nested RT-PCR assays were developed to detect simultaneously 12 RNA respiratory viruses: influenza viruses A, B and C, human respiratory syncytial virus (hRSV), human metapneumovirus (hMPV), parainfluenza virus types 1-4 (PIV-1, -2, -3 and -4), human coronavirus OC43 and 229E (HCoV) and rhinovirus (hRV). An internal amplification control was included in one of the RT-PCR assays. The RT-PCR multiplex 1 and the hemi-nested multiplex 1 detected 1 and 0.1 TCID₅₀ of RSV A, respectively, and 0.01 and 0.001 TCID₅₀ of influenza virus A/H3N2, respectively. Two hundred and three nasal aspirates from hospitalised children were retrospectively tested in comparison with two conventional methods: direct immunofluorescence assay and viral isolation technique. Almost all samples (89/91) that were positive by immunofluorescence assay and/or viral isolation technique were detected by the multiplex assay. This method also detected an additional 85 viruses and 33 co-infections. The overall sensitivity (98%), rapidity and enhanced efficiency of these multiplex hemi-nested RT-PCR assays suggest that they would be a significant improvement over conventional methods for the detection of a broad spectrum of respiratory viruses.

Belliot, G. M., R. L. Fankhauser, et al. (2001). "Characterization of 'Norwalk-like viruses' and astroviruses by liquid hybridization assay." Journal of Virological Methods **91**(2): 119.

<http://www.sciencedirect.com/science/article/B6T96-426XYG8-3/2/ee396f5d131df9dded538957d49b01ce>

'Norwalk-like viruses' (NLVs) and human astroviruses are causative agents of gastroenteritis in all age-groups. The typing of these agents is generally done by nucleotide sequencing, blot hybridization, or enzyme immunoassay. These techniques are expensive, time-consuming, and sometimes require scarce reagents, which limits the typing of NLVs and astroviruses to a few reference laboratories. This report describes a liquid hybridization assay that uses broadly reactive probes whose sequences are based on data from specimens in collections available at CDC and GenBank. Two astrovirus genogroup-specific probes were designed and tested successfully on 26 wild strains from all serotypes. Fourteen GII and 16 GI representative NLV strains were typed without cross-hybridization by using P1B- and P2A-specific probes, described previously, and new P2B- and P1A-specific probes. Analysis of the specificity of the probes, the effect of the mismatches during hybridization, and the sensitivity of hybridization assay demonstrates this method to be a rapid and simple technique for molecular typing of NLVs and preliminary characterization of astroviruses.

Bennett, J. M., S. Kaye, et al. (1999). "A quantitative PCR method for the assay of HIV-1 provirus load in peripheral blood mononuclear cells." Journal of Virological Methods **83**(1-2): 11.

<http://www.sciencedirect.com/science/article/B6T96-3XVPG88-2/2/2e45f7793c78e80a591462826d37427c>

The use of high activity antiretroviral therapies (HAART) to treat HIV-infected patients frequently results in the long-term suppression of plasma virus RNA loads below levels detectable by current assays. The measurement of provirus DNA load in peripheral blood mononuclear cells provides a means of continuing to monitor the efficacy of treatment and the decline in reservoirs of latent virus. A quantitative PCR assay was developed for HIV-1 provirus using a three-point internal calibrator system to give high reproducibility and accuracy at the low copy numbers of provirus seen in clinical samples. Provirus DNA copies are related to cell number in the samples using a fluorescent dye-binding assay for measurement of input DNA. The assay agreed closely with an end-point dilution PCR and gave accurate quantification of extracts from an HIV-1 infected continuous cell line containing known provirus copy numbers. The inclusion of a second primer set in the LTR region of the HIV-1 genome, optimised to non-clade-B virus strains improved the detection and quantification of samples from patients infected with genetically divergent virus strains. Application of the assay to clinical trial patients showed no relationship between changes in provirus DNA loads and plasma virus RNA and changes in provirus load over 24 weeks were small.

Bettinger, D., C. Mougin, et al. (1994). "Rapid detection of active cytomegalovirus infection by in situ polymerase chain reaction on MRC5 cells inoculated with blood specimens." Journal of Virological Methods **49**(1): 59.

<http://www.sciencedirect.com/science/article/B6T96-476F6X3-KS/2/4277fbf8076a971214cbc06ee1d9a158>

An in situ polymerase chain reaction was developed to amplify immediate early genes of human cytomegalovirus in cells cultured in a 96 well plate and infected with leukocytes. The technical parameters enabling optimal detection of the DNA sequences were defined. The key to this method is the fixation of cells, which facilitates the access of the PCR mixture into the cell nuclei and preserves cell morphology. Such a technique could have wide application for the detection and identification of other infectious viruses in cultured cells very early after inoculation of clinical samples.

Beuret, C. (2004). "Simultaneous detection of enteric viruses by multiplex real-time RT-PCR." Journal of Virological Methods **115**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-49V3JJG-1/2/1cf1f7ec80bbf36619d849b77af86662>

A multiplex real-time RT-PCR protocol for the simultaneous detection of noroviruses ("Norwalk-like viruses") of genogroups I and II, human astroviruses and enteroviruses is described. The protocol was developed and evaluated using the LightCycler(TM) and corresponding SYBR Green reagents. New primers were designed within conserved genome regions to optimize the detection range of virus subtypes of each genus. To enable the development of a multiplex PCR assay within one tube (capillary), similar mastermix- and cycling-conditions were respected for each individual primer system. Subsequent melting curve analysis allowed the determination of possible dual-contaminations of entero- and noro- or astroviruses by the formation of dual peaks. Special care was taken to minimize the loss of sensitivity, since the detection of small viral contaminations is a crucial parameter especially for food analysis. The multiplex assay was compared successfully to the single SYBR Green assay, and revealed to be at least 10 times

more sensitive than the one obtained with an endpoint PCR thermocycler protocol published previously.

Binder, T., W. Siegert, et al. (1999). "Identification of human cytomegalovirus variants by analysis of single strand conformation polymorphism and DNA sequencing of the envelope glycoprotein B gene region-distribution frequency in liver transplant recipients." Journal of Virological Methods **78**(1-2): 153.

<http://www.sciencedirect.com/science/article/B6T96-3W07P76-G/2/dc26e56fe1796ed67a375466047c1a9e>

Single strand conformation polymorphism analysis (SSCP) of PCR-amplified DNA and subsequent DNA sequencing of human cytomegalovirus (HCMV) glycoprotein B (gB) gene were applied to identify known HCMV strains and to detect new virus variants. 61 HCMV PCR positive patients were studied out of a cohort of 410 patients after liver transplantation (LTX). SSCP was able to distinguish between strains Davis, AD169, and Towne, and in addition could identify five new virus variants (Berlin B, C, E, F, and H). Their frequency, gB and gH types were determined. Simultaneous infections with two or three strains or variants, as well as a switch from one virus to another virus were observed during long-term follow-up. No correlation between the occurrence of certain virus strains or gB types and defined clinical manifestations of HCMV infection after LTX was drawn.

Black, E. M., J. P. Lowings, et al. (2002). "A rapid RT-PCR method to differentiate six established genotypes of rabies and rabies-related viruses using TaqMan(TM) technology." Journal of Virological Methods **105**(1): 25.

<http://www.sciencedirect.com/science/article/B6T96-45TTWC2-4/2/84fb96b7a1635f9735ea69436c30ec10>

A rapid and sensitive reverse transcriptase-polymerase chain reaction (RT-PCR) assay incorporating TaqMan(TM) probes has been developed that can distinguish among the six established rabies and rabies-related virus genotypes. TaqMan(TM) probes were designed and validated against 106 rabies and rabies-related virus isolates, one isolate of the Australian bat Lyssaviruses (genotype 7), and 18 other non-rabies viruses important in the veterinary field. The N gene was used as the target for the probes as it is well conserved and has been intensively used to genotype rabies isolates. Additionally, it was found to contain regions specific to each genotype conducive to probe design. The RT-PCR assay described amplifies a portion of the nucleoprotein gene of all 107 rabies and rabies-related viruses, but none of the other viruses tested. Inclusion of TaqMan(TM)-genotype-specific probes in the RT-PCR assay permits rapid identification of the virus present. By combining RT-PCR with TaqMan(TM) genotyping probes suspect rabies virus isolates can be identified in a single closed tube system that prevents potential PCR-product carry over contamination.

Bockstahler, L. E., P. G. Carney, et al. (1992). "Detection of Junin virus by the polymerase chain reaction." Journal of Virological Methods **39**(1-2): 231.

<http://www.sciencedirect.com/science/article/B6T96-476F6MB-HT/2/d5e47bbe329918cde17901be1436f7dd>

Argentine hemorrhagic fever is an often fatal human disease caused by Junin virus, an RNA-containing virus and member of the Arenavirus family. This virus was detected in vitro by the polymerase chain reaction (PCR) procedure. A pair of Junin virus-specific PCR DNA oligonucleotide primers and an oligonucleotide probe were designed from a known portion of the viral RNA sequence. RNA was isolated from Junin virus-infected monkey kidney cells and used to produce complementary DNA (cDNA) by reverse transcription. A DNA segment, 151 +/- 24 bp long, was amplified from this cDNA and characterized by agarose gel electrophoresis and Southern blot hybridization with the Junin virus-specific DNA probe. Sensitivity experiments showed that Junin virus could be detected with nanogram quantities of RNA isolated from virus-infected cells. The rapid and sensitive assay described here may contribute towards the development of a procedure for the early diagnosis of Argentine hemorrhagic fever.

Boerner, B., W. Weigelt, et al. (1999). "A sensitive and specific PCR/Southern blot assay for detection of bovine herpesvirus 4 in calves infected experimentally." *Journal of Virological Methods* **83**(1-2): 169.

<http://www.sciencedirect.com/science/article/B6T96-3XVPG88-M/2/7c0dfd4d4d7210d5a3602dbff0b6e9e>

A PCR/Southern blot assay for detection of bovine herpesvirus 4 (BHV-4) in the background of bovine cellular DNA was developed. A BHV-4 specific sequence within the gene coding for the glycoprotein B (gB) was selected for primer sequences to guarantee the specificity of the assay. With a detection limit of six molecules BHV-4 DNA in the background of 1 [mu]g of cellular DNA (equals about 150000 bovine cells) this PCR/Southern blot assay represents a highly sensitive method for detection of BHV-4 DNA. At low concentrations of BHV-4 genomes, this assay also allows to estimate the copy number of BHV-4: a distinction between fewer than 6, 6-59 and more than 60 BHV-4 genomes/100 [mu]l DNA suspension was possible. Tissue and blood samples of two calves, infected experimentally with BHV-4 were examined for the prevalence of BHV-4 DNA 130 days post infection. Ten days before taking samples, one of the calves was immuno-suppressed with dexamethasone. In both calves, BHV-4 DNA was detected in the leucocyte fraction of the blood, and beyond that in lower quantities in the spleen and the kidney of the immuno-suppressed calf. It is assumed that a latent BHV-4 infection was activated after application of dexamethasone and that the leucocyte fraction of the blood represents one site of latency of BHV-4 in cattle.

Boni, J. and J. Schupbach (1993). "Primer extension analysis provides a sensitive tool for the identification of PCR-amplified DNA from HIV-1." *Journal of Virological Methods* **42**(2-3): 309.

<http://www.sciencedirect.com/science/article/B6T96-476RM72-2J/2/16688fe329aa2ea32a615cf7e04e8d9a>

Primer extension analysis was evaluated as a means to identify PCR-amplified DNA from HIV-1. Solution hybridization with radioactive labeled oligonucleotides followed by an extension reaction with Klenow fragment of Escherichia coli DNA polymerase I and subsequent separation on denaturing polyacrylamide gels reveals single stranded DNA products of the predicted size. The specificity of the reaction is further demonstrated by specific endonuclease digestion. The analysis is more sensitive than Southern blotting and about equally sensitive as Slot blot analysis when double-stranded DNA probes are used for hybridization. With end-labeled oligonucleotide probes, primer extension analysis proved an order of magnitude more sensitive than membrane hybridization. The analysis also allows quantitation of amplified DNA from 1 pg to about 1 ng of DNA product. Under the conditions described for amplification, primer extension analysis is capable of detecting a single HIV-1 plasmid DNA molecule in the presence of 1 [mu]g of total

DNA. 3'-end mismatching of the oligonucleotide probe does not result in a significantly altered detection limit. Primer extension analysis can also be carried out with at least three different PCR-amplified DNAs in the same reaction tube.

Boom, R., C. Sol, et al. (2000). "Detection and quantitation of human cytomegalovirus DNA in faeces." Journal of Virological Methods **84**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-3Y21VDG-1/2/9c147c239ca178c36e64f171c29e57b8>

The development and performance of a robust and sensitive PCR assay are described for the detection and quantitation of human cytomegalovirus DNA in human faecal specimens. In this assay, CMV DNA was purified by an optimised DNA extraction protocol together with internal control DNA that monitored both DNA extraction efficiency and PCR efficiency. The lower detection limit of the assay was reached at about 100 CMV particles per ml of (25-50%) faecal suspension. CMV DNA could be quantitated in the range of about 300-100000 molecules per ml of faecal suspension. CMV DNA loads obtained in clinical faeces specimens suggest that the assay can be used to monitor the efficacy of antiviral treatment. Reconstruction experiments that monitored the efficiency of DNA extraction of a preliminary DNA extraction protocol, showed low DNA yields for 9% of the specimens (n=78). In all cases, low DNA extraction efficiency seemed to be due to a component present in faeces that prevented DNA binding to silica particles, presumably by competitive binding. Choosing the right ratio of silica particles to faeces specimen solved this problem. Similarly, reconstruction experiments showed that the strong PCR inhibition that was observed in 8% of the specimens could effectively be relieved by the inclusion of [alpha]-casein in the PCR mixtures.

Boonham, N., L. G. Perez, et al. (2004). "Development of a real-time RT-PCR assay for the detection of Potato spindle tuber viroid." Journal of Virological Methods **116**(2): 139.

<http://www.sciencedirect.com/science/article/B6T96-4B958S0-1/2/960177b13ab6d627eae729d0be24bf0>

Potato spindle tuber viroid (PSTVd) is a quarantine pathogen in the European Union and causes damaging diseases of solanaceous crops. Under the EU Plant Health directive 2000/29/EC, countries must have the ability to detect and identify accurately and rapidly the introduction of harmful organisms in plants or plant products; furthermore, if the quarantine pathogen is found, be able to survey extensively for it. In this respect, PSTVd poses an interesting technical problem, since its RNA does not code for any proteins and thus any diagnostic method must be based on the detection of the RNA and be suitable for scaling up to testing large sample numbers. With this in mind a one-tube real-time RT-PCR assay based on TaqMan(TM) chemistry was developed. Investigations were carried out into various aspects of the assay relevant to the efficient amplification of targets that have a significant amount of secondary structure such as viroids. Thus comparisons were made of reverse transcription temperature, concentration and type of reverse transcriptase, RNA denaturation, sample purity and single versus two-tube reaction format. The assay developed was shown to be able to detect a wide range of isolates of PSTVd and in comparison with a chemi-luminescent hybridisation system was shown to be 1000-fold more sensitive. A further significant advantage of this assay format compared with hybridisation is that it is suitable for scaling up to large sample numbers using robotic liquid handling systems.

Bootman, J. S. and P. A. Kitchin (1992). "An international collaborative study to assess a set of reference reagents for HIV-1 PCR." Journal of Virological Methods **37**(1): 23.

<http://www.sciencedirect.com/science/article/B6T96-476F5XR-52/2/e431ef2b94b8d76f1b0e7033094e40ba>

An international collaborative study was performed to evaluate a set of PCR reference reagents for HIV diagnosis. Twenty-six laboratories from 9 countries analysed a proficiency panel of 10 coded DNA samples using the PCR reference reagents and protocols. For comparison, these coded samples were then assessed using a laboratory's own 'in-house' reagents and methodologies. The objectives of the study were: (i) to assess inter-laboratory variation of PCR sensitivity, (ii) to evaluate the DNA 'carryover' problem and frequency of false negative results and (iii) to examine the utility of the complete set of reagents and templates to act as reference preparations for HIV PCR. Using the reference reagents, 46% of laboratories reported no false positive results in any of their assays of the negative controls. The remaining laboratories all reported a false positive result(s) in at least one assay. The overall false positive result rate for the study was 9.3%. In contrast, an overall false negative result rate of 7.4% was observed, with some laboratories recording negative results even for samples containing 10000 molecules of target DNA. The level of absolute sensitivity may be assessed accurately only from the 12 laboratories that obtained no false positive results. All 12 laboratories detected the sample containing 10 molecules of template DNA and 9 out of the 12 laboratories detected the sample containing 1 molecule. This is in close agreement with the theoretical detection rate based on a statistical probability model for the detection of a single molecule. These characterised reference reagents were at least as sensitive as any of the 'in-house' reagents and methodologies applied, including nested PCR. The complete set of characterised reference reagents is now available for quality control assessment of HIV-1 PCR from the MRC ADP.

Boriskin, Y. S., J. C. Booth, et al. (1993). "Rapid detection of mumps virus by the polymerase chain reaction." Journal of Virological Methods **42**(1): 23.

<http://www.sciencedirect.com/science/article/B6T96-47YGSVX-4/2/03c0453462ef9d8a8a4d7e2087948693>

A procedure for detecting mumps virus in under 48 h was developed using the PCR. The sensitivity of the PCR amplification reaction and of the detection of the PCR product was significantly improved by: (i) enriching for viral template RNAs by overnight culture of the virus in Vero cells and (ii) substitution of polyacrylamide gel analysis for agarose gel electrophoresis. The technique was capable of detecting 1-20 infectious units of virus or an equivalent of 1-10 pg of mumps virus-specific plasmid DNA.

Briddon, R. W., A. G. Prescott, et al. (1993). "Rapid production of full-length, infectious geminivirus clones by abutting primer PCR (AbP-PCR)." Journal of Virological Methods **43**(1): 7.

<http://www.sciencedirect.com/science/article/B6T96-476F666-8K/2/68fb7c8742f2e6189b54c24e8d228262>

The application of the polymerase chain reaction (PCR) method of DNA amplification for the isolation of full-length, infectious clones of geminiviruses is described. Non-overlapping, abutting 20-mer oligonucleotide primers were used to produce a linear product from the circular geminivirus genomic template. Clones of African cassava mosaic virus (ACMV) DNA A, obtained by this method, were infectious following mechanical inoculation (in the presence of ACMV DNA

B) onto *Nicotiana benthamiana*. Normal ACMV symptoms resulted and typical geminate viral particles were detected by electron microscopy. The use of PCR for the detection and production of full-length, infectious geminivirus clones is discussed.

Bruni, R., C. Argentini, et al. (1995). "A PCR-based strategy for rapid mapping of hepadnavirus integrated sequences in hepatocellular carcinomas." Journal of Virological Methods **52**(3): 347.

<http://www.sciencedirect.com/science/article/B6T96-3YXC14C-C/2/5aef364fd8afd7ef3fce0500c4187b0a>

A methodology based on polymerase chain reaction (PCR) and restriction analysis for rapid mapping of woodchuck hepatitis virus (WHV) integrations in hepatocellular carcinoma (HCC) tissues is described. Conventional PCR with viral primer pairs is not suitable for mapping WHV-integrated regions because the presence of minimum amounts of non-integrated (PCR amplifiable) WHV genome and replicative intermediates cannot be excluded. The first relevant part of the strategy is the identification of the cellular sequences flanking the WHV integration in order to select one (or more) integration-specific primer. The cellular flanking sequence can be rapidly obtained by means of inverse-PCR amplification of the viral/cellular junction and sequencing of the product. Mapping of the integrated regions is carried out by fixed flanking primer PCR (FFP-PCR) using the cellular primer as a 'fixed' primer in PCR in association with each of an available set of WHV primers. Amplification of episomal WHV sequences is thus avoided. PCR products can also undergo restriction analysis. PCR-positive viral primers and specific WHV restriction sites are assembled into a map, based on the size and restriction pattern of the PCR products. The results of WHV integration mapping in a woodchuck HCC are described.

Cameron-Wilson, C. L., P. Muir, et al. (2003). "Evaluation of a line probe assay for identification of hepatitis B virus precore variants in serum from chronic hepatitis B carriers." Journal of Virological Methods **114**(1): 97.

<http://www.sciencedirect.com/science/article/B6T96-49SWFWP-7/2/bde013aadafe321e685e3e429fb19b76>

A prototype line probe assay (LiPA) for identifying hepatitis B virus (HBV) precore variants (INNO-LiPA HBV precore) was evaluated using a panel of 50 sera from 46 patients with HBV infection. The assay detected sequence variations detected commonly in the precore promoter region and in amino acid codons 28 and 29 of the precore gene. There was strong agreement between INNO-LiPA HBV precore results and those of a codon 28 point mutation assay (PMA), with identical results obtained in 40 of 43 sera (93%) typeable by both assays (kappa coefficient ([kappa])=0.90). In addition, the precore codon 29 sequence identified by the INNO-LiPA HBV precore was confirmed by nucleotide sequencing in all seven samples analysed. However, the INNO-LiPA HBV precore identified precore promoter sequences much less efficiently. The prototype assay could identify codon 28/29 sequences from as little as 10 HBV genome equivalents in 10 [μl] serum, and in experiments using artificially prepared mixtures of variants could identify a minor component constituting 2.5% of the total viral DNA population. The INNO-LiPA HBV precore was also straightforward technically and rapid, and is therefore likely to be useful for epidemiological investigations into the prevalence, distribution and clinical significance of HBV precore variants.

Casas, I., A. Tenorio, et al. (1997). "Detection of enteroviral RNA and specific DNA of herpesviruses by multiplex genome amplification." Journal of Virological Methods **66**(1): 39.

<http://www.sciencedirect.com/science/article/B6T96-3RYCMYM-18/2/a8b89a2b6019a196e061ff4c236aae9a>

A reverse transcription (RT) multiplex polymerase chain reaction (PCR) assay was developed to allow rapid, sensitive and simultaneous detection of enteroviral RNA and herpesviral DNA specific sequences in a single tube. The method involves a reverse transcription step followed by a multiplex nested PCR in which the combination of primers amplifies cDNA from enteroviruses and specific herpesviruses DNA. Nested amplification utilises primers designed to anneal into the amplification product from the first reaction. Individual viruses were then detected and differentiated by the size of their PCR products determined using ethidium bromide stained agarose gels. To exclude false negatives due to sample inhibitors an internal amplification control, a cloned fragment of DNA from Pseudorabies virus (PRV DNA) was included in the reaction mixture. Detection levels between 0.01 and 0.001 TCID₅₀ of prototype strains of Polio and Coxsackie type B viruses and between 1 and 100 molecules of cloned-DNA of herpesviruses prototype strains were achieved. The RT multiplex PCR method proved capable of detecting enteroviral RNA or herpesviral DNA in cerebro spinal fluid (CSF) samples from patients with aetiologically well characterized encephalitis or aseptic meningitis.

Chatellard, P., R. Sahli, et al. (1998). "Single tube competitive PCR for quantitation of CMV DNA in the blood of HIV+ and solid organ transplant patients." Journal of Virological Methods **71**(2): 137.

<http://www.sciencedirect.com/science/article/B6T96-3VCVDKK-1/2/b46f708cdced2d2252040882fee76527>

Cytomegalovirus (CMV) infection is a major cause of morbidity and mortality in transplant and HIV-infected patients. However, CMV can also cause asymptomatic infection. An elevated blood viral load as assessed by various methods appears to be a predictor for symptomatic infections, and can be used to identify patients at the highest risk of developing CMV disease. We developed a single tube competitive quantitative PCR assay for CMV DNA, using as a competitor a plasmid carrying the target sequence for amplification with an internal deletion. The analysis of data from repeated extractions and amplifications of samples showed that the coefficient of variation of the assay was typically less than 20%. Clinical samples from 14 HIV-infected and 13 solid organ transplant patients were analyzed. Widely varying CMV DNA levels were found in leukocytes, with a positive correlation with the measure of infectivity in the leukocytes by quantitative culture on fibroblasts. The highest CMV DNA content in leukocytes was found in two patients with presumptive CMV disease. In HIV patients, the amount of DNA in leukocytes was much larger than in solid organ transplant recipients, when standardized for infectivity. Although based on a very limited number of patients, this observation probably points to a difference in the biology of CMV infection in these two categories of susceptible individuals. CMV DNA was also found in the plasma of some of the patients with a high CMV DNA leukocyte load. The present test should be useful for identifying patients at high risk of developing CMV disease, for monitoring therapeutic efficacy of antiviral regimens and to improve the understanding the pathogenesis of CMV infection.

Chimside, E. D. and W. J. M. Spaan (1990). "Reverse transcription and cDNA amplification by the polymerase chain reaction of equine arteritis virus (EAV)." Journal of Virological Methods **30**(2): 133.

<http://www.sciencedirect.com/science/article/B6T96-476KWJH-34/2/c882ab4e649025070a2e728af800f2c8>

A technique is described for the amplification and specific identification of equine arteritis virus (EAV) nucleotide sequences. The polymerase chain reaction (PCR) was evaluated initially by amplification of cloned virus specific cDNA sequences prior to amplification of single-stranded (ss) cDNA produced by reverse transcription (RT) of viral genomic RNA. Three separate primer pairs were used for RT/PCR of EAV genomic RNA, each pair producing only one band in agarose gels of the predicted size from the genomic nucleotide sequence. The viral origin of cDNA products was confirmed by hybridisation analysis with EAV-specific probes. RT/PCR analysis of clinical material indicates the methodology is sensitive enough to detect 600 pfu/ml EAV in seminal plasma.

Chin Yuan, C., W. Miley, et al. (2001). "A quantification of human cells using an ERV-3 real time PCR assay." Journal of Virological Methods **91**(2): 109.

<http://www.sciencedirect.com/science/article/B6T96-426XYG8-2/2/c6f338eb172e5c82ee0b71a1554d9fde>

A novel approach to quantifying human cells using a real time PCR assay was developed. The target sequence used in the assay is a 135 bp segment within the unique 1.7 kb Hind III / Pst I fragment of the ERV-3 envelope gene. ERV-3 is a full-length human endogenous retrovirus present in known copy number in all human cells. The detection range of ERV-3 by real time PCR is from 10⁶ to 10¹. The precision described, sensitivity and specificity of the assay indicate that the ERV-3 sequence is an accurate cell quantitation marker. The quantitative ERV-3 assay enables simple, fast, and reproducible detection and quantitation of the cell number. The assay can be used to determine the sample DNA conditions and also it can be used to adjust the quantitative DNA measurements of other target gene assays relative to the number of cell equivalents.

Contorni, M. and P. Leoncini (1993). "Typing of human papillomavirus DNAs by restriction endonuclease mapping of the PCR products." Journal of Virological Methods **41**(1): 29.

<http://www.sciencedirect.com/science/article/B6T96-476RMYJ-6C/2/8e2abca7118a98dc596152c434d950f0>

The polymerase chain reaction (PCR) for the diagnosis of human papillomavirus (HPV) infections, and in particular for the study of cervical HPV-associated lesions, is used widely. We identified a novel set of universal primers that are able to amplify a fragment spanning the E1 open reading frame (ORF) from different mucosotropic HPV types. A restriction endonuclease digestion of the amplified products is suggested for accurate typing. In particular, AluI digestion of the amplified fragments yields a distinctive fragment pattern for each 'high-risk' (16, 18, 31 and 33) HPV sequence, thus distinguishing them from 'low-risk' (6b and 11) HPV sequences.

Davidson, I. and M. Malkinson (1996). "A non-radioactive method for identifying enzyme-amplified products of the reticuloendotheliosis proviral env and LTR genes using psoralen-biotin labelled probes." Journal of Virological Methods **59**(1-2): 113.

<http://www.sciencedirect.com/science/article/B6T96-3VYV049->

V/2/53bd806cd3e82f6562a721458a51bdaf

A novel polymerase chain reaction (PCR) system based on the env gene of reticuloendotheliosis virus (REV) strain REV-A for the detection of proviral DNA is described. The designed PCR product of 807 bp was identified using an internal probe of 278 bp produced by nested PCR from REV-infected DNA CEF. The env-gene PCR was then compared with the previously described PCR for proviral REV-long terminal repeat and the PCR product served also as the probe. The probes were labelled with the psoralen-biotin system by photoactivation and the southern blot hybridization signal was detected colorimetrically. The advantages of using a non-radioactive means of probe labelling were demonstrated clearly in that study, as well as the effective labeling of probes with psoralen-biotin and the simple colorimetric method of detection. The env-gene PCR detected all eleven REV strains used in the study. These included three REV prototype strains and eight Israeli REV isolates. Both PCR systems had similar levels of sensitivity.

Desario, C., N. Decaro, et al. "Canine parvovirus infection: Which diagnostic test for virus?" Journal of Virological Methods **In Press, Corrected Proof**
<http://www.sciencedirect.com/science/article/B6T96-4FRHD09-1/2/6391ff1332d2ceb835611b30a558f7db>

Five laboratory tests for diagnosis of canine parvovirus type 2 (CPV-2) infection were employed to test 89 faecal samples collected from dogs with diarrhoea. The tests analysed were immunochromatography (IC), haemagglutination (HA), virus isolation (VI), conventional and real-time PCR. IC, HA, VI and conventional or real-time PCR were able, respectively, to detect CPV-2 antigen or nucleic acid in 41, 50, 54, 68 and 73 of the samples. The best correlation was found between conventional and real-time PCR, with an overall agreement of 94.38%. Sixty-eight samples that tested positive by HA, VI or conventional PCR were subjected to antigenic and/or genetic analyses of the CPV-2 strains by monoclonal antibody (MAb), restriction fragment-length polymorphism (RFLP) and/or sequence analyses. In sum, out of the 68 strains analysed, 26 were characterised as CPV-2a, 18 as CPV-2b and 24 as a CPV-2 Glu-426 mutant recently identified in Italy.

Dewhurst-Maridor, G., V. Simonet, et al. (2004). "Development of a quantitative TaqMan RT-PCR for respiratory syncytial virus." Journal of Virological Methods **120**(1): 41.

<http://www.sciencedirect.com/science/article/B6T96-4CHGDDP-1/2/3ff11d621d2f4d6514dcece3411c97ec>

Respiratory syncytial virus (RSV) is a ubiquitous RNA virus of the family Paramyxoviridae that may interfere with graft tolerance and with other interstitial lung diseases. The low viral titre observed in the immunodeficient transplanted patients requires a highly sensitive detection method. Although different tests already exist for the detection of RSV, reverse transcription-polymerase chain reaction (RT-PCR) has been shown to have the best sensitivity. In this study, a SYBR Green assay was established for the detection of RSV A and RSV B in a common screening test, and two quantitative TaqMan RT-PCRs were developed to quantify both RSV subgroups separately. Standard dilutions obtained from RSV cell infections were included in each test, and the assay was normalised using a housekeeping gene. RSV was found in 16% of the transplanted patients tested. The quantitative TaqMan assay is fast, reproducible, specific and very sensitive, and could facilitate considerably the detection of RSV virus. This would in-turn facilitate studies on the role of RSV in graft rejection.

A simple reverse transcription-polymerase chain reaction (RT-PCR) procedure for the detection of GB virus C (GBV-C) RNA in serum or plasma is described. In this method, total nucleic acid, extracted from a small volume of human plasma, is reverse transcribed using random hexamers. An aliquot of cDNA is then utilized in PCR employing GBV-C specific primers designed to highly conserved regions of the 5'nontranslated region (NTR). For additional sensitivity, a second round

of nested amplification is performed. Reactions are analyzed on an agarose gel and samples showing an ethidium bromide stained band of the appropriate size in the first and second amplification, or in the second amplification only, are designated to be positive. This protocol allows for the rapid and sensitive detection of GBV-C infection in human plasma or serum.

Erker, J. C., S. M. Desai, et al. (1999). "Rapid detection of Hepatitis E virus RNA by reverse transcription-polymerase chain reaction using universal oligonucleotide primers." Journal of Virological Methods **81**(1-2): 109.

<http://www.sciencedirect.com/science/article/B6T96-3XMPJNX-G/2/6e14405581559722cb6294105d75e4ab>

A rapid reverse transcription-polymerase chain reaction (RT-PCR) procedure for the detection of Hepatitis E virus (HEV) RNA in serum is described. Total nucleic acids are extracted from a small volume of human serum and reverse transcribed using random hexamers. An aliquot of cDNA is then utilized in nested PCR employing degenerate HEV consensus primers. These primers are designed to sequences conserved between the Burma, Mexico, and US HEV strains, generating amplicons within each of the three open reading frames. Reactions are analyzed by agarose gel electrophoresis and samples showing an ethidium bromide stained band of the appropriate size in the first and second amplification, or in the second amplification only, are designated as positive. This protocol allows for the rapid and sensitive detection of HEV infection in human serum.

Eun, A. J.-C., M.-L. Seoh, et al. (2000). "Simultaneous quantitation of two orchid viruses by the TaqMan(R) real-time RT-PCR." Journal of Virological Methods **87**(1-2): 151.

<http://www.sciencedirect.com/science/article/B6T96-40GJ2JM-J/2/4f08efce75bb16c36484b88e0b6ac30a>

Simultaneous quantitation of two orchid viruses, cymbidium mosaic potexvirus (CymMV) and odontoglossum ringspot tobamovirus (ORSV), were carried out using the TaqMan(R) real-time RT-PCR, a novel detection technique that combines RT-PCR with the power of fluorescent detection. Four TaqMan(R) probes were synthesized, targeting at the RNA-dependent RNA polymerase (RdRp) and coat protein (CP) genes of both viruses. The reporter dye FAM (6-carboxyfluorescein) was used to label the 5' terminus of probes specific to CymMV, while TET (tetrachloro-6-carboxyfluorescein) was used for the ORSV probes. TAMRA (6-carboxy-tetramethyl-rhodamine), which was attached at the 3' terminus of each probe, was used as the universal quencher. With increasing amounts of standard RNA templates, the respective threshold cycle (CT) values were determined and a linear relationship was established between these CT values and the logarithm of initial template amounts. The amounts of starting templates in mixed-infected *Oncidium* flowers and leaves were estimated from the standard curves. As little as 104 copies or 5 fg each of CymMV and ORSV could be detected simultaneously with either the RdRp or CP gene as the target. This system offers a sensitive, high throughput and rapid method for plant virus detection.

Evans, P. C., J. Gray, et al. (1998). "Optimisation of the polymerase chain reaction and dot-blot hybridisation for detecting cytomegalovirus DNA in urine: comparison with detection of early antigen fluorescent foci and culture." Journal of Virological Methods **73**(1): 41.

<http://www.sciencedirect.com/science/article/B6T96-3T2PCND-5/2/d3c00709a679180bccdcf47c6b8e4730>

Rapid, sensitive and specific assays are required for the diagnosis of CMV infection following transplantation. We describe our experience in developing assays for detecting CMV in urine. Conventional preparation of probes cloned after amplification in *E. coli* led to contamination with *E. coli* nucleic acids; these hybridised to *E. coli* DNA present in urine and produced false positive results. Two CMV probes (Hind III and gL) hybridised to human DNA despite high stringency; these probes were thus unsuitable for detecting viral nucleic acids in clinical samples. A PCR derived probe from the immediate early gene of CMV detected dot-blotted CMV DNA specifically. Optimal preparation of urine for detection of CMV DNA was as follows; four freeze/thaw cycles and ultracentrifugation before in vitro proteinase K/SDS treatment, phenol:chloroform extraction, heat denaturation and direct application onto a nylon membrane. However, dot-blot hybridisation was a poor test for CMV in urine; it had low sensitivity and specificity compared with virus isolation and DEAFF. Single round PCR of a 293bp region of CMV DNA was sensitive and specific to CMV targets. However, undiluted urine contained PCR inhibitors that could only be partly removed by using PEG precipitation. PCR of CMV DNA from urine was specific but was insensitive compared to conventional culture and DEAFF. A significant proportion of urine samples were toxic in conventional culture and DEAFF tests but, PCR of CMV DNA from urine is insensitive and despite its specificity is unlikely to be advantageous in clinical practice even when DEAFF or culture prove unreliable.

Fabre, F., C. Kervarrec, et al. (2003). "Improvement of Barley yellow dwarf virus-PAV detection in single aphids using a fluorescent real time RT-PCR." *Journal of Virological Methods* **110**(1): 51.

<http://www.sciencedirect.com/science/article/B6T96-48CNW0D-1/2/439cbec68940d7e63b490ad51961bc19>

One of the major factors determining the incidence of Barley yellow dwarf virus (BYDV) on autumn-sown cereals is the viruliferous state of immigrant winged aphids. This variable is assessed routinely using the enzyme-linked immunosorbant assay (ELISA). However, the threshold for virus detection by ELISA can lead to false negative results for aphids carrying less than 106 particles. Although molecular detection techniques enabling the detection of lower virus quantities in samples are available, the relatively laborious sample preparation and data analysis have restricted their use in routine applications. A gel-free real-time one-step reverse transcription polymerase chain reaction (RT-PCR) protocol is described for specific detection and quantitation of BYDV-PAV, the most widespread BYDV species in Western Europe. This new assay, based on TaqMan(R) technology, detects and quantifies from 102 to 108 BYDV-PAV RNA copies. This test is 10 and 103 times more sensitive than the standard RT-PCR and ELISA assays published previously for BYDV-PAV detection and significantly improves virus detection in single aphids. Extraction of nucleic acids from aphids using either phenol/chloroform or chelatin resin-based protocols allow the use of pooled samples or of a small part (up to 1/1600th) of a single aphid extract for efficient BYDV-PAV detection.

Falcone, E., E. D'Amore, et al. (1997). "Rapid diagnosis of avian infectious bronchitis virus by the polymerase chain reaction." *Journal of Virological Methods* **64**(2): 125.

<http://www.sciencedirect.com/science/article/B6T96-3RJ9BMF-2/2/8f8a7aebc8132e8848af2ec6d2901c8c>

A simple, sensitive and specific polymerase chain reaction (PCR) procedure was developed in

order to detect infectious bronchitis virus (IBV) directly in tissue samples. Viral RNA was extracted from allantoic fluids and cell cultures infected experimentally with different strains of IBV and from tissues of naturally infected birds. Viral RNA was then amplified and identified by a nested RT-PCR assay using two sets of primers flanking a well-conserved region of the nucleocapsid gene. The selected IBV nucleocapsid sequence was detected successfully by simple direct electrophoresis of amplified material.

Fang, G., G. Zhu, et al. (1998). "Minimizing DNA recombination during long RT-PCR." Journal of Virological Methods **76**(1-2): 139.

<http://www.sciencedirect.com/science/article/B6T96-3V5V5SV-H/2/7c71936eb89a8bdc4722309fe5e2d2b>

Recent developments have made it possible to reverse transcribe RNA and amplify cDNA molecules of >10 kb in length, including the HIV-1 genome. To use long reverse transcription combined with polymerase chain reaction (RT-PCR) to best advantage, it is necessary to determine the frequency of recombination during the combined procedure and then take steps to reduce it. We investigated the requirements for minimizing DNA recombination during long RT-PCR of HIV-1 by experimenting with three different aspects of the procedure: conditions for RT, conditions for PCR, and the molar ratios of different templates. We used two distinct HIV-1 strains as templates and strain-specific probes to detect recombination. The data showed that strategies aimed at completing DNA strand synthesis and the addition of proofreading function to the PCR were most effective in reducing recombination during the combined procedure. This study demonstrated that by adjusting reaction conditions, the recombination frequency during RT-PCR can be controlled and greatly reduced.

Feucht, H. H., B. Zollner, et al. (1995). "Comparison of conventional autoradiography with a new DNA enzyme immunoassay for the detection of hepatitis C virus-polymerase chain reaction amplification products." Journal of Virological Methods **55**(1): 105.

<http://www.sciencedirect.com/science/article/B6T96-3YYTF0W-19/2/ae45973e875d9693bcf16d31f7f60463>

The detection of HCV-PCR amplification products by DNA enzyme immunoassay (DEIA) was compared with conventional hybridization carried out with a ³²P-labelled oligonucleotide probe. The detection limit of both methods was shown to be between 100 pg and 1 ng of amplicon. All serum samples of 40 HCV-seropositive patients were positive after PCR in autoradiography, but only 38 with the DEIA technique (sensitivity 95%). There were no false-positive reactions by either method. The advantage of the DEIA method was the fast and non-radioactive detection of HCV amplicons. DEIA combines the specificity of the hybridization event with the speed of an ELISA procedure and is suitable for HCV-PCR.

Formiga-Cruz, M., A. Hundesa, et al. (2005). "Nested multiplex PCR assay for detection of human enteric viruses in shellfish and sewage." Journal of Virological Methods **125**(2): 111.

<http://www.sciencedirect.com/science/article/B6T96-4FFH1XG-2/2/3f8dd23d017b88125eccc9122d6e4fc>

Environmental samples and contaminated shellfish present frequently low concentrations of more

than one viral species. For this reason, a nested multiplex RT-PCR was developed for the detection of adenoviruses, enteroviruses and hepatitis A viruses in different environmental samples such as urban sewage and shellfish. This assay will save time and cost for detection of these enteric viruses with a smaller sample volume, which otherwise can be a limiting factor in routine analysis. The limit of detection was approximately 1 copy for adenovirus and 10 copies for enterovirus and hepatitis A virus per PCR reaction using titrated cell-cultured viruses as template material. In shellfish and environmental samples, this multiplex PCR was optimized to detect all three viruses simultaneously when the concentration of each virus was equal or lower than 1000 copies per PCR reaction. This is the level found predominantly in the environment and in shellfish when the numbers of fecal bacterial and phage indicators are low. The detection of human adenoviruses by PCR has been suggested as a molecular index of fecal contamination of human origin in the environment and food and the multiplex assay developed may be a tool for evaluating the presence of viral contamination in shellfish and water and to expand microbiological control to include viral markers.

Forslund, O., H. Ly, et al. (2003). "Improved detection of cutaneous human papillomavirus DNA by single tube nested 'hanging droplet' PCR." Journal of Virological Methods **110**(2): 129.

<http://www.sciencedirect.com/science/article/B6T96-48KMMH5-1/2/21b0818017e2050923d968ba9fd138bf>

A single tube nested 'hanging droplet' PCR was developed for detection of cutaneous human papillomavirus (HPV) DNA of the phylogenetic group B1. The nested PCR was compared with a single round PCR method by testing 56 fresh biopsies from Australian skin tumour patients. HPV DNA was detected in 64% (36/56) of the biopsies by nested PCR and in 30% (17/56) by single round PCR (PP=0.003], squamous cell carcinoma [43% (7/16) vs. 25% (4/16)] and in solar keratosis [93% (13/14) vs. 57% (8/14); P=0.038]. The nested PCR and the single round PCR system detected 26 and 11 different HPV types/putative types/subtypes, respectively. Multiple types were found in eight samples by the nested PCR and two samples by single round PCR. The nested HPV PCR is more sensitive and capable of amplifying a broad spectrum of HPV types from skin tumours, but further improvements are needed before all HPV infections in skin can be detected by a single assay.

Forsman, A., D. Uzameckis, et al. (2003). "Single-tube nested quantitative PCR: a rational and sensitive technique for detection of retroviral DNA. Application to RERV-H/HRV-5 and confirmation of its rabbit origin." Journal of Virological Methods **111**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-48NKTJ2-2/2/e7668d7aed4a8cd8be75c568f8c0011f>

It was reported earlier that a few patients suffering from non-Hodgkin's lymphoma had low amounts of DNA from the so-called fifth human exogenous retrovirus, HRV-5. A sensitive and rational method for large-scale screening for HRV-5 DNA was therefore developed. It is a single-tube nested quantitative PCR (stnQPCR), which uses two functionally isolated primer pairs and one probe target distinct from related endogenous retroviral sequences, yet encompassing known HRV-5 variation, allowing optimal use of sequence conservation. DNA from lymphoma, myeloma, and follicular dendritic cell lines was tested for HRV-5 positivity, as was DNA from whole blood of blood donors, non-Hodgkin's lymphoma and systemic lupus erythematosus patients, as well as DNA from lymph node biopsies of rheumatoid arthritis patients with lymphoma. One blood donor, one systemic lupus erythematosus patient, two previously known positive non-Hodgkin's lymphoma patients, and one rheumatoid arthritis lymphoma patient, came out positive. They had 24, 2, 148, 480 and 30 proviral copies per [mu]g of DNA from PBMC or lymphoma tissue,

respectively. During the completion of this work it was reported that HRV-5 is a rabbit endogenous retrovirus (RERV-H), and that HRV-5 positivity was due to presence of rabbit DNA. DNA from six RERV-H/HRV-5 positive samples was therefore retested. Three also contained rabbit mitochondrial DNA. A search for HRV-5 antibodies using synthetic peptides was negative in sera from three RERV-H/HRV-5 positive individuals, as well as in 144 other sera, according with a noninfectious origin of the RERV-H/HRV-5 DNA in human samples. A search for possible sources of rabbit DNA contamination was negative. Methods for prevention of PCR contamination were strictly adhered to. Three samples from RERV-H/HRV-5 positive individuals positive at the Uppsala laboratory were retested at one or two other laboratories, and all three were positive. Two other samples, which were positive in the Riga laboratory, were tested also in London and also found positive. One non-Hodgkin's lymphoma patient was RERV-H/HRV-5 positive in four consecutive samples, showing that positivity was a property of that patient. It is concluded that the stnQPCR developed to detect and quantify minute amounts of RERV-H/HRV-5 DNA is a principle which can be applied widely and HRV-5 is a RERV-H. Its presence in a few human blood samples could not be explained.

Forsyth, M. A., S. Parida, et al. (2003). "Rinderpest virus lineage differentiation using RT-PCR and SNAP-ELISA." Journal of Virological Methods **107**(1): 29.

<http://www.sciencedirect.com/science/article/B6T96-474DS2H-2/2/2d11968dd2eeb7be200157d2e733cbdb>

An RT-PCR/ELISA system has been developed that detects and differentiates Rinderpest virus (RPV) from the other closely related morbillivirus of ruminants, Peste des petits Ruminants virus (PPRV). In addition, using lineage specific probes, it is possible to determine whether the virus sample is wild-type or vaccine, and the likely origin of the outbreak if it is wild-type. It involves carrying out a RT-PCR with one digoxigenin (Dig)-labelled primer followed by a hybridisation step with a virus-specific, biotin-labelled, probe. The hybridisation step is carried out in an ELISA format on a streptavidin-coated plate. The DIG-labelled products are detected using a specific anti-DIG monoclonal antibody and an anti-mouse horseradish peroxidase conjugate. The hybridisation step replaces nucleotide sequencing or nested PCR for confirmation of the identity of DNA product. The assay is fast and easy to carry out and can give semi-quantitative estimates of the virus content of samples.

Foster, T. P., G. V. Rybachuk, et al. (1998). "Expression of the enhanced green fluorescent protein by herpes simplex virus type 1 (HSV-1) as an in vitro or in vivo marker for virus entry and replication." Journal of Virological Methods **75**(2): 151.

<http://www.sciencedirect.com/science/article/B6T96-3V5F5S6-3/2/cdcbe9ca99cc3181143189332fa1b1ef>

Glycoprotein K (gK) is involved in membrane fusion phenomena during infectious virus production and egress and is an important determinant for neurovirulence. To assess better the in vitro and in vivo roles of gK in virus replication, a recombinant virus was constructed expressing an engineered enhanced green fluorescent protein (EGFP) under the control of the human cytomegalovirus immediate early gene promoter (HCMV-IEP) inserted in place of the gK gene. The EGFP gene insertion was confirmed by diagnostic polymerase chain reaction (PCR), and the presence of the EGFP protein was detected by western immunoblot analysis using anti-GFP monoclonal antibody. Fluorescence microscopy revealed that virus infected cells emitted bright fluorescence when examined using filters for fluorescein. Fluorescence emission was detected as early as 4 h post-infection. Fluorescence intensity increased over time and was stable at late times after infection at which point viral plaques continued to emit bright green fluorescence. The

amount of fluorescence emitted by virus infected Vero cells was monitored by fluorescence cytometry using a FACS cytometer. At an MOI of 3, all infected cells emitted strong green fluorescence as quantified by cytometry at 48 h post-infection. The [Delta]gK-EGFP expressing recombinant virus will enable the determination of the role of gK in virus entry and egress as well as the role of gK in the molecular pathogenesis of herpes simplex virus type 1 (HSV-1).

Fuessel Haws, A. L., Q. He, et al. (2004). "Nested PCR with the PGMY09/11 and GP5+/6+ primer sets improves detection of HPV DNA in cervical samples." Journal of Virological Methods **122**(1): 87.

<http://www.sciencedirect.com/science/article/B6T96-4DDTMGF-1/2/ac059cf432fa0b44655c9edccf53a55e>

Based on epidemiological and research evidence, HPV has a causal role in cervical carcinogenesis. Several HPV detection methods exist to date; the most commonly used method for detection of genital HPVs consists of nested PCR using the MY09/11 and GP5+/6+ primer sets (MY/GP+). Recently, the PGMY09/11 primer set, a modified version of the MY09/11 primer set, was introduced for single PCR and was found to detect a wider range of HPV types. The next logical step was taken and the efficacy of nested PCR using the PGMY09/11 and GP5+/6+ primer sets (PGMY/GP+) to detect HPV in cervical samples was evaluated. In this comparative study, nested PCR using the novel PGMY/GP+ primer set combination was found to be more type sensitive than the nested PCR with the MY/GP+ primer sets, detecting a wider range of HPV types, low copy HPVs, and better characterizing samples infected with multiple strains of HPV. Standardization and use of the PGMY/GP+ PCR system could aid physicians in providing more efficient HPV screening and better treatment for patients.

Fujioka, S., H. Koide, et al. (1995). "Analysis of enterovirus genotypes using single-strand conformation polymorphisms of polymerase chain reaction products." Journal of Virological Methods **51**(2-3): 253.

<http://www.sciencedirect.com/science/article/B6T96-402KYYX-D/2/d910471a8c50421b04c3852185606e15>

Enterovirus genotypes were identified rapidly by reverse transcription-polymerase chain reaction (RT-PCR) followed by single-strand conformation polymorphism (SSCP) analysis. The primer pair was chosen from the highly conserved sequence at the 5' non-coding region of enterovirus genomes. RT-PCR amplified a 154 bp sequence in all samples from 14 serotypes of enteroviruses, including group A and B Coxsackie viruses, echoviruses and polioviruses. SSCP analysis of these products revealed different electrophoretic profiles. Thus, SSCP analysis will be useful for differentiating the genotypes of enteroviruses, and may be applicable for rapid diagnosis of enteroviral infection.

Gehring, H., K. Von der Helm, et al. (2003). "Development and evaluation of a phenotypic assay monitoring resistance formation to protease inhibitors in HIV-1-infected patients." Journal of Virological Methods **109**(2): 143.

<http://www.sciencedirect.com/science/article/B6T96-484VJJM-1/2/e41b6217f067fcd97d1cd3c98143f8f2>

A novel phenotypic assay, based on recombinant expression of the HIV-1-protease was

developed and evaluated; it monitors the formation of resistance to protease inhibitors. The HIV-1 protease-encoding region from the blood sample of patients was amplified, ligated into the expression vector pBD2, and recombinantly expressed in *Escherichia coli* TG1 cells. The resulting recombinant enzyme was purified by a newly developed one-step acid extraction protocol. The protease activity was determined in presence of five selected HIV protease inhibitors and the 50% inhibitory concentration (IC₅₀) to the respective protease inhibitors determined. The degree of resistance was expressed in terms of x-fold increase in IC₅₀ compared to the IC₅₀ value of an HIV-1 wild type protease preparation. The established test system showed a reproducible recombinant expression of each individual patients' HIV-1 protease population. Samples of nine clinically well characterised HIV-1-infected patients with varying degrees of resistance were analysed. There was a good correlation between clinical parameters and the results obtained by this phenotypic assay. For the majority of patients a blind genotypic analysis of the patients' protease domain revealed a fair correlation to the results of the phenotypic assay. In a minority of patients our phenotypic results diverged from the genotypic ones. This novel phenotypic assay can be carried out within 8-10 days, and offers a significant advantage in time to the current employed phenotypic tests.

Gibbs, A. and A. Mackenzie (1997). "A primer pair for amplifying part of the genome of all potyvirids by RT-PCR." *Journal of Virological Methods* **63**(1-2): 9.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-T/2/98d98dc0e4883bedac56c3fdd03157cf>

Sequence analysis was used to design a pair of degenerate oligonucleotide primers that amplified a 1.6-2.1 kbp fragment from the 3' end of the genome (virion protein gene and part of the NIb gene) of 17 species of the Potyviridae ('potyvirids'); 11 potyviruses, 2 bymoviruses, 2 macluraviruses, an ipomovirus and a rymovirus. The 'potyvirid primer 1' hybridizes to the 3' terminal poly-A region of the genome, and 'potyvirid primer 2' to the genomic region encoding the GNNSGQ-motif of the NIb protein. Database searches showed that the potyvirid 2 primer is specific for potyvirids. Associated analyses indicated that the published amino acid sequence of part of the wheat streak mosaic rymovirus NIb protein is probably incorrect in part.

Gibson, K. M., K. A. McLean, et al. (1991). "A simple and rapid method for detecting human immunodeficiency virus by PCR." *Journal of Virological Methods* **32**(2-3): 277.

<http://www.sciencedirect.com/science/article/B6T96-476KXFR-JG/2/fe551045ebfffc936ebbf04546eb4de>

A simple, sensitive and specific method using the polymerase chain reaction (PCR) for amplification of human immunodeficiency virus type 1 (HIV-1) is described. The method involves minimal manipulations. Peripheral blood mononuclear cells (PBMC) were prepared by a rapid Ficoll-Paque gradient method. Lymphocytes were lysed in PCR buffer containing Proteinase K and detergents, and subjected to amplification under stringent conditions, using two primer pairs. Amplified DNA sequences were hybridized with a 3'-end labelled probe, electrophoresed on agarose gels and visualised by ethidium bromide staining. Identification of amplified HIV-1 proviral DNA sequences was confirmed by autoradiography. HIV-1 sequences were amplified in all samples from 103 HIV-1 seropositive individuals, but not in 40 HIV-1 seronegative controls. The absence of contamination may be attributable in part to minimisation of manipulations before amplification.

Gough, K. C., W. Cockburn, et al. (1999). "Selection of phage-display peptides that bind to cucumber mosaic virus coat protein." Journal of Virological Methods **79**(2): 169.

<http://www.sciencedirect.com/science/article/B6T96-3WJDTS6-6/2/8d9b46546fa13509ce4d2304d087dacf>

Several discrete peptides that bind specifically to the coat protein of cucumber mosaic virus (CMV) were isolated from a diverse phage library displaying random nonapeptides on the major coat protein VIII. Enrichment was shown by polyclonal phage enzyme linked immunosorbent assay (ELISA) after three rounds of selection. Sequencing of the genes encoding 10 of these peptides revealed an absence of any conserved motifs, although nine of them contained a high proportion of proline residues. Some of the selected peptides were displayed at the N-terminus of thioredoxin and expressed in the cytoplasm of *Escherichia coli*. Both the phage-displayed and thioredoxin-fusion versions of the peptides could detect purified CMV and CMV present in crude leaf extracts from infected plants. By dot blot analysis, a thioredoxin-peptide fusion could readily detect as little as 5 ng of CMV. The peptides did not bind to other plant viruses. These peptides have been shown to be specific and highly sensitive tools in the detection of CMV and, as well as their diagnostic potential, they could form the basis for a novel disease resistance strategy.

Gouvea, V., S. J. Cohen, et al. (1997). "Identification of hepatitis E virus in clinical specimens: amplification of hydroxyapatite-purified virus RNA and restriction endonuclease analysis." Journal of Virological Methods **69**(1-2): 53.

<http://www.sciencedirect.com/science/article/B6T96-3S2BMBF-7/2/187546e9a6dc5b99c6e2ddc12dddb55e>

A multi-site nested reverse transcription and polymerase chain reaction (RT-PCR) followed by restriction endonuclease analysis (REA) was developed to identify hepatitis E virus (HEV) in clinical specimens. Four sets of primers were selected to amplify regions in the HEV genome supposed to encode the helicase, polymerase, and parts of the viral capsid protein. Digestion of the nested PCR products with *HinfI*, *HaeII*, *Avall*, *BglI*, *KpnI*, *SmaI*, or *EcoRI* generated readily recognizable profiles that confirm the HEV sequences and/or distinguish the unique Mexico genotype (our positive control) from all other isolates (Asian genotype). In addition, the hydroxyapatite (HA) adsorption method was compared to other adsorption and extraction methods widely used to purify viral RNA from clinical specimens for RT-PCR. All methods presented the same sensitivity of recovery of HEV RNA, but only the adsorption methods efficiently removed fecal enzymatic inhibitors. The HA method gave the best results and was the most economic in terms of time, cost, manipulations and reagents. The method was validated by screening a small number of serum and fecal specimens available from patients with acute non-A,B,C hepatitis in Nepal. HEV RNA was identified in half (5/11) of the fecal specimens obtained from patients with evidence of recent HEV infection, but in none of the 14 patients without a serological marker for hepatitis E.

Gouvea, V., N. Santos, et al. (1994). "Identification of Norwalk virus in artificially seeded shellfish and selected foods." Journal of Virological Methods **48**(2-3): 177.

<http://www.sciencedirect.com/science/article/B6T96-476F6FR-DM/2/5bb703002fee89b1144607dde0dbdb6>

A rotavirus dsRNA purification protocol was adapted to extract Norwalk ssRNA from artificially contaminated shellfish, and a sensitive reverse transcription-polymerase chain reaction assay for

Norwalk virus was devised to identify an estimated 20-200 genomic copies. The technique includes deproteinization with guanidinium isothiocyanate, adsorption of RNA to hydroxyapatite, and sequential precipitation with cetyltrimethylammonium bromide and ethanol. The protocol allows high recovery of viral RNA free of enzymatic inhibitors from oysters, clams, and a variety of food matrices. Norwalk virus sequences were copied and amplified by using primers selected from the polymerase gene. Digestion of the amplified products with restriction enzymes ensured the specificity of the test. This rapid and sensitive assay may significantly improve the prospect for the routine screening of the uncultivable Norwalk virus in food stuffs.

Grankvist, O., L. Walther, et al. (1996). "Nested PCR assays with novel primers yield greater sensitivity to Tanzanian HIV-1 samples than a commercial PCR detection kit." Journal of Virological Methods **62**(2): 131.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-H/2/64445824136310710ca8f94cbe9f017f>

To investigate the efficacy of the SK431/SK145 primer pair and two nested primer assays in amplifying African HIV-1 samples, a total of 35 Tanzanian PBMC samples were examined. These were assayed by two HIV-1 specific nested in-house PCR assays and a commercial HIV-1 PCR kit (GeneAmp™) using SK431/SK145 as the primer pair. One of the nested PCR assays has been evaluated previously (old assay), whereas the modified assay was constructed from the HIV-1 sequence alignment released in August 1993. The modified nested primer assay showed increased sensitivity in the gag and env regions compared to the old nested primer assay. However, both the old and the modified nested primer assays displayed higher sensitivity for the detection of Tanzanian HIV-1 proviruses than the GeneAmp™ assay. When two regions were used (gag and env) as targets for the amplification, the modified nested primer assay detected 97.1% (34/35) of the proteinase K lysed samples, compared to 68.6% (24/35) using the SK431/SK145 primer pair ($P < 0.01^{**}$). The results indicate that the SK431/SK145 primer pair may be less suitable when HIV-1 samples from Africa are analysed. The results also show that continuous modification of primer sequences can improve and maintain high sensitivity for the detection of highly divergent HIV-1 strains.

Gratzl, S., C. Moroni, et al. (1997). "Quantification of HIV-1 viral RNA and proviral DNA by isotopic competitive PCR." Journal of Virological Methods **66**(2): 269.

<http://www.sciencedirect.com/science/article/B6T96-3RYCMYM-8/2/c7a8302dd1ca779cfecce4db7bbba2c7>

A quantitative isotopic competitive PCR (icPCR) assay was established using ³²P-labeled primers targeting the HIV-1 gag gene followed by quantification using a phosphorimager. The detection limit varied from 3 to 10 molecules of DNA and 10 to 100 molecules of RNA per reaction. The icPCR quantification of HIV-1 DNA copies correlated well with the cell number of 8E5/LAV cells bearing a single provirus ($r^2 = 0.95$). Provirus quantification was applied to overnight infected donor PBMCs, thereby determining infectious virus titres in culture supernatants as a rapid alternative to limiting dilution culture. Parallel quantification of the HIV-1 RNA indicated the infectious virus fraction to be 0.3%. In 39 HIV-1-infected patients with clinical stages A ($n = 17$), B ($n = 15$), and C ($n = 7$), the HIV-1 RNA in the plasma was determined ranging from 100 to 90600 RNA copies/ml. The results of icPCR and a commercial assay (ROCHE Amplicor HIV-1 Monitor) correlated well ($r = 0.97$). In 13 additional patients, the plasma viral load per ml was compared with the proviral load per 10⁶ PBMC showing a viral excess of 10-1000-fold (mean of 85, $r = 0.7$, $P < 0.01$). It is concluded that icPCR is suitable for the measurement of proviral and viral load in experimental and clinical settings.

Gravitt, P. E., C. Peyton, et al. (2003). "Reproducibility of HPV 16 and HPV 18 viral load quantitation using TaqMan real-time PCR assays." Journal of Virological Methods **112**(1-2): 23.

<http://www.sciencedirect.com/science/article/B6T96-497RGSC-3/2/c55bd22df6d30913b5deec124ef5ed8f>

A reproducibility study was designed to assess within-assay, between-day, and interlaboratory variability of three real-time PCR assays targeting HPV 16, HPV 18, and the human glyceraldehyde-3-phosphate dehydrogenase (GAPDH) pseudogenes. Fifteen HPV 16 and fifteen HPV 18 cervical swab samples were amplified in triplicate by GAPDH and HPV 16 and by GAPDH and HPV 18 assays, respectively. All samples were amplified undiluted and at a 1:10 dilution on 2 separate days in the same laboratory, and the same samples were amplified in a separate laboratory. HPV 16 and HPV 18 normalized viral load is reported as the number of HPV genomes per 20000 GAPDH copies. The analytic specificity of the HPV 16 and 18 assays was 100 and 97%, respectively. The intraclass correlation coefficients (ICC) were 0.99, 0.97, and 0.98 for HPV 16, HPV 18, and GAPDH, respectively, indicating that the variability due to experimental error was very low. Ten-fold differences in viral load could be readily discriminated across a six order of magnitude dynamic range (ca. 5-5 x 10⁶ copies). Power of discrimination was increased at higher target concentrations (>5000 copies). The correlation of normalized HPV 16 and 18 viral load was high between the two laboratories (Spearman rho ([rho])=0.96 and 0.87, respectively). These HPV 16 and HPV 18 quantitative PCR assays with GAPDH normalization are reproducibly quantitative over a broad linear dynamic range allowing for application in epidemiologic studies for measurement of viral load.

Greening, G. E., L. Woodfield, et al. (1999). "RT-PCR and chemiluminescent ELISA for detection of enteroviruses." Journal of Virological Methods **82**(2): 157.

<http://www.sciencedirect.com/science/article/B6T96-3XT0BN2-7/2/149fa3cfe9d254a79e6a213cd2cab2cd>

Reverse transcription followed by polymerase chain reaction amplification (RT-PCR) is now used commonly to detect the presence of enteric RNA viruses in environmental samples. A sensitive, non-isotopic microtitre plate hybridisation assay was developed and applied for detection of enteroviruses in environmental samples. Following reverse transcription, viral cDNA was labelled with digoxigenin (DIG)-dUTP during the PCR amplification step. The labelled PCR products were then hybridised with enterovirus-specific biotinylated oligonucleotide probe and captured in streptavidin-coated microtitre wells. Hybridised enteroviral PCR products were detected by an anti-digoxigenin peroxidase conjugate using either a colourimetric or a chemiluminescent substrate and automated measurement. Standard curves were established for poliovirus and other enteroviruses. The chemiluminescent assay was more sensitive than the colourimetric assay for detection of poliovirus, and was specific for enteroviruses. The chemiluminescent ELISA assay was used to confirm the presence of enteroviruses in environmental water samples.

Grimm, A. C. and G. Shay Fout (2002). "Development of a molecular method to identify hepatitis E virus in water." Journal of Virological Methods **101**(1-2): 175.

<http://www.sciencedirect.com/science/article/B6T96-44PVRKC-1/2/e7b6f2e02418d20b85f1e0d2d50bb872>

Hepatitis E virus (HEV) causes an infectious form of hepatitis associated with contaminated water. By analyzing the sequence of several HEV isolates, a reverse transcription-polymerase chain reaction method was developed and optimized that should be able to identify all of the known HEV strains. When tested under laboratory conditions, this method was able to detect low levels of five diverse HEV variants. In addition, internal controls were constructed so that any PCR inhibition could be detected. Finally, virus-spiked environmental water samples were analyzed successfully with these assays.

Hammond, R. W., J. M. Crosslin, et al. (1999). "Differentiation of closely related but biologically distinct cherry isolates of *Prunus necrotic ringspot virus* by polymerase chain reaction." Journal of Virological Methods **80**(2): 203.

<http://www.sciencedirect.com/science/article/B6T96-3X29D70-C/2/18edff2a89bc88f27b8881698af3c946>

Prunus necrotic ringspot ilarvirus (PNRSV) exists as a number of biologically distinct variants which differ in host specificity, serology, and pathology. Previous nucleotide sequence alignment and phylogenetic analysis of cloned reverse transcription-polymerase chain reaction (RT-PCR) products of several biologically distinct sweet cherry isolates revealed correlations between symptom type and the nucleotide and amino acid sequences of the 3a (putative movement protein) and 3b (coat protein) open reading frames. Based upon this analysis, RT-PCR assays have been developed that can identify isolates displaying different symptoms and serotypes. The incorporation of primers in a multiplex PCR protocol permits rapid detection and discrimination among the strains. The results of PCR amplification using type-specific primers that amplify a portion of the coat protein gene demonstrate that the primer-selection procedure developed for PNRSV constitutes a reliable method of viral strain discrimination in cherry for disease control and will also be useful for examining biological diversity within the PNRSV virus group.

Hauptli, D., L. Bruckner, et al. (1997). "Use of reverse transcriptase polymerase chain reaction for detection of vaccine contamination by avian leukosis virus." Journal of Virological Methods **66**(1): 71.

<http://www.sciencedirect.com/science/article/B6T96-3RYCMYM-1C/2/18f6ba294c42adbeeda2604566560edd>

A reverse transcriptase polymerase chain reaction (RT-PCR) for avian leukosis virus (ALV) was developed for the detection of contamination of vaccines produced in embryonated eggs and cell cultures derived from chicken. ALV is highly pathogenic and induces a wide spectrum of disease in infected animals. ALV can be divided into five subgroups (A-E). The envelope glycoprotein (env gp85) is the main antigen determinant and responsible for subgroup classification. Viral RNA of all subgroups (A-E) was isolated and amplified using three sets of primers. Subsequently, restriction endonuclease analysis confirmed the product identity and discriminated between subgroups. In specific pathogen free (SPF) eggs experimentally inoculated with ALV, viral RNA was found in allantoic fluids, as well as in vaccines spiked with different subgroups of ALV. No adventitious virus was detected in commercially available preparations. This system provides a rapid and specific *in vitro* method for the detection of ALV RNA as an extraneous agent and may be applied for quality control of avian vaccines.

Hawrami, K. and J. Breuer (1999). "Development of a fluoregenic polymerase chain reaction assay

(TaqMan) for the detection and quantitation of varicella zoster virus." Journal of Virological Methods **79**(1): 33.

<http://www.sciencedirect.com/science/article/B6T96-3W7XC6H-4/2/9bbe0ae1f4316bf4978918f709a3e76a>

A TaqMan based polymerase chain reaction (PCR) assay was developed for the detection and quantitation of varicella zoster virus (VZV). This method enables simple, reproducible, sensitive and specific detection and quantification of VZV. The TaqMan assay was able to detect four copies of VZV and did not cross-react with other herpesviruses DNA. The assay has several advantages over conventional PCR. First, in the TaqMan assay there is no need for gel electrophoresis and contact with hazardous chemicals. Second, the method is rapid allowing the analysis of 92 samples within minutes after completion of PCR. Finally, the incorporation of a specific probe into the PCR reaction enhances the sensitivity and specificity of the method compared with conventional PCR. The TaqMan system could, therefore, be a useful tool for the epidemiological and diagnostic investigation of VZV.

Hays, J. P. and S. H. Myint (1998). "PCR sequencing of the spike genes of geographically and chronologically distinct human coronaviruses 229E." Journal of Virological Methods **75**(2): 179.

<http://www.sciencedirect.com/science/article/B6T96-3V5F5S6-6/2/db84d5fc2a47343679b811d468d045f2>

A reverse transcription nested PCR (RT-PCR) sequencing methodology was developed and used to generate sequence data from the spike genes of three geographically and chronologically distinct human coronaviruses 229E. These three coronaviruses were isolated originally from the USA in the 1960s (human coronavirus 229E strain ATCC VR-74), the UK in the 1990s (human coronavirus 229E LRI 281) and Ghana (human coronavirus 229E A162). Upon translation and alignment with the published spike protein sequence of human coronavirus 229E 'LP' (isolated in the UK in the 1970s), it was found that variation within the translated protein sequences was rather limited. In particular, minimal variation was observed between the translated spike protein sequence of human coronaviruses 229E LP and ATCC VR-74 (1/1012 amino acid differences), whilst most variation was observed between the translated spike protein sequence of human coronaviruses 229E LP and A162 (47/1012 amino acid changes). Further, the translated spike protein sequence of human coronavirus 229E A162 showed three clusters of amino acid changes, situated within the 5' half of the translated spike protein sequence.

Heinemeyer, T., A. Klingenhoff, et al. (1997). "A sensitive method for the detection of murine C-type retroviruses." Journal of Virological Methods **63**(1-2): 155.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-1B/2/5f203004dd348500779dd345dc7a37fb>

A RT-PCR assay was developed for group-specific detection of murine C-type retroviruses using a nested set of degenerated primers. To distinguish exogenous viruses from related, but silent endogenous viruses, a DNase I pretreatment of supernatants is applied. This is followed by a heat inactivation/denaturation step. The PCR method is ultrasensitive, which enables the detection of 100 attogram of MoMuLV proviral DNA or up to 1-10 infectious mouse C-type retroviruses in 10 [mu]l supernatant of infected cells. The high specificity of the method allows the differentiation between mouse C-type retroviruses and related retroviruses of the A, B, and D type and C-type retroviruses found in other species. It serves as a valuable tool for the screening of

animal cell cultures for contaminations with mouse retroviruses, e.g. hybridomas or recombinant cell lines producing foreign proteins.

Hofmann, M. A. (2003). "Construction of an infectious chimeric classical swine fever virus containing the 5'UTR of bovine viral diarrhea virus, and its application as a universal internal positive control in real-time RT-PCR." Journal of Virological Methods **114**(1): 77.

<http://www.sciencedirect.com/science/article/B6T96-49SWFWP-9/2/ecf6aa0b9aa5ce4e7ebac259e29b85cc>

RT-PCR is used widely as a diagnostic method to detect and differentiate pestiviruses. The construction of two chimeric classical swine fever virus (CSFV) recombinants based on a marker virus constructed previously [J. Virol. 72 (1998) 5318-5322] is described. These viruses, termed vA187CAT_5UTRBVD and vA187CAT_IRESBVD, contain the entire 5' untranslated region (5'UTR) or the internal ribosome entry site (IRES) of bovine viral diarrhea virus (BVDV), respectively. Both chimeric viruses proved to be infectious in cell culture. Hence, the 5'UTR as well as the IRES element only of BVDV can substitute for the corresponding genome region of CSFV. Next, two sets of primers and corresponding dual-labeled TaqMan(R) probes were designed; one detecting specifically a conserved but CSFV-specific area within the 5'UTR of wild-type CSFV, the other one targeting the CAT gene inserted in vA187CAT_5UTRBVD. The two primer/probe sets were combined in a closed-tube multiplex one-step RT-PCR. To monitor the entire extraction and detection process limited amounts of vA187CAT_5UTRBVD were added directly to clinical samples before RNA extraction. The multiplex RT-PCR proved to be as sensitive as the single primer/probe set method, but allowed the validation of each sample tested individually, based on the detection of the CAT marker gene. vA187CAT_5UTRBVD was also used successfully for foot-and-mouth disease virus (FMDV) TaqMan(R) RT-PCR. Therefore, it is considered a universal internal positive control for RT-PCR assays to exclude loss of RNA during extraction, or failure of amplification due to inhibitory substances present in the sample.

Hofner, M. C., W. C. Carpenter, et al. (1993). "Detection of foot-and-mouth disease virus RNA in clinical samples and cell culture isolates by amplification of the capsid coding region." Journal of Virological Methods **42**(1): 53.

<http://www.sciencedirect.com/science/article/B6T96-47YGSVX-7/2/fb924bcb48df04e1e516d9f231b84406>

Foot-and-mouth disease is one of the most economically important virus diseases of livestock. Two important requirements for the control of this disease are rapid laboratory diagnosis and epidemiological investigation. The use of the polymerase chain reaction method (PCR) to amplify specific nucleic acid regions offers the unique possibility of combining swift viral detection with the production of genetic material suitable for sequencing and other methods of molecular epidemiological analysis. The sequencing of the region of foot-and-mouth disease virus (FMDV) genome encoding the capsid proteins of the virus (~ 2260 bps), provides valuable information that adds to the molecular characterization of an isolate. This paper describes the use of the PCR for the amplification of this region of the FMDV genome from bovine clinical samples and cell culture isolates. Suitable pairs of oligonucleotide primers were selected from the published sequence of FMDV type O1, Kaufbeuren. One primer set amplified 2091 bps of the capsid coding region of all seven serotypes of FMDV. The other primer set amplified 216 bp from this region of FMDV type O1, BFS 1860, in nucleic acid extracts from several clinical samples. Nucleic acid extracts from the picornaviruses, bovine enterovirus and swine vesicular disease virus, which affect the same animals, were not amplified. Direct sequencing was carried out on the amplified fragments and showed that the PCR products were >98% homologous to published FMDV

sequences.

Houng, H.-S. H., R. Chung-Ming Chen, et al. (2001). "Development of a fluorogenic RT-PCR system for quantitative identification of dengue virus serotypes 1-4 using conserved and serotype-specific 3' noncoding sequences." Journal of Virological Methods **95**(1-2): 19.

<http://www.sciencedirect.com/science/article/B6T96-433NRB5-3/2/fe9854a050a05acce7c4cbad7e48f6a1>

A fluorogenic reverse transcriptase-polymerase chain reaction (RT-PCR) system was developed for use as a rapid diagnostic test for determining dengue viremia. The dengue virus 3'-noncoding sequence was utilized to formulate serotype-specific RT-PCR assays for quantitative identification of the four different dengue virus serotypes. A generic RT primer set containing two dengue specific anti-sense primers (DV-L1 and DV-L2) could be used to transcribe extracted viral RNA of all four dengue virus types to complementary DNA (cDNA). The resultant dengue viral cDNA could be quantitatively identified at the serotype level by the 5'-3' exonuclease assay using four serotype-specific sense primers. The fluorogenic dengue type-specific RT-PCR can detect each of the four dengue types at similar low detection limits, i.e. 20-50 plaque forming units per milliliter of serum. Two panels with four dengue reference serotypes and 134 clinical samples were used to validate detection sensitivity and specificity of the dengue serotype RT-PCR assay, using virus isolation in cell culture as the criterion standard. By analyzing sera samples from Puerto Rico that were collected from 1999 through 2000, the assay demonstrated high level detection sensitivity and specificity of 92.8 and 92.4%, respectively, for all four dengue virus serotypes.

Houng, H.-S. H., D. Hritz, et al. (2000). "Quantitative detection of dengue 2 virus using fluorogenic RT-PCR based on 3'-noncoding sequence." Journal of Virological Methods **86**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-3YS34HX-1/2/0a5f4885616059f11995aef5f257f642>

A fluorescent DNA probe (DV2.P1) specific to the conserved distal 3'-noncoding region (nucleotides 10653-10678) of dengue 2 virus and a pair of flanking primers (DV2.L1 and DV2.U2) were designed to formulate a dengue 2-specific fluorogenic polymerase chain reaction (PCR). In addition, DV2.L1 was also used as a reverse transcription (RT) primer to generate superior cDNA from dengue viral RNA. Optimal assay conditions with zero background were established to detect low levels of dengue 2 virus from clinical specimens. The range of dengue virus detection in spiked human sera was determined to be from 10 to 10⁶ infectious virions per milliliter (plaque forming units determined using Vero cell line). Dengue 2 virus isolates from different geographic regions can be detected universally and identified by the fluorogenic RT-PCR assay. Moreover, the assay is specific for dengue 2 virus and does not recognize other related flaviviruses, including dengue serotypes 1, 3 and 4, Japanese encephalitis, St. Louis encephalitis, yellow fever, and Kunjin viruses. The assay also detected efficiently immunocomplexed dengue viruses. In practice, the fluorogenic RT-PCR assay detected readily viremia in sera collected from individuals ill with dengue fever. The rise and fall of dengue 2 virus concentrations in rhesus monkeys, reflecting viral proliferation and clearance, was also clearly illustrated by the assay.

Houng, H.-S. H., D. Norwood, et al. (2004). "Development and evaluation of an efficient 3'-noncoding region based SARS coronavirus (SARS-CoV) RT-PCR assay for detection of SARS-CoV

infections." Journal of Virological Methods **120**(1): 33.

<http://www.sciencedirect.com/science/article/B6T96-4CJVJR6-1/2/905fb4fa8e6218acd28373a8e9e90b64>

The severe acute respiratory syndrome (SARS) epidemic originating from China in 2002 was caused by a previously uncharacterized coronavirus that could be identified by specific RT-PCR amplification. Efforts to control future SARS outbreaks depend on the accurate and early identification of SARS-CoV infected patients. A real-time fluorogenic RT-PCR assay based on the 3'-noncoding region (3'-NCR) of SARS-CoV genome was developed as a quantitative SARS diagnostic tool. The ideal amplification efficiency of a sensitive SARS-CoV RT-PCR assay should yield an E value (PCR product concentration increase per amplification cycle) equal to 2.0. It was demonstrated that the 3'-NCR SARS-CoV based RT-PCR reactions could be formulated to reach excellent E values of 1.81, or 91% amplification efficacy. The SARS-CoV cDNA preparations derived from viral RNA extract and the cloned recombinant plasmid both exhibit the identical amplification characteristics, i.e. amplification efficacy using the same PCR formulation developed in this study. The viral genomic copy (or genomic equivalences, GE) per infectious unit (GE/pfu) of SARS-CoV used in this study was also established to be approximate 1200-1600:1. The assay's detection sensitivity could reach 0.005 pfu or 6-8 GE per assay. It was preliminarily demonstrated that the assay could efficiently detect SARS-CoV from clinical specimens of SARS probable and suspected patients identified in Taiwan. The 3'-NCR based SARS-CoV assay demonstrated 100% diagnostic specificity testing samples of patients with acute respiratory disease from a non-SARS epidemic region.

Hoyland, J. A., J. A. Dixon, et al. (2003). "A comparison of in situ hybridisation, reverse transcriptase-polymerase chain reaction (RT-PCR) and in situ-RT-PCR for the detection of canine distemper virus RNA in Paget's disease." Journal of Virological Methods **109**(2): 253.

<http://www.sciencedirect.com/science/article/B6T96-488G8YB-2/2/8749aa4932edd03dc0163ff7236499ce>

Previous evidence implicating Paramyxoviruses in the aetiopathology of Paget's disease of bone has proved controversial. Whilst several groups have demonstrated Paramyxoviruses using techniques such as in situ hybridisation (ISH), reverse transcriptase-polymerase chain reaction (RT-PCR), and in situ-RT-PCR (IS-RT-PCR), others have found no evidence of viruses using only RT-PCR. To investigate this latter finding, we have now compared detection of canine distemper virus by ISH, RT-PCR (three different methods) and IS-RT-PCR, in 10 patients with Paget's disease, and samples of non-diseased bone from four patients. Canine distemper virus was detectable in six of the samples by ISH, but only in five of the samples by RT-PCR, using one of the methods. Neither of the other RT-PCR methods detected canine distemper virus. IS-RT-PCR demonstrated canine distemper virus in all 10 samples. There was no evidence of virus in the control samples. We have shown that the ability to detect canine distemper virus in bone is dependent on the technique used. IS-RT-PCR clearly showed that canine distemper virus was present in 100% of Pagetic samples, whereas canine distemper virus was only found in 60% by ISH and in 50% using one particular RT-PCR method. These results provide conclusive evidence that canine distemper virus is present within Pagetic bone, and provide a possible explanation for the failure of some groups to detect Paramyxovirus sequences. These findings also have wider implications for other studies investigating viral expression.

Ijzerman, M. M., D. R. Dahling, et al. (1997). "A method to remove environmental inhibitors prior to the detection of waterborne enteric viruses by reverse transcription-polymerase chain reaction." Journal of Virological Methods **63**(1-2): 145.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-19/2/d082502d074d3579f7dfa4541d72c8a4>

A method was developed to remove environmental inhibitors from sample concentrates prior to detection of human enteric viruses using the reverse transcription-polymerase chain reaction (RT-PCR). Environmental inhibitors, concentrated along with viruses during water sample processing, are removed by the method through a series of steps that includes dialysis, solvent extraction, ultrafiltration and glass purification. The method was tested by spiking sodium phosphate with poliovirus type 1 with or without humic or fulvic acids and then measuring virus recovery by plaque assay and RT-PCR. Results of the study indicated that (i) 90% of the spiked virus could be recovered from samples at the end of the ultrafiltration step, (ii) virus was detected in the final eluate of samples containing as much as 0.5 mg of humic acid or 5.0 mg of fulvic acid, and (iii) as little as 0.06 plaque forming units (PFU) was detectable per RT-PCR reaction. These results indicate that the described purification method along with RT-PCR is a feasible approach for detecting waterborne human enteric viruses in the presence of interfering substances.

Inoshima, Y., A. Morooka, et al. (2000). "Detection and diagnosis of parapoxvirus by the polymerase chain reaction." Journal of Virological Methods **84**(2): 201.

<http://www.sciencedirect.com/science/article/B6T96-3YDG9HS-C/2/f99b5e663728bcc0f6b91033a27867b>

The genus Parapoxvirus includes four members, bovine papular stomatitis virus (BPSV), pseudocowpox virus (PCPV), orf virus (ORFV) and parapoxvirus of red deer in New Zealand (PVNZ). A set of primers for polymerase chain reaction (PCR) was designed to detect viral DNA from cells infected with each of the four parapoxviruses. The set of primers resulted in the amplification of appropriately sized products from cells infected with BPSV, PCPV, ORFV and PVNZ, respectively. The PCR method was applied for the detection of seven field isolates of parapoxvirus from cattle, sheep and free-ranging wild Japanese serows. The expected size of DNA was amplified from cells infected with each of the seven isolates. No specific PCR products were detected from vaccinia virus-, fowlpox virus- and mock-infected cells. Moreover, by a semi-nested PCR with an inner primer and Southern blot analysis, viral DNA was detected from lesions of clinically affected cattle, sheep and Japanese serows. These results suggested that the PCR method used in this study was specific for the detection of parapoxviruses and thus useful for diagnosis of parapoxvirus infections, especially in discrimination from diseases with similar clinical symptoms.

Ito, T., H. Ieki, et al. (2002). "Simultaneous detection of six citrus viroids and Apple stem grooving virus from citrus plants by multiplex reverse transcription polymerase chain reaction." Journal of Virological Methods **106**(2): 235.

<http://www.sciencedirect.com/science/article/B6T96-46WSX8S-1/2/58a09d09703fa70372a5ba9d5e86230c>

We developed a multiplex reverse transcription polymerase chain reaction (RT-PCR) to detect six citrus viroids: Citrus exocortis viroid (CEVd), Citrus bent leaf viroid (CBLVd), Hop stunt viroid (HSVd), Citrus viroid III (CVd-III), Citrus viroid IV (CVd-IV) and Citrus viroid OS (Cvd-OS) and Apple stem grooving virus (ASGV, synonym: Citrus tatter leaf virus (CTLV)) from citrus plants. The multiplex RT-PCR was also designed to distinguish Cvd-I-LSS (a distinct variant of CBLVd) from CBLVd. By the multiplex RT-PCR, one to eight fragments specific to the pathogens were simultaneously amplified from one sample and identified by their specific molecular sizes in 6%

polyacrylamide gel electrophoresis. The results of the multiplex RT-PCR were consistent with those of other diagnoses, such as uniplex RT-PCR, to detect each of the pathogens. The multiplex RT-PCR provides a simple and rapid method for detecting various viroids and ASGV in citrus plants, which will help diagnose many citrus plants at a time.

Jacquot, E., M. Tribodet, et al. (2005). "A single nucleotide polymorphism-based technique for specific characterization of YO and YN isolates of Potato virus Y (PVY)." Journal of Virological Methods **125**(1): 83.

<http://www.sciencedirect.com/science/article/B6T96-4FFH1XG-1/2/9cbcec844d2200fffb8c12c19f0afd84>

One of the most important properties used to classify Potato virus Y (PVY) isolates is their ability to induce (PVYN) or not (PVYO) veinal necrosis symptoms on the indicator host plant *Nicotiana tabacum* cv. Xanthi. As an alternative to biological assays, several serological and molecular detection tools have been developed for PVY detection and characterization and these have evolved as our knowledge of PVY has improved. However, the assays that have been previously published are all based on the use of neutral markers (antigenic determinants, sequence data, recombination sites or restriction enzyme cleavage sites), which are unlinked to the biological property being characterized (e.g. veinal necrosis). Using the recently identified molecular determinants of the tobacco leaf necrosis symptom induced by PVYN isolates, a one-step fluorescent [TaqMan[®]] RT-PCR assay, based on a single nucleotide polymorphism (SNP) linked to the necrosis property of PVY isolates, has been designed. This assay reliably detects and distinguishes PVYN and PVYO isolates. The method is simple (leaf soak extraction process, gel-free, no post-PCR manipulations), rapid (96 tests in less than 3 h from plants sampling to diagnostic results), sensitive (threshold in a range of 10⁴-10⁵ PVY copies), reliable (correctly assigns 42 PVY isolates in their respective group) and allows co-detection of mixed samples containing close to equivalent PVYN and PVYO quantities. All these characteristics suggest that the newly developed SNP assay could be used to reliably classify PVY isolates, as a substitute for biological assays performed on *N. tabacum* cv. Xanthi.

Jordens, J. Z., S. Lanham, et al. (2000). "Amplification with molecular beacon primers and reverse line blotting for the detection and typing of human papillomaviruses." Journal of Virological Methods **89**(1-2): 29.

<http://www.sciencedirect.com/science/article/B6T96-429RNYH-4/2/4deb02669f9ef56632dd6a8d9523d8e1>

A novel method for the detection and typing of human papillomavirus (HPV) was developed using molecular beacon primers. The method is based on the use of HPV-specific primers containing a hairpin loop structure in which fluorescent donor and quencher groups are held in close proximity such that fluorescence is quenched. Amplification of the target sequence results in the opening of the loop and the resulting fluorescence can be detected on a sequence detector system (SDS 7700 (Applied Biosystems), as used for TaqMan[®] assays. Fluorescent amplicons were identified on the SDS 7700 and then typed by a single hybridisation with specific probes immobilised in lines on a nylon membrane and detected on a fluorescent scanner. This novel beacon primer method compared well with conventional PCR for cervical scrape specimens. The combination of the beacon primer method and reverse line blotting should enable large-scale population studies of HPV infection.

Kanematsu, S., T. Hibi, et al. (1991). "Comparison of nonradioactive cDNA probes for detection of potato spindle tuber viroid by dot-blot hybridization assay." Journal of Virological Methods **35**(2): 189.

<http://www.sciencedirect.com/science/article/B6T96-476RM29-11/2/2ec189aaa939c16854589fee60f6800d>

Six nonradioactive cDNA probes were compared for their sensitivities for detecting potato spindle tuber viroid (PSTVd) by dot-blot hybridization assay. Three biotinylated PSTVd cDNA probes, labeled by photoactivation with photobiotin, by nick translation or by random priming with biotinylated deoxyribonucleotides, were all capable of detecting 20 pg of purified PSTVd by a colorimetric assay and 2-20 pg by a chemiluminescent assay. Digoxigeninlabeled probe was able to detect 200 pg of purified PSTVd. Two biotinylated probes prepared with polymerase chain reaction (PCR) incorporating biotinylated dUTP or dATP were the most sensitive: 0.2-2 pg of PSTVd was detectable by both assays. All six probes could detect PSTVd also in extracts of infected tomato leaves at a dilution of up to 1/250-1/1250. These nonradioactive probes are equal to radioactive probes in their sensitivity, and the biotinylated probes produced with PCR amplification are particularly suitable for practical diagnosis, as they are sensitive and rapidly prepared in large quantities.

Kato, H., E. Orito, et al. (2001). "Determination of hepatitis B virus genotype G by polymerase chain reaction with hemi-nested primers." Journal of Virological Methods **98**(2): 153.

<http://www.sciencedirect.com/science/article/B6T96-441N4XX-7/2/832c9c9efcf60538867ea86e644c8315>

Hepatitis B virus (HBV) has been classified into six genotypes designated A-F by sequence divergence in the entire genome exceeding 8%. Very recently, the seventh genotype was reported and named genotype G. HBV genotype G is distinct from genomes of the other six genotypes in that it possesses an insertion of 36 nucleotides in the core gene, and has been found so far in France and the United States. A method for determining HBV genotype G was developed by polymerase chain reaction (PCR) with primers deduced from the 36-nucleotide (nt) insertion in five isolates of HBV genotype G the sequences of which have been deposited in DNA databases. The validity of this method, for specifically detecting HBV genotype G, was verified on a panel consisting of 142 HBV isolates of six major genotypes and four of genotype G. A total of 540 sera containing HBV in Japan covering symptom free carriers and patients with a spectrum of chronic liver disease were tested by this method, but not a single HBV genotype G sample was found. A possible method for serological determination of hepatitis B surface antigen of genotype G is suggested, without amplification or sequencing nucleotides, which would expand epidemiological and clinical researches on HBV genotype G.

Kato, H., E. Orito, et al. (2003). "Frequent coinfection with hepatitis B virus strains of distinct genotypes detected by hybridization with type-specific probes immobilized on a solid-phase support." Journal of Virological Methods **110**(1): 29.

<http://www.sciencedirect.com/science/article/B6T96-48B0RKS-1/2/ea1b60574eee9bfdd94e8a79cb120c39>

A genotype-specific probes assay (GSPA) was developed for distinguishing the seven genotypes (A-G) of hepatitis B virus (HBV). Nucleotide (nt) sequences corresponding to preS1 region were amplified by PCR with a primer labeled with biotin, and delivered to eight wells on which complementary sequences specific to one or other genotype had been immobilized. Thereafter,

hybridization of HBV DNA sequences amplified from the test serum was detected by colorimetry. When 256 sera from HBV carriers in Bangladesh, Cameroon, Japan, South Africa, USA and Uzbekistan were subjected to GSPA, genotypes were concordant with those of ELISA with monoclonal antibodies to epitopes on preS2-region products in 242 (94.6%) of them; 8 sera (3.1%) were not genotypeable by either method. Cloning analysis confirmed the presence of two distinct HBV genotypes in the seven selected sera with coinfection. There were 7 (2.7%) sera with discordant genotyping results between GSPA and ELISA. When HBV DNA clones propagated from these sera were sequenced and analyzed phylogenetically, the genotypes determined by GSPA were verified. Coinfection with HBV strains of two distinct genotypes was identified by GSPA in 28 (10.9%) sera, while it was suggested by ELISA in only 2 (0.8%) sera. The GSPA method would be particularly useful for detecting the coinfection with distinct HBV genotypes of any clinical relevance, which seems to be more frequent than reported previously.

Kato, S., Y. Hiraishi, et al. (1998). "A plaque hybridization assay for quantifying and cloning infectious human immunodeficiency virus type 1 virions." *Journal of Virological Methods* **72**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-3SXDERR-1/2/f51fff8e04c825e5117efdc82ec50011>

A biological method was developed for quantifying and cloning of infectious virions of human immunodeficiency virus type 1 (HIV-1). Virus preparations were mixed with permissive cells for binding, and the cells were cast in an agarose gel. After incubation for 9 days viral particles released from infected cells propagating from each initially infected cell were transferred on nylon membrane and subjected to hybridization using a radioactive HIV-1 DNA probe. Infectious centers of HIV-1 were detected as hybridization spots on autoradiographs regardless of cytopathic effects or syncytium formation. Three different CD4⁺ cell lines (MT-4, MOLT-4 and U937) and peripheral blood mononuclear cells from healthy donors were used as recipient cells. Infectious virions were recovered from a portion of agarose gel corresponding to each hybridization spot. This assay is suitable for quantifying infectious HIV-1 virions with different cell tropisms and for investigating the relationship between the phenotype and genotype of HIV-1 at a clonal level.

Kay, P., K. Meehan, et al. (2002). "The use of nested polymerase chain reaction and restriction fragment length polymorphism for the detection and typing of mucosal human papillomaviruses in samples containing low copy numbers of viral DNA." *Journal of Virological Methods* **105**(1): 159.

<http://www.sciencedirect.com/science/article/B6T96-460DN3D-2/2/8d3a222d9b4ec8b3c8d97c518fd09b80>

Mucosal human papillomaviruses (HPVs) that infect the genital area have also been shown to infect the oral cavity. In this study a restriction fragment length polymorphism (RFLP) method was developed on a nested polymerase chain reaction (PCR) product to identify ten high risk HPV types 16, 18, 31, 33, 35, 45, 51, 52, 58 and 59 as well as the low risk HPV 11. HPV DNA was detected in 23/31 (74%) of buccal specimens using a sensitive nested PCR employing degenerate consensus primers (Williamson and Rybicki, 1991). Consensus PCR using the PGM09/11 primers was able to detect HPV in only 29% of the specimens that had tested positive using the nested HPV PCR primers. HPV 11 type specific primers detected HPV 11 DNA in only 66% of the specimens showing HPV 11 DNA by means of nested PCR and RFLP. A Genbank search revealed that the PCR primers could detect a wide range of mucosal HPV types including types HPV 70, 72 and 73 which have all been isolated from immunocompromised patients. Of the 23 buccal specimens that were positive for HPV DNA, 13 were single infections, five were dual infections and three were triple infections. The HPV types identified by RFLP were:

HPV 11 (18/23), HPV 18 (8/23), HPV 16 (3/23), and HPV 33 (1/23). HPV 13 (2/23) was identified by direct sequencing of the inner amplicon of the PCR product.

Kaye, S., C. Loveday, et al. (1991). "Storage and preservation of whole blood samples for use in detection of human immunodeficiency virus type-1 by the polymerase chain reaction." Journal of Virological Methods **35**(2): 217.

<http://www.sciencedirect.com/science/article/B6T96-476RM29-14/2/ca3b2230e241dea9b5bde9cab36a6b2b>

Methods used in the diagnosis of human immunodeficiency virus type-1 (HIV-1) infection by the polymerase chain reaction (PCR) usually require the separation of lymphocytes from a whole-blood sample within 24 hours of patient sampling. A method is described in which blood samples are mixed with a cryopreservative ('Glycigel'), stored frozen, and DNA suitable for use in an HIV PCR recovered. Samples can be stored at --20[deg]C for up to 3 months and still give positive results with all samples from infected patients; storage at --80[deg]C for at least 3 months shows no loss of titre. The method shows no loss of sensitivity compared to previously described sample preparation methods. Deglycerolised Glycigel supernatants were found to be suitable for conventional anti-HIV-1 serological studies and loss of sensitivity only represented the dilution effect due to sample preparation. Application of the method as a means of storing samples frozen at the point of sampling and transporting them to a central laboratory for processing is demonstrated using samples taken from HIV-1-infected mothers and their babies.

Khare, M., M. Sharland, et al. (2004). "Use of serial maternal urine cytomegalovirus PCR to detect primary CMV infection in seronegative pregnant women." Journal of Virological Methods **119**(1): 31.

<http://www.sciencedirect.com/science/article/B6T96-4C4X49B-1/2/481324f9b43b650ff596845f3a38616a>

The aim of the study was to determine if serial maternal urine polymerase chain reaction (PCR) tests can detect primary CMV infection during pregnancy. This was a prospective study conducted from 1 January 1999 to 31 December 1999 in an antenatal clinic setting of a teaching hospital. The study group included women who were CMV IgG negative and aged At first attendance, 1549 (42%) women were CMV IgG negative. Of the 696 eligible women, 609 (88%) participated in the urine PCR study. PCR was performed on 2263 urine samples (median of 4/pregnancy). Primary CMV infection was identified in one woman by urine PCR at 36 weeks (baby CMV negative). Cord blood samples were available from 152/609 infants (25%). Seroconversion was noted in only one woman. Replies to the questionnaire were received from 264/609 women (43%): 214 (81%) had little or no anxiety, and 220 (83%) felt reassured by their study participation. Serial urine PCR is a feasible method of detecting primary maternal CMV infection during pregnancy which has potential for evaluation in further studies.

Kim, Y., S. M. Gharaibeh, et al. (2002). "Comparison and verification of quantitative competitive reverse transcription polymerase chain reaction (QC-RT-PCR) and real time RT-PCR for avian leukosis virus subgroup J." Journal of Virological Methods **102**(1-2): 1.

<http://www.sciencedirect.com/science/article/B6T96-456T3KB-1/2/6e9c9b6a0052a9435c1a9243adcf070c>

Avian leukosis virus subgroup J (ALV-J) infections cause significant economic losses because of increased mortality, tumor production, decreased production, and cost for eradication. Current quantification methods for ALV-J expressed by TCID₅₀ are difficult to determine because of the lack of cytopathic effect in cell cultures and non-specificity of currently available antigen-capture ELISA tests. In this study, a one-tube fluorescent probe based real time RT-PCR method was developed for quantification of ALV-J and compared with available quantification methods. Cell lysates with different TCID₅₀s determined by cell culture and antigen capture ELISA (ag-ELISA) were used for one-tube real time RT-PCR using fluorogenic probe and quantitative competitive RT-PCR (QC-RT-PCR). The results of QC-RT-PCR and real time RT-PCR were highly correlated to the TCID₅₀s determined by conventional culture methods. They were also very specific, sensitive, easy to perform, reproducible, and rapid compared with conventional methods. These RT-PCR based quantification methods of ALV-J viral RNA will be useful for virological and pathogenesis studies.

Klein, S. A., S. Karsten, et al. (2003). "Comparison of TaqMan(TM) real-time PCR and p24 Elisa for quantification of in vitro HIV-1 replication." *Journal of Virological Methods* **107**(2): 169.

<http://www.sciencedirect.com/science/article/B6T96-47DTDTF-9/2/b94c148adc8c912c06fe39684545b9df>

In this study, TaqMan(TM) PCR was used to assess viral replication of HIV-1 infected cells in vitro. This PCR technique was compared with p24 ELISA as a standard method to monitor HIV-1 replication in cell culture. Hut78 T-lymphoblastoid cells were infected with different titres of HIV-1IIIB (MOI 0.05-0.0005). The course of HIV-1 replication was monitored by determination of p24 concentrations by ELISA in cell culture supernatants and by quantitation of HIV-1 gag RNA by TaqMan(TM) RT-PCR. Additionally, the number of HIV-1 proviral copies was assessed by TaqMan(TM) PCR. Monitoring of HIV-1 replication by p24 ELISA and TaqMan(TM) RT-PCR revealed comparable kinetics of infection. Both methods provided similar data on the exponential increase and on plateauing of HIV-1 replication. Furthermore, both methods were equally sensitive. However, a 7 log linearity of TaqMan(TM) HIV-1 gag PCR was demonstrated without dilution of the specimen, in contrast to p24 ELISA, where because of its narrow range of detectable p24 concentrations, sample dilution was necessary. Although determination of the number of proviral copies by TaqMan(TM) PCR does not measure HIV-1 replication, the kinetics of proviral copy number following in vitro inoculation of cells with HIV-1 was nearly the same as the kinetics of HIV-1 RNA copy numbers. In conclusion, TaqMan(TM) real-time RT-PCR was demonstrated as a reliable and sensitive tool to quantify and monitor HIV-1 replication in cell culture. It is suggested, therefore, that this technique be an alternative method to monitor HIV-1 replication in vitro.

Koch, N., N. Yahi, et al. (1999). "Genetic polymorphism near HIV-1 reverse transcriptase resistance-associated codons is a major obstacle for the line probe assay as an alternative method to sequence analysis." *Journal of Virological Methods* **80**(1): 25.

<http://www.sciencedirect.com/science/article/B6T96-3WM5CT3-4/2/92f54634868a5eb138d5389ecd3ae41d>

The performance of the line probe assay (LIPA) for the detection of mutations conferring resistance to nucleoside inhibitors of HIV-1 reverse transcriptase was evaluated in comparison with sequence analysis. The tests were undertaken on plasma samples from 63 patients (61 receiving combination therapy and 2 without treatment at the time of inclusion). In 27 cases (43%) which included codons 41, 69, 70, 74, 184 and 215, the sequence of the RT gene was distinct from the hybridization probes used in LIPA. Correspondingly, LIPA gave uninterpretable results in

15, 30 and 41% of cases for codons 184, 215 and 41, respectively. Overall, the concordance between LIPA and sequence analysis varied from 52% (codons 41 and 215) to 85% (codon 70). These data show that the polymorphism of the nucleotide sequence near resistance-associated codons is a major shortcoming of LIPA.

Koch, W. C. (1995). "A synthetic parvovirus B19 capsid protein can replace viral antigen in antibody-capture enzyme immunoassays." Journal of Virological Methods **55**(1): 67.

<http://www.sciencedirect.com/science/article/B6T96-3YYTF0W-16/2/706a803b814c4e78c220b3b597852ab7>

To establish a renewable source of parvovirus B19 antigens for diagnostic tests, gene sequences for the viral capsid proteins, VP1 and VP2, were cloned into baculovirus expression vectors and the recombinant viruses used to infect Sf9 insect cells. Cell lysates examined by immunoblotting demonstrated reactive proteins corresponding to the expected sizes of native VP1 (83 kDa) and VP2 (58 kDa). The VP2 protein was produced efficiently in quantity and self-assembled into empty capsids as shown by density equilibration in a CsCl step gradient. The VP2 protein was purified and used as an antigen in antibody-capture enzyme immunoassays for the detection of B19 IgG and IgM antibodies. Compared to a standard antibody-capture EIA based on whole viral antigen, the VP2-EIA gave a sensitivity of 100% and specificity of 97% in detection of B19 IgM in 138 patients suspected of B19 infection. No IgM-positive specimens were missed. IgG detection yielded a sensitivity of 100% and specificity of 96% in the same population. Recombinant VP2 capsid proteins expressed in baculovirus-infected insect cells can substitute for serum-derived B19 virus in standard antibody-capture EIA for the detection of B19 IgG and IgM with comparable results.

Koskiniemi, M., L. Mannonen, et al. (1997). "Luminometric microplate hybridization for detection of varicella-zoster virus PCR product from cerebrospinal fluid." Journal of Virological Methods **63**(1-2): 71.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-11/2/27d2c8daff233d32eae2eab70a91d62>

We modified and optimized a new microplate hybridization assay to detect the varicella-zoster virus (VZV) PCR product, and studied cerebrospinal fluid (CSF) samples of 287 patients with meningitis, encephalitis or other neurological diseases or symptoms. Specific antibodies to VZV and reference antigens were determined by enzyme immunoassay from serum and CSF, they were then compared with clinical findings and with the results obtained by VZV-PCR using different detection methods for VZV-specific amplified DNA. VZV DNA was found in the CSF of 25 patients using the microplate hybridization assay and chemiluminescence detection for amplified DNA. All 25 CSF samples were also positive in Southern blotting. Among the patients, 10 had chickenpox, 4 had shingles, and 11 had no rash at all. The detection rate of VZV-specific DNA by microplate hybridization was 30% higher than that obtained by conventional agarose gel electrophoresis. In most patients the diagnosis was confirmed by demonstrating specific intrathecal antibody production to VZV but not to other viruses. These results indicate the presence of VZV in the central nervous system (CNS) in many patients with chickenpox or shingles, and even in patients without a rash. The microplate hybridization assay based on chemiluminescence detection improves considerably the detection rate of the VZV-PCR product compared to agarose gel electrophoresis and will add to the list of recognized VZV infections in the CNS. It is especially useful in cases where there is no cutaneous manifestation.

Kumar, R., N. Vandegraaff, et al. (2002). "Evaluation of PCR-based methods for the quantitation of integrated HIV-1 DNA." Journal of Virological Methods **105**(2): 233.

<http://www.sciencedirect.com/science/article/B6T96-4619PYS-2/2/50ec536b8842a95e00e4b09d1a2a1017>

Integration of HIV-1 DNA is essential both for productive viral replication and for viral persistence in patients. Methods to measure specifically proviral HIV DNA are required for investigating the mechanisms of HIV integration, for screening novel integrase inhibitors in cell culture and for monitoring levels of persistent integrated viral DNA in patients. In this report, the linker primer polymerase chain reaction (LP-PCR) and Alu-PCR methods for the quantitation of integrated HIV-1 DNA have been modified and evaluated. Each of the two modified assays allowed the quantitative detection of 4 copies of integrated HIV DNA in presence of 2×10^5 cell-equivalents of human chromosomal DNA. The results show that proper DNA isolation procedures and the inclusion of appropriate controls in these assays are important for the accurate quantitation of integrated HIV DNA. With further improvements, it should be possible to use these methods as diagnostic tools to monitor closely the efficacy of antiretroviral therapy.

Kuno, G. (1998). "Universal diagnostic RT-PCR protocol for arboviruses." Journal of Virological Methods **72**(1): 27.

<http://www.sciencedirect.com/science/article/B6T96-3SXDERR-4/2/86a293289d7bd9826c94221c46474c83>

A selected number of PCR protocols were evaluated to determine if they could serve as a universal protocol for detecting and identifying all arboviruses. In this study, four parameters that affect the efficacy of RT-PCR (RNA extraction method, choice of reverse transcriptase, choice of DNA polymerase and thermocycling program) were evaluated in combination. The most optimal combination of those parameters employed use of silica gel membrane spin column, RAV-2 reverse transcriptase, Tth DNA polymerase, and a simple modification of a published thermocycling program. By this modified protocol, viral RNA could be amplified satisfactorily with more than 50 pairs of primers designed for diagnosis of arboviruses representing five families. The sensitivity and specificity obtained by this universal protocol were comparable to those obtained by the original protocol for each primer pair tested; and for some primers, improved sensitivity was observed. It was also found that a simple modification of a suggested protocol of a commercial RT-PCR kit could produce nearly identical results and serve as another universal protocol. With the use of a universal diagnostic reverse transcriptase-polymerase chain reaction (RT-PCR) protocol, simultaneous screening of clinical or biological specimens against a large number of RNA viruses belonging to many families can be performed more efficiently for etiologic determination in the situations complicated by the difficulty of differential diagnosis. Furthermore, such a universal protocol facilitates reducing the cost of PCR-based diagnostic operation and standardizing the qualities of PCR-based diagnosis within an institution or among collaborating institutions. A logical strategy is to conduct diagnosis in two stages by using broadly group-reactive primers in the first stage to narrow the range of possible etiologic agents and using virus-specific primers in the second stage for identification. Before such a strategy is employed, however, more group-reactive primers for a large number of arboviruses, for which no such primers currently exist, must be made available. Furthermore, the best pair or pairs of primers need to be selected for each virus for the second stage of the strategy.

Laassri, M., V. Chizhikov, et al. (2003). "Detection and discrimination of orthopoxviruses using microarrays of immobilized oligonucleotides." Journal of Virological Methods **112**(1-2): 67.

<http://www.sciencedirect.com/science/article/B6T96-496G002-1/2/007ea0d0150c0536163d989adc6b4e14>

Variola virus (VARV), causing smallpox, is a potential biological weapon. Methods to detect VARV rapidly and to differentiate it from other viruses causing similar clinical syndromes are needed urgently. We have developed a new microarray-based method that detects simultaneously and discriminates four orthopoxvirus (OPV) species pathogenic for humans (variola, monkeypox, cowpox, and vaccinia viruses) and distinguishes them from chickenpox virus (varicella-zoster virus or VZV). The OPV gene C23L/B29R, encoding the CC-chemokine binding protein, was sequenced for 41 strains of seven species of orthopox viruses obtained from different geographical regions. Those C23L/B29R sequences and the ORF 62 sequences from 13 strains of VZV (selected from GenBank) were used to design oligonucleotide probes that were immobilized on an aldehyde-coated glass surface (a total of 57 probes). The microchip contained several unique 13-21 bases long oligonucleotide probes specific to each virus species to ensure redundancy and robustness of the assay. A region approximately 1100 bases long was amplified from samples of viral DNA and fluorescently labeled with Cy5-modified dNTPs, and single-stranded DNA was prepared by strand separation. Hybridization was carried out under plastic coverslips, resulting in a fluorescent pattern that was quantified using a confocal laser scanner. 49 known and blinded samples of OPV DNA, representing different OPV species, and two VZV strains were tested. The oligonucleotide microarray hybridization technique identified reliably and correctly all samples. This new procedure takes only 3 h, and it can be used for parallel testing of multiple samples.

Leary, T. P., J. C. Erker, et al. (1999). "Optimized PCR assay for the detection of TT virus." Journal of Virological Methods **82**(2): 109.

<http://www.sciencedirect.com/science/article/B6T96-3XT0BN2-1/2/218fc9f1a094d1bcbb614bf4c889a922>

A polymerase chain reaction (PCR)-based procedure for the detection of TT virus DNA is described. In this method, total nucleic acid extracted from a small volume of serum or plasma is utilized as a template in PCR employing TT virus specific primers designed to highly conserved regions of the virus genome. Additional sensitivity is obtained by carrying out a second round of amplification. Reactions are analyzed by agarose gel electrophoresis, and samples having an ethidium bromide stainable fragment of the appropriate size in the first and/or second amplification are designated as positive. This protocol allows for the rapid and sensitive detection of TT virus in human plasma or serum.

Leary, T. P., J. C. Erker, et al. (2002). "Detection of reovirus by reverse transcription-polymerase chain reaction using primers corresponding to conserved regions of the viral L1 genome segment." Journal of Virological Methods **104**(2): 161.

<http://www.sciencedirect.com/science/article/B6T96-45NPJB7-2/2/6c1eba241a205166b4ff2f88b41d233b>

A rapid, reverse transcription-polymerase chain reaction (RT-PCR) procedure for the detection of reovirus RNA in cell culture is described. Total nucleic acids are extracted from a small volume of cell culture supernatant and reverse transcribed using random hexamers. An aliquot of cDNA is

then utilized in nested PCR. The PCR primers correspond to sequences conserved between prototype reovirus strains type 1 Lang, type 2 Jones, and type 3 Dearing, as well as those of several reovirus field-isolate strains. Reactions are analyzed by agarose gel electrophoresis, and samples showing a band of the appropriate size in the first and second amplification, or in the second amplification alone, are designated as positive. This protocol allows for the rapid and sensitive detection of reovirus in cell culture. The RT-PCR methods described below can easily be adapted to the amplification of reovirus from other media, including preserved tissues, clinical specimens, and water.

Lednicky, J. A. and J. S. Butel (1997). "A coupled PCR and restriction digest method for the detection and analysis of the SV40 regulatory region in infected-cell lysates and clinical samples." Journal of Virological Methods **64**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-1T/2/5e1cc0d23751272b6e2e2c9f33c73422>

The polymerase chain reaction (PCR) is an increasingly popular analytical tool for the detection of virus sequences in laboratory preparations as well as in human clinical samples. In studies involving papovaviruses SV40, BK virus (BKV), and JC virus (JCV), one of the primary targets for analysis is the viral regulatory region, as that section of the papovavirus genome is distinct. A primary concern with PCR-based studies is whether amplified DNA sequences may be derived from laboratory contaminants. Recognizing that common sources of PCR contamination are the positive control templates, we devised a facile method to distinguish between real and false-positive PCR-amplified SV40 regulatory region DNAs. SV40 constructs that had been engineered to contain different combinations of 72-basepair (bp) enhancer elements and 21-bp repeats, as well as two introduced unique restriction enzyme sites, were used as positive control templates for PCR amplification. Cleavage of PCR-amplified DNA identifies products from the engineered control plasmids. The procedure is rapid, simple and cost-effective. We also report that primer sets predicted to be specific for the SV40 regulatory region can be used to amplify BKV and JCV regulatory region sequences under conditions of reduced stringency.

Lee, K., Y.-G. Kim, et al. (2003). "Shuttle PCR-based cloning of the infectious adeno-associated virus type 5 genome." Journal of Virological Methods **111**(2): 75.

<http://www.sciencedirect.com/science/article/B6T96-4909KV7-1/2/d0e897df2d49beb9c542361f3efdddae>

Adeno-associated virus type 5 (AAV5), which is distinct from the other serotypes of AAV, has attracted considerable interest as a premier gene delivery vector. As do the other serotypes, AAV5 contains its 4.7 kb-sized, single-stranded genome flanked with inverted terminal repeats (ITRs) in a hairpin conformation, which serves frequently as pause and arrest sites for DNA polymerases during PCR. To amplify the full-length of the AAV5 genome in single step, we established a shuttled, long and accurate PCR (LA-PCR) procedure in the present study. Furthermore, helper oligonucleotides, which hybridize with the palindromic sequence elements in ITR, were designed and employed in PCR to prevent the formation of hairpin structures by highly GC-rich ITRs. Consequently, a 4.7 kb-sized PCR product was amplified successfully, and cloned into a pBluescript(R) II KS(+) plasmid. Six plasmids, harboring the full-length AAV5 genome, rescued wild type AAV5 viruses on transfection to HeLa and HEK 293 cells, which were co-infected with helper adenoviruses. Western and Southern blot analyses supported further the fact that the pAAV5 plasmids harbored the full-length AAV5 genome. The PCR method described in this study is applicable for the cloning of genomes containing variable palindromic structures, in addition to AAV genomes of other serotypes.

Legeay, O., S. Bounaix, et al. (1997). "Development of a RT-PCR test coupled with a microplate colorimetric assay for the detection of a swine Arterivirus (PRRSV) in boar semen." Journal of Virological Methods **68**(1): 65.

<http://www.sciencedirect.com/science/article/B6T96-3RYCMYM-X/2/6615b6b3f64d2a785fcc20c09bffd5>

Transmission of porcine reproductive and respiratory syndrome virus (PRRSV) through boar semen has been demonstrated, stressing the need for a reliable semen PRRSV detection test. A diagnostic assay was developed based on amplification of the PRRSV RNA by reverse transcription and polymerase chain reaction (RT-PCR) followed by detection of the amplification products by hybridization and colorimetric assay in microwell plates. A highly reproducible and efficient method of viral RNA isolation from semen samples was set up. A combined RT-PCR procedure was performed, incorporating the use of uracil-N-glycosylase (UNG) in combination with dUTP instead of dTTP to prevent false positive results due to carry-over contamination. An RNA internal control was added during the RNA isolation procedure to detect false negative results. The colorimetric detection in microwell plates of amplification products from either PRRSV or IC RNA, gave specific and objective results and was automated. A cut-off value of 1000 RNA copies or 10 TCID₅₀ of PRRSV per ml of semen samples could be detected with this assay. Semen samples collected from experimentally-infected boars were tested with this assay and showed PRRSV excretion early after infection and for an extended period.

Levy, L., I.-M. Lee, et al. (1994). "Simple and rapid preparation of infected plant tissue extracts for PCR amplification of virus, viroid, and MLO nucleic acids." Journal of Virological Methods **49**(3): 295.

<http://www.sciencedirect.com/science/article/B6T96-476TY1K-5/2/7de6b4c05bc1b67103801eec2e37183f>

A rapid, simple method for preparing plant tissues infected with viruses, viroids, or MLOs using a commercial product known as Gene ReleaserTM is described. The Gene ReleaserTM polymeric matrix method produced plant extracts suitable for PCR amplification without the use of organic solvents, ethanol precipitation, or additional nucleic acid purification techniques. Modification of maceration methods and/or extraction buffers resulted in the PCR amplification of potato spindle tuber, apple scar skin, and dapple apple viroids, as well as, genomic segments of plum pox potyvirus, grapevine virus B, grapevine leafroll-associated virus III, and elm yellows MLO. These pathogens were amplified from tissue of woody and herbaceous hosts such as peach, apricot, apple, grapevine, elm, periwinkle and potato. The application of this product for use with intractable tissue avoids lengthy and laborious extraction procedures. In our hands, about 20 samples could be prepared for PCR or RT-PCR in 1-2 h versus 1-3 days.

Lewis, J. G., G.-J. Chang, et al. (1992). "Direct sequencing of large flavivirus PCR products for analysis of genome variation and molecular epidemiological investigations." Journal of Virological Methods **38**(1): 11.

<http://www.sciencedirect.com/science/article/B6T96-476RMMH-49/2/1fa0ee383a7171f49574c6fceb90f585>

The polymerase chain reaction (PCR) was used to amplify viral DNA from selected regions of dengue genomic RNA by using appropriate 'consensus' primers. DNA amplicons containing the

structural genes from all 4 dengue serotypes were prepared and directly sequenced using dengue-virus-specific primers. This method can characterize reliably flavivirus field isolates at the molecular level without extensive virus propagation and molecular cloning, and will be a valuable tool for molecular epidemiological studies.

Lindberg, A. M. and A. Andersson (1999). "Purification of full-length enterovirus cDNA by solid phase hybridization capture facilitates amplification of complete genomes." Journal of Virological Methods **77**(2): 131.

<http://www.sciencedirect.com/science/article/B6T96-3VR1B1H-3/2/d12b4eab7656f410aa9b47c4a5375c63>

The aim of the study was to develop a method for the selective purification of full-length enterovirus single strand (ss) cDNA for subsequent amplification of complete enterovirus genomes by long distance PCR. As a model system we have used the prototype strain of echovirus 5 (EV5). Due to inefficient first strand cDNA synthesis using EV5 RNA as template, only a few molecules of EV5 sscDNA were completely reverse transcribed and no amplification products were observed when long distance polymerase chain reaction (LD-PCR) was used for amplification of complete EV5 genomes. To purify the complete EV5 cDNA present, an oligonucleotide, derived from the conserved 5' end of an enterovirus genome, was immobilized on paramagnetic beads and complete EV5 sscDNA was captured and purified from the less than full-length cDNAs. LD-PCR using the purified EV5 cDNA resulted in amplification of complete EV5 genomes. Transfection of the EV5 RNA transcribed from these uncloned amplicons resulted in production of replicating viruses. This demonstrates that solid phase hybridization capture of sscDNA is an efficient method that can be used for enrichment and purification of full-length enterovirus sscDNAs.

Lindstrom, A. and J. Albert (2003). "A simple and sensitive 'in-house' method for determining genotypic drug resistance in HIV-1." Journal of Virological Methods **107**(1): 45.

<http://www.sciencedirect.com/science/article/B6T96-46YXPVK-1/2/ed6de7176e753ff6aab9650b50d5d8b6>

Antiretroviral combination therapy is a major advance in the treatment of HIV infection, but development of antiretroviral resistance is still an important cause of treatment failure. Therefore, resistance testing was recommended recently for follow-up of HIV-1 infected individuals. The aim of this study was to develop a new genotypic resistance assay because simple and affordable assays with sufficient sensitivity for different genetic subtypes and low copy number samples are still lacking. Different methods and primers for RNA extraction from plasma, cDNA synthesis, nested PCR and sequencing on an ABI310 automated sequencer were evaluated and optimised. The PCR was designed to amplify a fragment covering the protease and the first half of the reverse transcriptase (RT), which harbour most known resistance mutations to licensed antiretroviral drugs. Resistance mutations were identified using resistance analysis tools available over the Internet. The optimised assay had a sensitivity of approximately 200 RNA copies per ml. The method was evaluated on plasma samples from treated patients infected with different subtypes of HIV-1 and appeared to have similar sensitivity for all subtypes. Samples that had failed previously in routine testing were analysed successfully with the new assay. The new assay is more sensitive and robust than the current routine method.

Liu, H.-J. and J. J. Giambrone (1997). "Amplification, cloning and sequencing of the [sigma]C-encoded gene of avian reovirus." Journal of Virological Methods **63**(1-2): 203.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-1H/2/5790e7b61c10fbfb2ba8900d41488400>

The [sigma]C-encoding cDNA of avian reovirus (ARV) 1733 strain was amplified, cloned and sequenced using double nested polymerase chain reaction (PCR). The ARV [sigma]C protein is a minor component of the outer capsid that induces type-specific neutralization antibodies. Four overlapping [sigma]C-encoding cDNA fragments were obtained. Together, the four fragments represented the whole coding sequence. The nucleotide and deduced amino acid sequences of [sigma]C-encoded gene of U.S. (S1133 and 1733) and Australian isolates (RAM-1 and SOM-4) were compared. The U.S. isolates were closely related, but different from Australian isolates. The degree of differences between the U.S. and Australian isolates was over 44.89% at both the nucleotide and deduced amino acid levels and suggested that the virus is evolving separately in different continents. The deduced amino acid sequences of ARV [sigma]C indicated a heptapeptide repeat in the N-terminal region of ARV [sigma]C existed in all ARVs. The results suggested that ARV [sigma]C is structurally related to mammalian reovirus (MRV) [sigma]1.

Liu, H.-J., J. J. Giambrone, et al. (1994). "Detection of genetic variations in serotype I isolates of infectious bursal disease virus using polymerase chain reaction and restriction endonuclease analysis." Journal of Virological Methods **48**(2-3): 281.

<http://www.sciencedirect.com/science/article/B6T96-476F6FR-F0/2/8d9eb2293f30db9da00d0aad2bf7aab>

Reverse transcription with polymerase chain reaction (PCR) followed by restriction endonuclease analysis detected genetic variations among serotype I isolates of infectious bursal disease virus (IBDV). Using a set of synthetic primers derived from the large genome segment of APHIS-IBDV, the hypervariable region (AccI-SpeI fragment) located in the VP2 gene was amplified. With all strains, a cDNA fragment of approximately 643 bp was amplified, indicating that there were no apparent deletions or insertions in this region among isolates. Fragments amplified from 9 isolates were digested with 14 restriction enzymes. Restriction fragment profiles generated by restriction enzymes NaeI, StuI, TaqI, and SacI, showed genetic variations among isolates. This study provided a simple and sensitive method for detection of genetic variations among isolates that are closely related serologically and could not be differentiated using current serologic methods.

Liu, H. J., J. J. Giambrone, et al. (1997). "Molecular characterization of avian reoviruses using nested PCR and nucleotide sequence analysis." Journal of Virological Methods **65**(2): 159.

<http://www.sciencedirect.com/science/article/B6T96-3RJG407-3/2/71d5c699c9ae427595bd1952d9d58c72>

A nested polymerase chain reaction (PCR) with subsequent nucleotide sequence analysis identified and differentiated avian reoviruses (ARVs). PCR products amplified from the S1 gene segment of ARV of USA isolates were 738 and 342 bp, respectively. PCR products were confirmed by Southern and dot blot hybridizations. The amplified cDNA fragments were cloned into the pUC18 vector and subjected to DNA sequencing. The nucleotide and deduced amino acid sequences of four USA (S1133, 1733, 2408, and CO8) and two Australian isolates (RAM-1 and SOM-4) were compared. Results of paired difference analysis and a predicted dendrogram

revealed that USA isolates were closely related, but different from, Australian isolates. The deduced amino acid sequences of the N-terminal region of ARV [sigma]C showed a heptapeptide repeat of hydrophobic residues in all ARV isolates.

Lokensgard, J. R., D. G. Thawley, et al. (1991). "Enzymatic amplification of latent pseudorabies virus nucleic acid sequences." Journal of Virological Methods **34**(1): 45.

<http://www.sciencedirect.com/science/article/B6T96-476RM08-6/2/71eb01468a54bc451de3ccf8eb88addf>

To investigate various aspects of the latency of pseudorabies virus in swine (PRV, suid herpesvirus 1) we developed in vitro nucleic acid amplification methods based upon the polymerase chain reaction. Primers flanking a 156-bp region of the pseudorabies virus gp II gene were annealed to purified PRV DNA as well as DNA isolated from the trigeminal ganglia of swine latently infected with PRV and subjected to PCR amplification. Following amplification, 100 fg of PRV DNA was visualizable on stained gels and 1 fg (equivalent to 6 viral genome copies) was detectable when amplification was combined with blot hybridization. PRV-specific DNA sequences which remained undetectable by direct blot hybridization assays were amplified to levels visualizable on ethidium-bromide-stained gels in 5 of 5 experimental latently infected animals. In addition, oligonucleotide primers specific for a 223-bp region of the PRV immediate-early gene (IE 180) were capable of amplifying overlapping latency associated transcripts (LATs), via a cDNA intermediate, in 6 of 6 latently infected swine. These nucleic acid amplification methods should be applicable to the investigation of PRV latency, and gene expression during latency and reactivation, in which few cells harbor latent virus.

Lovatt, A., J. Black, et al. (1999). "High throughput detection of retrovirus-associated reverse transcriptase using an improved fluorescent product enhanced reverse transcriptase assay and its comparison to conventional detection methods." Journal of Virological Methods **82**(2): 185.

<http://www.sciencedirect.com/science/article/B6T96-3XT0BN2-B/2/296d10f4df7d1baea340b4627345daf3>

The development and application of a novel, sensitive TaqMan fluorescent probe-based product enhanced RT test (F-PERT) for the detection of retrovirus are described. The assay allows discrimination between the amplification signals generated by genuine positive signals that result from retroviral RT activity and the RT-like activity from DNA polymerases. The RT-like activity from DNA polymerases was suppressed by the addition of activated calf-thymus DNA with no reduction in the RT activity. A linear relationship between threshold cycle (CT) and the number of virus particles was demonstrated, allowing quantification of retroviruses in unknown samples. The F-PERT assay was able to detect a wide range of retroviral RT activities, including that from porcine endogenous retrovirus (PoERV), murine leukaemia virus (MLV), simian foamy virus (SFV), simian immunodeficiency virus (SIVmac) and squirrel monkey retrovirus (SMRV). The detection limit of SMRV, MLV and PoERV was approximately 100 virion particles and the test was able to detect at least 102 molecules of purified RT enzyme. RT activity was not detected in cellular lysates and supernatants from MRC-5, BT, VERO, or Raji cells, whereas RT activity was detected in C1271, Mus dunni, K-Balb, BHK-21, CHO-K1, SP2/0-Ag14 and NSO cell supernatants. RT activity was also detected in the Spodoptera cell line Sf9.

M. Shamloul, A., N. A. Abdallah, et al. (2001). "Sensitive detection of the Egyptian species of sugarcane

streak virus by PCR-probe capture hybridization (PCR-ELISA) and its complete nucleotide sequence." Journal of Virological Methods **92**(1): 45.

<http://www.sciencedirect.com/science/article/B6T96-427JWSG-6/2/bb1896ce52bc9d2c82bef67844bcb837>

A rapid and sensitive assay for the specific detection of Sugarcane streak virus (SSV) using PCR-probe capture hybridization (PCR-ELISA) was developed. Nucleic acids suitable for PCR were extracted from SSV-infected tissue using organic solvents or Fast DNA kit. SSV cDNA was amplified using viral specific primers and the amplified SSV cDNA (amplicon) was DIG-labelled during the amplification process. The amplicon was then detected in a colorimetric hybridization system by a microtiter plate using a biotinylated cDNA (22 nt), cDNA (789 nt) or cRNA (789 nt) capture probe. This system combines the specificity of molecular hybridization, the ease of the colorimetric protocol, and is 10-100 fold more sensitive than agarose gel electrophoretic analysis in detecting the amplified product. Long cDNA or cRNA capture probe was 2-7 fold more sensitive than the oligo cDNA probe for the detection. Complete nucleotide sequence of SSV from Naga Hammady, Egypt, revealed that SSV-EG is a new species of SSV that shares 66% nucleotide identity with the virus species from Natal, South Africa.

Mackie, N., S. Dustan, et al. (2004). "Detection of HIV-1 antiretroviral resistance from patients with persistently low but detectable viraemia." Journal of Virological Methods **119**(2): 73.

<http://www.sciencedirect.com/science/article/B6T96-4C76GN5-2/2/f048012db030a1f2adef5984b4777052>

We modified the Abbott diagnostics HIV-1 Viroseq version 2 assay(TM) in order to detect the presence of HIV-1 drug resistance mutations in patients with viraemia below 1000 copies/ml of plasma. One hundred and forty-four patients with a detectable HIV-1 plasma viral load below 1000 copies/ml were selected and HIV-1 genetic analysis carried out using a modification of the Abbott Diagnostics Viroseq 2.0 assay(TM). The procedure differs from the standard protocol in that a nested PCR amplification step was introduced. The oligonucleotide primers for the first round of PCR were those supplied in the RT-PCR module of the kit. The nested PCR primers were primers A and H taken from the sequencing module. One hundred and twenty-eight out of 144 (89%) plasma samples with an HIV-1 viral load of less than 1000 copies/ml (ranging from 54 to 992 copies) were successfully sequenced. HIV-1 genotypes were obtained from 68 out of 81 (84%) samples with a viral load of greater than 50 but less than 300 copies/ml and 60/63 (95%) of samples with a viral load of greater than 300 but less than 1000 copies/ml. Serial dilution of a sample with a high viral load did not affect the detection of resistance mutations. Multiple sequencing of samples with low viral load did not result in detection of additional mutations, although, in one sample the K103N mutation was detected in 3/6 replicates while wild-type was detected in 2/6 and a mixture of wild-type/mutant in 1/6. Samples from patients infected with both clade B and non-B clades of HIV-1 could be genotyped at low copy number. Modification of the Abbott Viroseq assay allows reproducible sequencing of the HIV-1 genome from patients with low, but detectable, plasma virus burden.

Malet, I., M. Belnard, et al. (2003). "From RNA to quasispecies: a DNA polymerase with proofreading activity is highly recommended for accurate assessment of viral diversity." Journal of Virological Methods **109**(2): 161.

<http://www.sciencedirect.com/science/article/B6T96-4891C2T-1/2/71eda00073c8b9f038aed98b0ec9c9a5>

RNA viruses are characterized by their high rates of genetic variation. Their genetic diversity is generally studied by reverse transcription (RT) followed by polymerase chain reaction (PCR) amplification and nucleotide (nt) sequence determination. The misinterpretation of viral diversity due to copy errors introduced by the enzymes used in this two-step protocol has not yet been assessed systematically. In order to investigate the impact of such errors, we sought to bypass the intrinsic viral heterogeneity by starting from a homogeneous cDNA template. With this in mind, the hepatitis C virus (HCV) 5' non-coding region (5'NCR) was amplified either by PCR starting from a homopolymeric cDNA template or by RT-PCR starting from the in vitro RNA transcript derived from the same original cDNA template. Amplicons were cloned and the 17-20 individual clones were sequenced in each assay. Different quasispecies patterns were obtained with various commercially available DNA polymerases, resulting in different computed error rates. The non-proofreading Taq DNA polymerase provided the highest error rate which was seven times higher than that obtained with the most reliable of the proofreading polymerases tested. We, therefore, emphasize that the misleading interpretation of the observed heterogeneity for a given viral sample could be due to ignorance of the fidelity of the polymerase used for viral genome amplification, and thus that proofreading DNA polymerases should be preferred for the investigation of natural genetic diversity of RNA viruses.

Malmstrom, C. M. and R. Shu (2004). "Multiplexed RT-PCR for streamlined detection and separation of barley and cereal yellow dwarf viruses." Journal of Virological Methods **120**(1): 69.

<http://www.sciencedirect.com/science/article/B6T96-4CPM5P6-1/2/ae2085cad0e040878f54f4f6c0a38ab2>

Two novel multiplexed RT-PCR assays that can efficiently detect and distinguish among different barley and cereal yellow dwarf viruses (B/CYDVs) are described. The basic multiplex can produce two fragments simultaneously, a ~830-bp fragment indicating the presence of the BYDV-PAV, BYDV-MAV, or BYDV-SGV viruses and a ~372-bp fragment indicating the presence of the CYDV-RPV, BYDV-RMV, or BYDV-GPV viruses. The enhanced multiplex produces two additional fragments, which further differentiate between BYDV-PAV, BYDV-MAV, and BYDV-SGV. These assays fulfill the critical need for a streamlined diagnostic procedure for B/CYDVs that can be cost-effectively applied to large numbers of small samples. The assays are useful not only in the basic diagnosis of B/CYDVs, but also for studies examining the ecological roles of B/CYDVs in natural systems and for longer-term epidemiological studies of grasses and cereals.

Markowski-Grimsrud, C. J., M. M. Miller, et al. (2002). "Development of strain-specific real-time PCR and RT-PCR assays for quantitation of chicken anemia virus." Journal of Virological Methods **101**(1-2): 135.

<http://www.sciencedirect.com/science/article/B6T96-44M2HSJ-1/2/d513f8604d65fa9a9d84899d6a894076>

Chicken anemia virus (CAV) is a ubiquitous pathogen of poultry. A CAV specific TaqMan(TM)-based PCR and RT-PCR assay for real-time quantitation of viral load and relative quantitation of virus-specific transcript levels was developed. Detection of viral DNA copy number from infected MDCC-CU147 cells was determined by extrapolation from a CAV plasmid-based standard curve. Viral load increased proportionally with increasing cell number harvested, increasing from 4 x 10² copies in 250 cells with 38% virus positive cells in an indirect immunofluorescence assay to 8 x 10⁵ copies in 250,000 cells with 64% infected cells. The estimated average viral copy number per infected cell ranged from 5 to 14. Strain-specific primers were developed to distinguish between the Cux-1 and CIA-1 strains of CAV. These primers exhibited a 3 to 4 log differential in amplification comparing homologous versus heterologous virus-primer combinations. The

sensitivity of the real-time assay was found to be comparable to a nested PCR assay using DNA samples from a SPF poultry flock exposed to the SH-1 strain of CAV. The real-time PCR detected from 1.7 to 4.2 target molecules in three out of four samples that were positive by nested PCR using 50% of the DNA used in the nested PCR. Relative viral transcript levels for Cux-1 and CIA-1 infected cell cultures increased proportionally with increasing cell numbers harvested for RNA extraction. This assay will be important for both diagnosis and in understanding the complex pathogenesis of CAV infection.

Marshall, R. L., J. Cockerill, et al. (1998). "Detection of GB virus C by the RT-PCR LCx(R) system." Journal of Virological Methods **73**(1): 99.

<http://www.sciencedirect.com/science/article/B6T96-3T2PCND-F/2/a71c64db59aa0681dd9f0a9d2c65d436>

The recent publication of representative genomic sequences of GBV-C has permitted the selection of PCR primers for detection of GBV-C in clinical samples by PCR techniques. Traditional amplification methodologies which couple reverse transcription polymerase chain reaction (RT-PCR) and Southern blot detection are slow, cumbersome, and can be technique dependent. This has hampered studies to determine the clinical significance of GBV-C. We report the selection of highly conserved PCR primers and a probe useful for semi-automated RT-PCR using the Abbott LCx(R) system. This adaptation of the LCx(R) system expands its capabilities to include the detection of RNA by RT-PCR, in addition to DNA detection by ligase chain reaction (LCR).

Maudru, T. and K. Peden (1997). "Elimination of background signals in a modified polymerase chain reaction-based reverse transcriptase assay." Journal of Virological Methods **66**(2): 247.

<http://www.sciencedirect.com/science/article/B6T96-3RYCMYM-B/2/e6c2f0bca9b23a5dc1daf372cf6bedd1>

Three highly sensitive reverse transcriptase (RT) assays were recently published that are at least one million times more sensitive than conventional RT assays. These assays derive their high sensitivities through the ability to amplify the complementary DNA (cDNA) product of the RT reaction by the polymerase chain reaction (PCR). We describe a modified PCR-based RT (PBRT) assay that retains the high sensitivities of the original assays while reducing their inherent background signals. The background signal of the PBRT assay was found to be due to an intrinsic RNA-dependent DNA polymerase activity of the Taq DNA polymerase, the enzyme used for the PCR. It could be eliminated by inserting a ribonuclease digestion step prior to amplifying the cDNA product of the RT reaction by PCR and by using a thermostable DNA polymerase identified as having reduced RNA-dependent DNA polymerase activity. Comparable results were obtained using three RNA templates with two purified RT enzymes. This modified assay is capable of detecting reliably between 10 and 100 molecules of RT, which is equivalent to between 1 and 10 retrovirus particles.

Maunula, L., H. Piiparinen, et al. (1999). "Confirmation of Norwalk-like virus amplicons after RT-PCR by microplate hybridization and direct sequencing." Journal of Virological Methods **83**(1-2): 125.

<http://www.sciencedirect.com/science/article/B6T96-3XVPG88-G/2/8c72d648973bd6cfe8fc00cef880ed9b>

A large number of Norwalk-like viruses (NLVs) have been identified from stool samples by RT-PCR by amplifying part of the polymerase-coding gene. A set of probes were selected based on sequence analysis of the viruses circulating in Finland during the years 1996-97 for confirmation of the findings by hybridization. A microplate hybridization test, which provides a rapid semi-automatic detection for PCR products, was designed and compared with agarose gel electrophoresis. From the material of 210 stool samples, mainly from diarrheal outbreaks during years 1997-1998, three probes, one for NLV genogroup GGI and one for each of the two GGII subgroups (Toronto-like and Lordsdale-like), were sufficient to detect 87.8% (36/41) of GGI and 89.0% (49/55) of GGII samples positive by gel electrophoresis. Amplicon sequencing of the strains not detected by the above probes revealed genetic variability in the sequences. Biotin-streptavidin binding was used both for microplate hybridization assays and for direct sequencing to identify the amplicons. Based on the sequences three more probes for the hybridization panel were added so that all the different NLVs of this study could be recognized.

McCann, S. H. E., J. A. Mumford, et al. (1995). "Development of PCR assays to detect genetic variation amongst equine herpesvirus-1 isolates as an aid to epidemiological investigation." Journal of Virological Methods **52**(1-2): 183.

<http://www.sciencedirect.com/science/article/B6T96-3YXC151-14/2/3040affac2accaa52598832be6104e5f>

A search for variable restriction sites has been carried out for equine herpesvirus-1 (EHV-1) in an attempt to develop markers which can be used to group epidemiologically related viruses into groups, and to learn more about the dynamics of EHV-1 disease. Crude viral DNA extracts of EHV-1, prepared by Hirt extraction, were digested with AluI, HaeIII, or RsaI, and Southern blotted following electrophoresis. DNA fingerprints, produced by probing the Southern blots with the EHV-1 EcoR1-I fragment, separated 56 isolates into 16 groups. The variable sites within the EcoR1-I fragment were mapped approximately using fragments from within EcoR1-I, and the precise location of the variable sites determined from the DNA sequence of this fragment. Oligonucleotide primers flanking the variable sites were synthesized, and used in PCR assays to detect variable fragments. The AluI variable fragment was found to result from the presence or absence of a single AluI site. In contrast, the variable bands seen with HaeIII and RsaI, resulted from variation in the copy number of two tandemly repeated sequences, one of which had not previously been recognized. In addition, HaeIII digests of EHV-1 isolates probed with the glycoprotein B (gB) gene of EHV-1 also separated isolates into two groups. The variable HaeIII site was mapped towards the 5'-end of the gB gene and a PCR assay established. The distribution of the variable AluI site within the EcoR1-I fragment and the HaeIII site within the gB gene were estimated on a large number of clinical isolates using PCR on unpurified viral tissue culture medium. Both sites had a good distribution and together with additional variable sites should provide the basis for the rapid DNA fingerprinting of EHV-1 isolates.

McElhinney, L. M., R. J. Cooper, et al. (1995). "Multiplex polymerase chain reaction for human herpesvirus-6, human cytomegalovirus, and human [beta]-globin DNA." Journal of Virological Methods **53**(2-3): 223.

<http://www.sciencedirect.com/science/article/B6T96-3YYT72B-6/2/4f1f27b6af10e0e75dc01add9b99589d>

Human cytomegalovirus and human herpesvirus-6 are closely related viruses which cause similar diseases, have similar cellular repositories of latent infection, and may be detected largely in the same types of clinical specimens. DNA amplification appears likely to play an increasing role in the diagnosis of recent and remote infection with these agents. A sensitive multiplex polymerase

chain reaction was therefore developed for the two viruses and for human [beta]-globin DNA. Optimization of parameters such as the primers, primer concentrations, magnesium concentration, and buffer constituents was crucial in achieving a sensitive assay. Preliminary results indicated that the assay could simultaneously monitor DNA extraction from clinical specimens and allow detection of HCMV or HHV-6 in patients with diseases possibly caused by either pathogen.

Merel, P., I. Pellegrin, et al. (2001). "Comparison of capillary electrophoresis sequencing with the new CEQ 2000 DNA Analysis System to conventional gel based systems for HIV drug resistance analysis." Journal of Virological Methods **98**(1): 9.

<http://www.sciencedirect.com/science/article/B6T96-43VYKRP-2/2/a74ac886f6d28b6e5d854150025656d1>

To date the majority of sequencing technologies have been based on use of gel plates. In this study sequencing by capillary electrophoresis for HIV-1 genotyping on the CEQ 2000 sequencer (Beckman Coulter Inc.) has been investigated and compared to an 'in house' protocol on the Prism-377 sequencer (Applied Biosystems) and to the HIV-1 TruGene kit (Visible Genetics Inc.), two gel plate-based systems. Plasma from 20 HAART-treated patients with virological failure were analyzed for protease (PR) and reverse transcriptase (RT) genes. A total of 520 RT codons (26/patient) and 360 PR codons (18/patient) related to antiretroviral drug resistance were evaluated. The overall agreement between CEQ 2000 and Prism-377 results was 100% for the RT and PR primary and secondary mutations. The overall agreement between CEQ 2000 and TruGene was 100% for primary and $\geq 97\%$ for secondary mutations. Discrepant results would have never led to errors in genotype interpretation. Performances for a 24 patients/week/one technician genotyping throughput were analyzed. For Prism-377, TruGene and CEQ 2000, manual processing required 5, 4 and 2,5 days, sequence data analysis needed additional 3, 1 and 2 days and cost/patient was [ap]49, 214 and 39 \$, respectively. The CEQ 2000 sequencer offers a reliable alternative for fast and cost effective HIV drug resistance analysis.

Merzouki, A., T. Mo, et al. (1994). "Accurate and differential quantitation of HIV-1 tat, rev and nef mRNAs by competitive PCR." Journal of Virological Methods **50**(1-3): 115.

<http://www.sciencedirect.com/science/article/B6T96-47DKYF8-D/2/61a9db200bf9c6c8d8b4202c283ebd1c>

An accurate method is described for measuring the relative abundance of HIV-1 regulatory mRNAs directly in clinical specimens. Specimen RNA is reverse transcribed and coamplified with a common competitor containing tat, rev and nef internal standards using fluorescent primers and a competitive polymerase chain reaction. After amplification, individual products are separated and analyzed on a fluorescent DNA sequencer. Using this approach, it was possible to measure reproducibly two-fold differences in the relative abundance of mRNAs with coding potential for tat, rev and nef from as little as 0.2 ng of total RNA extracted from peripheral blood mononuclear cells of HIV-1 infected persons. The ratio method eliminates the need to account for variability in RNA recovery during sample processing and provides a powerful tool for measuring the differential expression of HIV-1 regulatory genes in vivo.

Meyer, R. F., G. D. Babcock, et al. (1997). "Baculovirus expressed 2C of foot-and-mouth disease virus has the potential for differentiating convalescent from vaccinated animals." Journal of Virological

Methods **65**(1): 33.

<http://www.sciencedirect.com/science/article/B6T96-3XY8R56-5/2/1ebf5bcac2100792c58b962740a63853>

Determining whether animals have been infected with foot-and-mouth disease virus or vaccinated is important because infected animals frequently become carriers of the virus, shed it intermittently and thus may be the source of new outbreaks of the disease. We had shown previously that the sera of convalescent animals contain antibodies to 2C, a highly conserved non-structural protein, whereas the sera of vaccinated animals do not. This is explained by the observation that 2C is retained on the membranes of cells used for growing the virus for vaccine production. In contrast, the non-structural protein 3D, which is released into the medium, is not removed by centrifugation or filtration during vaccine production and therefore stimulates an immune response in both vaccinated and convalescent cattle. In this study we produced 2C and 3D in insect cells infected with recombinant baculoviruses. As demonstrated by serology and electron microscopy, 2C is also retained on the membranes of the insect cells. Both expressed proteins react with sera of convalescent animals, indicating that they are conformationally similar, but the 2C does not react with sera from vaccinated animals. The baculovirus expressed 2C appears to be a suitable antigen for the development of a reliable diagnostic test.

Michael Lindberg, A., C. Polacek, et al. (1997). "Amplification and cloning of complete enterovirus genomes by long distance PCR." Journal of Virological Methods **65**(2): 191.

<http://www.sciencedirect.com/science/article/B6T96-3RJG407-6/2/fdeb3a40c6bc05cca66145b20fac4d7e>

A method for amplification and cloning of complete enterovirus cDNA genomes is described. Viral RNA was reverse transcribed using an optimized protocol and a reverse transcriptase with reduced RNase H activity. Amplicons corresponding to complete genomes of 14 prototype strains of group B coxsackieviruses and echoviruses were amplified using oligonucleotide primers derived from the Coxsackievirus B3 genomic sequence of the 5' and 3' ends and a mixture of thermostable DNA polymerases. Coxsackievirus B2 amplicon was then cloned and the terminal sequences of the insert were determined. Lipofection of individual clones resulted in productive Coxsackievirus B2 infection. The method described makes it possible to obtain large amounts of complete enterovirus cDNAs and simplifies the construction of infectious full-length cDNA clones. Successful amplification of all enterovirus prototype strains tested emphasizes the general use of the method described, which provides a rapid and efficient alternative to traditional cloning strategies.

Moen, E. M., J. Sleboda, et al. (2002). "Real-time PCR methods for independent quantitation of TTV and TLMV." Journal of Virological Methods **104**(1): 59.

<http://www.sciencedirect.com/science/article/B6T96-45CDM11-3/2/bf814f74647b9e35a57695929170d5be>

There is considerable interest in the possible clinical effects of the human circoviruses TT virus (TTV) and TTV-like mini virus (TLMV). Most people appear to have at least one of these viruses replicating actively in their bodies, thus mere correlation of the presence of virus and disease states are probably less informative than a quantitative analysis of viraemia. Real-time PCR based methods, with either SYBR Green or TaqMan probe, designed to quantitate selectively TTV and TLMV are described. The suggested TaqMan-based protocols were suitable for

quantitation of viruses in the range of 102-109 copies/ml of sample; and proved, by sequencing of PCR products, to be specific for each of the two viruses.

Molitor, T. W., K. Oraveerakul, et al. (1991). "Polymerase Chain Reaction (PCR) amplification for the detection of porcine parvovirus." Journal of Virological Methods **32**(2-3): 201.

<http://www.sciencedirect.com/science/article/B6T96-476KXFR-J7/2/5edd0839b161e30756147ad9d8ea6e68>

A polymerase chain reaction (PCR) amplification method was developed and evaluated to detect porcine parvovirus (PPV). A pair of 20-base primers and an oligonucleotide probe were derived from the DNA sequences common to two isolates of PPV, NADL-8 and NADL-2. The primers flanked 118-bp nucleotides within the region coding for the major structural protein VP2. After DNA amplification of PPV replicative form (RF), a 158-bp fragment was detected in agarose gels. This amplified fragment was shown to be specific for PPV DNA after Southern transfer and hybridization to a 20-base internal probe. The amplified fragment also contained a single EcoRI cleavage site. Various conditions, such as number of cycles and annealing temperature, were examined to optimize the conditions for detecting viral DNAs from infected cell cultures and swine fetal tissues. Four different isolates of PPV, NADL-8, NADL-2, KBSH and Kresse, and two other viruses, canine parvovirus (CPV) and pseudorabies virus (PRV), were included to determine specificity of amplification. Slot blot hybridization with a radiolabeled probe was used to evaluate the sensitivity of PCR amplification. The optimized protocol was specific for PPV detecting equally all four strains of PPV, but failing to amplify CPV or PRV sequences. The PCR method could detect at least 100 fg of viral replicative form (RF) DNA or the equivalent of 1 PFU of infectious virus. The applications of this method include routine detection of PPV in clinical samples and as a contaminant in mammalian cell lines.

Naito, H. and K. Abe (2001). "Genotyping system of GBV-C/HGV type 1 to type 4 by the polymerase chain reaction using type-specific primers and geographical distribution of viral genotypes." Journal of Virological Methods **91**(1): 3.

<http://www.sciencedirect.com/science/article/B6T96-426XYK0-J/2/e597903a5704609ffee9fb685bbe6a9b>

Based on variation in nucleotide sequence of 5'-untranslated region, GB virus type C (GBV-C) and hepatitis G virus (HGV) can be classified into three major genotypes. In addition to this classification, a novel genotype of GBV-C/HGV was identified and designated type 4. However, genotyping of GBV-C/HGV has been hampered by the lack of suitable assays. In this study, a simple and precise genotyping system based on PCR using the type-specific primers was developed for the determination of genotypes 1, 2, 3, and 4 of GBV-C/HGV. A total of 235 serum samples obtained from 11 different countries were tested by our PCR genotyping system of GBV-C/HGV. The results revealed that type 1 was prevalent mainly in Ghana, type 2 was prevalent in the USA, Spain, Egypt, Nepal and Myanmar, type 3 was prevalent in Japan and Bolivia, and type 4 was prevalent in Vietnam and Myanmar among the countries investigated in the present study. To confirm the specificity of the results of genotyping by PCR, phylogenetic analysis in the 5'-untranslated region of GBV-C/HGV was undertaken in 99 serum samples. By this analysis, the specificity of the genotyping system by PCR was confirmed. This assay system may be useful for rapid typing of GBV-C/HGV RNA when either epidemiological or transmission studies of this agent are carried out.

Najioullah, F., D. Thouvenot, et al. (2001). "Development of a real-time PCR procedure including an internal control for the measurement of HCMV viral load." Journal of Virological Methods **92**(1): 55.

<http://www.sciencedirect.com/science/article/B6T96-427JWSG-7/2/1e33f8b1e295ab442ae4f648e13142ed>

Human cytomegalovirus (HCMV) infections are frequent in immuno-compromised patients. The recent development of real-time PCR procedures that allow the rapid quantification of genome load will be helpful for accurate monitoring of these infections. Two extraction procedures were evaluated using 30 blood samples that were processed pure and diluted (1/10). Repeatability and reproducibility of the quantitative PCR procedure using an internal control for amplification were analysed, and its sensitivity compared to a qualitative PCR procedure using 50 HCMV culture positive blood samples. The real-time PCR and qualitative PCR procedures were positive in 46 and 48 of the samples tested, respectively. Discrepancies were observed for samples with a low viral load. The sensitivity of the real-time PCR procedure was evaluated at 500 HCMV DNA copies per ml of sera. The use of an internal control concomitantly processed during the HCMV quantification did not alter the sensitivity of the procedure, and was relevant for the detection of putative PCR inhibitors that may interfere with the amplification process. This procedure was used to measure genome load in two bone marrow transplant patients with HCMV disease, confirming that this new PCR procedure should be used widely for diagnosing and monitoring HCMV infections in transplant patients.

Navas-Castillo, J., J. A. Diaz, et al. (1998). "Improvement of the print-capture polymerase chain reaction procedure for efficient amplification of DNA virus genomes from plants and insect vectors." Journal of Virological Methods **75**(2): 195.

<http://www.sciencedirect.com/science/article/B6T96-3V5F5S6-7/2/ed24dcf3583c7e7ab5354f937afafa05>

A rapid and simple procedure is described to amplify efficiently geminivirus DNA genomes by improving the print-capture polymerase chain reaction (PCR) procedure reported recently for RNA viruses. This method, termed print-PCR (P-PCR), allows direct amplification of DNA from infected plant or whitefly tissues printed directly on Whatman 3MM paper, without the need of any grinding, incubation, or washing steps previous to the amplification reaction. P-PCR reduces sample manipulation and avoids previous extraction of nucleic acids, thereby diminishing the possibilities of cross-contamination between samples. P-PCR has been successfully applied to whiteflies and various plant species infected by two different tomato yellow leaf curl viruses, TYLCV-Sr and TYLCV-Is, and for the amplification of the full-length genome of TYLCV-Is from infected plants.

Nemchinov, L. and A. Hadidi (1998). "Specific oligonucleotide primers for the direct detection of plum pox potyvirus-cherry subgroup." Journal of Virological Methods **70**(2): 231.

<http://www.sciencedirect.com/science/article/B6T96-3SBVX4H-F/2/99c020d48a0c46e673cc680cfae9648c>

A specific polymerase chain reaction assay was developed for direct identification of the distinct subgroup of plum pox potyvirus (PPV) isolates from cherry trees (PPV-cherry, PPV-C) and its differentiation from other known subgroups of PPV. The specificity of the assay is based on using a pair of primers whose nucleotide sequences are located on the coat protein gene of PPV-sour

cherry (SoC) at regions of high nucleotide divergence between PPV-SoC and other isolates of PPV. The technique will be useful for studying the epidemiology of PPV-C as well as for practical testing in certification and quarantine programs worldwide.

Nie, X. and R. P. Singh (2002). "A new approach for the simultaneous differentiation of biological and geographical strains of Potato virus Y by uniplex and multiplex RT-PCR." Journal of Virological Methods **104**(1): 41.

<http://www.sciencedirect.com/science/article/B6T96-45CDM11-1/2/8361a181eef499c15344058b0eeb8ba3>

Two strains of Potato virus Y (PVY), the common (PVYO) and the tobacco vein necrosis (PVYN) have been known for decades. More recently, a tuber ringspot necrosis (PVYNTN), and several recombinants of PVYO and PVYN (designated here as PVYN:O) have been described. Further, the PVYN group of strains have been assigned to two geographical subgroups of European (EU) PVYN/NTN and the North American (NA) PVYN/NTN. The evolution of new PVYN strains, has complicated the diagnosis, which requires a combination of bioassay, serological and molecular assays. To simplify the identification and differentiation of various PVYN strain groups, a competitive (single antisense and multiple sense primers) reverse transcription-polymerase chain reaction (RT-PCR) was used, making use of minor differences in the variable region part of the PVY genome. Specifically, primers based on small variations in nucleotide stretches of P1 gene permitted a broad range separation of PVYO and PVYN groups and the specific detection of strain subgroups. The primer pairs designed for identifying PVYO, EU-PVYN/NTN, NA-PVYN and NA-PVYNTN are described. Primer pairs can be used in a uniplex (single pair of primer) or multiplex (duplex, tetraplex or pentaplex) competitive RT-PCR, allowing simultaneous testing for any combination of PVYO, EU-PVYN/NTN, NA-PVYN and NA-PVYNTN.

Nie, X. and R. P. Singh (2001). "A novel usage of random primers for multiplex RT-PCR detection of virus and viroid in aphids, leaves, and tubers." Journal of Virological Methods **91**(1): 37.

<http://www.sciencedirect.com/science/article/B6T96-426XYK0-P/2/e3a672edc650138234f031d660a2841f>

A multiplex reverse transcription polymerase chain reaction (m-RT-PCR) was developed for the simultaneous detection of five potato viruses and a viroid. The synthesis of cDNAs used for amplification was primed by hexanucleotides (random primers, RP). An RNA extraction procedure employing DNase I, is routinely used to isolate potato viruses and viroid (Potato virus S, PVS; Potato leafroll virus, PLRV; Potato virus X, PVX; Potato virus A and Y, PVA, PVY; and Potato spindle tuber viroid, PSTVd) from infected tissues. This extraction method produced deoxy-oligonucleotides, which in turn were used to prime the reverse transcription of RNA templates of all the viruses and the viroid. A time-course study from 15 s to 30 min showed optimal oligonucleotide generation by DNase I occurred at 10 min, an incubation time already incorporated in the extraction protocol. The presence of oligonucleotides capable of priming cDNA synthesis was also demonstrated in RNA preparations from aphids, leaves, and tubers. In order to duplicate the priming of templates by oligonucleotides, commercially available hexanucleotides were used as RP. When fragments were amplified from 5'- and 3'-ends of the random primed cDNA of PVY genome, bands of similar intensity were observed. In contrast, when two fragments (short and long) from the P1 gene region of the PVA genome were amplified, the yield of the short fragment was significantly higher in intensity than that of the long fragment in random primed cDNA. Irrespective of the origin of the primers (generated during extraction vs. commercially purchased), single or multiple viruses or the viroid were detected by amplification of random primed cDNAs present individually in the reaction or in a cDNA pool consisting of five

viruses and the viroid. The cDNA produced by RP or virus specific primers (SP) was used to detect PLRV and PVY from infected tubers in a duplex reverse transcription polymerase chain reaction (d-RT-PCR). The RP cDNA gave increased detection. Comparison of RP primed cDNAs from dormant or sprouted tubers and leaves showed that for some cultivars, such as 'Shepody', leaves were more reliable for PVY and PLRV detection than the tubers, in both the d- and m-RT-PCR.

Njouom, R., C. Pasquier, et al. (2003). "Assessment of HIV-1 subtyping for Cameroon strains using phylogenetic analysis of pol gene sequences." Journal of Virological Methods **110**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-488G8YB-3/2/3a9299f22aaf60d094f4d445fdd214ca>

Phylogenetic analysis of human immunodeficiency virus type 1 (HIV-1) pol gene is a useful method for subtyping European strains of HIV-1. The suitability of this method for genetically diverse African strains was evaluated by comparing HIV-1 subtyping of Cameroon strains using a long fragment of the pol gene sequence to the findings obtained using env gene sequences. When the pol gene could not be amplified, the reverse transcriptase (RT) or the protease (PR) genes were used. Phylogenetic analysis of the env C2/V3 gene sequences of 60 HIV-1 isolates showed 52 to be subtype A, 2 subtype G, plus one each of subtypes C, F2 and H, with 3 subtypes not determined. A long fragment of the pol gene was amplified successfully and sequenced in 23% of cases. The RT region was amplified for 42% of the samples that could not be typed by analysing the long fragment, and the PR gene was amplified for 40% of them. Thus, 63% of samples were typable. Env and pol gene subtypings were in agreement in 86% of cases. It is concluded that the phylogenetic analysis of pol gene sequences is not a practical method for HIV-1 subtyping in areas of high subtype diversity, despite the good agreement between the env and pol gene subtypings. However, it can be a useful method for HIV-1 subtyping, provided that the gene is amplifiable.

Nuanualsuwan, S. and D. O. Cliver (2002). "Pretreatment to avoid positive RT-PCR results with inactivated viruses." Journal of Virological Methods **104**(2): 217.

<http://www.sciencedirect.com/science/article/B6T96-45WGH3G-2/2/8fd0074a4e4ba9f4f3c80b21156d2545>

Enteric viruses that are important causes of human disease must often be detected by reverse transcription-polymerase chain reaction (RT-PCR), a method that commonly yields positive results with samples that contain only inactivated virus. This study was intended to develop a pretreatment for samples, so that inactivated viruses would not be detected by the RT-PCR procedure. Model viruses were human hepatitis A virus, vaccine poliovirus 1 and feline calicivirus as a surrogate for the Norwalk-like viruses. Each virus was inactivated (from an initial titer of [ap]103 PFU/ml) by ultraviolet light, hypochlorite or heating at 72 [deg]C. Inactivated viruses, that were treated with proteinase K and ribonuclease for 30 min at 37 [deg]C before RT-PCR, gave a negative result, which is to say that no amplicon was detected after the reaction was completed. This antecedent to the RT-PCR method may be applicable to other types of viruses, to viruses inactivated in other ways and to other molecular methods of virus detection.

Nunan, L. M. and D. V. Lightner (1997). "Development of a non-radioactive gene probe by PCR for detection of white spot syndrome virus (WSSV)." Journal of Virological Methods **63**(1-2): 193.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-1G/2/fcb9d76a3619ac6449cbbb965963b13b>

Combining primers created from the sequence information of two baculo-like viruses of penaeid shrimp, Baculovirus penaei (BP) and Monodon baculovirus (MBV), produced a 750 bp band on a 0.8% agarose gel using White Spot Syndrome Virus (WSSV), from *Penaeus monodon*, as the DNA template. The PCR fragment was ligated to a plasmid vector, (pGEM-T) and transformed, creating a 3.7 Kbp clone. The DNA insert was sequenced, and the original primer pair was located. Using restriction enzymes, the insert was isolated, excised and non-radioactively labeled. This cloned labeled fragment was tested by in situ hybridization for specificity and reactivity with BP, MBV and WSSV-infected shrimp tissues. The major advantage of this novel method of gene probe development is that no DNA sequence information of the targeted infectious agent needed to be known or available. In addition, tedious viral isolation and purification was circumvented. In this study, knowledge of the possible viral strain was important in limiting the PCR primer pairs investigated. The use of arbitrary primers designed for PCR assays from two other possibly related shrimp viruses, increased the likelihood that a generated PCR product would be specific for WSSV.

Nystrom, K., M. Biller, et al. (2004). "Real time PCR for monitoring regulation of host gene expression in herpes simplex virus type 1-infected human diploid cells." *Journal of Virological Methods* **118**(2): 83.

<http://www.sciencedirect.com/science/article/B6T96-4BVP8FY-1/2/ecdaff1c9d755a984c63b7f183a5585f>

Herpes simplex virus type 1 (HSV-1) induces prominent shifts in the rates of transcription of host cellular genes of relevance for the outcome of the viral infection. The quantitative analysis of transcription may be obscured by virus-induced alterations in the levels of RNA encoded by cellular housekeeping genes that are used commonly for normalisation of real time reverse transcription PCR (RT-qPCR). In the present study, we analysed [beta]-actin, GAPDH and 18S rRNA for their usefulness in normalisation of RT-qPCR analysis of the transcription of the HSV-1 gamma gB-1 gene and FUT5, a cellular gene induced by viral infection. The transcription of these genes was monitored in a TaqMan-based real time RT-PCR system over a 24 h interval of virus infection of human embryonic lung fibroblasts. The levels of gB-1 and FUT5 RNA were normalised via difference in the threshold cycle ([Delta]Ct) values relative to each and one of the housekeeping genes or calculated in relation to the number of infected cells without any further normalisation. The levels of RNA encoded by [beta]-actin or GAPDH were found to vary by several orders of magnitude during HSV-1 infection, introducing large errors in the estimation of the gB-1 and FUT5 RNA levels. In contrast, the variation of Ct values for 18S rRNA was less than one cycle during 24 h period of HSV-1 infection. The FUT5 and gB-1 RNA figures obtained by [Delta]Ct normalisation relative 18S rRNA were identical to those calculated in relation to the number of infected cells. These data recommend 18S rRNA for normalisation in HSV-1-infected human cells but discourage the use of [beta]-actin and GAPDH RNA for this purpose. By applying these procedures, it was shown that the transcription of FUT5 was increased by 50-fold 5-24 h after HSV-1 infection and 200-fold by the inhibition of viral DNA replication in HSV-infected cells.

O'Shea, M. K. and P. A. Cane (2004). "Development of a highly sensitive semi-quantitative real-time PCR and molecular beacon probe assay for the detection of respiratory syncytial virus." *Journal of Virological Methods* **118**(2): 101.

<http://www.sciencedirect.com/science/article/B6T96-4BY42V3-1/2/72cdebe02966a90458710dc3c2a18c4c>

Molecular beacons are a novel class of oligonucleotide probe capable of reporting the accumulation of target amplicon during real-time PCR by the emission of a fluorescent signal. A novel assay for the detection and estimation of respiratory syncytial virus (RSV) nucleic acid in clinical specimens based on real-time PCR utilising such a probe was developed. The probe consisted of two short arm sequences and a central loop sequence complementary to a region of the N gene (the target amplicon). The probe was characterised and a semi-quantitative nested real-time PCR using a LightCycler instrument was optimised. Standard curves were generated using cycle threshold (Ct) values calculated from several assays over a range of logarithmic RSV titres. Linear coefficient correlations were close to one ($r^2=0.998$) and the detection limit of the optimised assay was reproducibly shown to be 1×10^{-4} pfu/ml. The intra-assay coefficient of variation (CV) of Ct values of the optimal assay was 0.8% and the CV of quantification data was 6.6%. The interassay CV of Ct values was 2.0% and the quantification CV was 6.7%. The validity of the assay for the detection of RSV in clinical specimens was assessed by analysing ten specimens previously assayed in a different laboratory. Real-time PCR analysis was completely consistent with the results of prior analysis. The rapidity, sensitivity and specificity of the assay should greatly facilitate epidemiological studies, particularly in adults as existing methods perform better on clinical specimens from children.

Okamoto, H., S. Kobata, et al. (1996). "A second-generation method of genotyping hepatitis C virus by the polymerase chain reaction with sense and antisense primers deduced from the core gene." Journal of Virological Methods **57**(1): 31.

<http://www.sciencedirect.com/science/article/B6T96-3VXJ8FF-4/2/4f83ebd4df7935cae0f18c24b6941bdb>

A second-generation method of genotyping hepatitis C virus (HCV) was developed by the polymerase chain reaction (PCR) with sense as well as antisense primers deduced from the core gene. HCV RNA specimens extracted from sera were reverse-transcribed and amplified with universal primers in the first round of PCR to obtain fragments of 433 base pairs representing nucleotides 319-751. In the second round of PCR, portions of PCR products were amplified separately with sense and antisense primers specific for each of the five common genotypes prevailing across the world i.e., I/1a, II/1b, III/2a, IV/2b and V/3a. The specificity of the method was verified by a panel of 177 HCV isolates of various genotypes in the genetic groups 1-9. It allowed clear differentiation of genotype I/1a from II/1b which was not always accomplished by the previous method. When 501 sera from blood donors and hepatitis patients with HCV viremia from various countries were genotyped by the second-generation method, 478 (95.4%) were classified into the five genotypes. HCV RNA samples from 23 (4.6%) sera were not classifiable into any of the five common genotypes and, by sequence analysis, 22 were found to be of four genotypes in group 4 and one of genotype 1c in Simmonds' classification.

Okuda, M. and K. Hanada (2001). "RT-PCR for detecting five distinct Tospovirus species using degenerate primers and dsRNA template." Journal of Virological Methods **96**(2): 149.

<http://www.sciencedirect.com/science/article/B6T96-43DDGXG-5/2/9f7f4a76d586d0086922e829e8a244b5>

RT-PCR procedures for detection of multiple species of tospovirus from plant tissues were investigated. Downstream primers were designated from the 3' untranslated sequences of the S RNA. An upstream primer was designated from the degenerated sequences of the nucleocapsid protein. Approximately 450 bp DNA fragments were detected when Tomato spotted wilt virus (TSWV)- or Impatiens necrotic spot virus (INSV)- infected tissues were examined. Approximately 350 bp DNA fragments were detected when Watermelon silver mottle virus (WSMoV)- or Melon

yellow spot virus (MYSV)-infected tissues were examined. Template RNA was extracted using CF 11 cellulose powder, and nonspecific amplification became unnoticeable when double-stranded RNA was used. The amplified fragments of WSMoV were differentiated from those of MYSV by AluI or TaqI digestion. The amplified fragments of TSWV were differentiated from those of INSV by DraI or HindIII digestion. An alstroemeria plant that was infected with an unidentified tospovirus was also examined, and a 350 bp fragment that was 97% identical to Iris yellow spot virus was detected. This method, therefore, detected at least five distinct Tospovirus species.

Olvera, A., M. Sibila, et al. (2004). "Comparison of porcine circovirus type 2 load in serum quantified by a real time PCR in postweaning multisystemic wasting syndrome and porcine dermatitis and nephropathy syndrome naturally affected pigs." Journal of Virological Methods **117**(1): 75.

<http://www.sciencedirect.com/science/article/B6T96-4BMK1TM-1/2/6aad5437203cfcf9072aff5468feebfa>

Postweaning multisystemic wasting syndrome (PMWS) diagnosis is based on the presence of characteristic histopathological lymphoid lesions and porcine circovirus type 2 (PCV2) within these lesions. Previous studies indicate that PCV2 load is higher in PMWS affected than in PCV2 infected, healthy pigs. On the other hand, PCV2 has been suggested to play a role in porcine dermatitis and nephropathy syndrome (PDNS) pathogenesis. This study describes a new TaqMan(c) real time PCR assay and its use to quantify viral load in serum samples. Serum viral loads were related with different degrees of PMWS characteristic lesions and PDNS cases. DNA extracted from serum samples from 75 animals with mild, moderate and severe PMWS lesions and 12 animals with PDNS was used as template. PCV2 DNA was quantified in 69 of 75 PMWS cases and in 11 of 12 PDNS cases. Significant differences in PCV2 load were observed between animals with severe, moderate and mild PMWS lesions, although variability within each group was high, probably due to heterogeneity in disease progression. These results suggest that high viral load is a major feature of PMWS affected pigs. PDNS affected animals had lower PCV2 loads. No significant differences in viral load were found between animals suffering from PDNS and animals with mild PMWS characteristic lesions, which were unaffected clinically.

Oviedo, J. M., F. Rodriguez, et al. (1997). "High level expression of the major antigenic African swine fever virus proteins p54 and p30 in baculovirus and their potential use as diagnostic reagents." Journal of Virological Methods **64**(1): 27.

<http://www.sciencedirect.com/science/article/B6T96-3RHM7T6-1X/2/7af5f3d9c9d003c6323ebe27c7e37be9>

At present, the eradication of African swine fever (ASF) in affected countries is based only on an efficient diagnosis program because of the absence of an available vaccine. The highly antigenic ASF virus proteins p54 and p30, encoded by genes E183L and CP204L respectively, were expressed in baculovirus for diagnostic purposes. A sequence comparison analysis of these genes from different field virus strains which are geographically diverse and isolated in different years, revealed that both genes are completely conserved among the isolates. Partially purified baculovirus-expressed proteins were used in ELISA and Western blot for ASF antibody detection in sera from experimentally inoculated pigs and field sera from ASF innaparent carriers. These comparative analyses showed that p54 presents better reactivity than p30 in Western blot. However, recombinant p30 was more efficient for antibody detection by ELISA, improving the discrimination between positive and negative sera by this technique. These data suggest the convenience of using p30 as ELISA antigen, while p54 should be the selected antigen for ASF virus antibody detection by Western blot. The combined use of both antigens for serodiagnosis of ASF disease will improve the sensitivity of innaparent carriers detection, facilitating also the

interpretation of the tests, and eliminating the use of ASF virus in antigen production.

Paragas, J. and J. A. Blaho (1998). "Cosolvents facilitate DNA synthesis in the herpes simplex virus 1 unique short (Us) inverted repeat." Journal of Virological Methods **73**(1): 53.

<http://www.sciencedirect.com/science/article/B6T96-3T2PCND-6/2/250e8b0381b3b0894cc9aac7c4a6a214>

DNA synthesis under standard conditions is not successful within a portion of the Us1 gene of HSV-1 which is juxtaposed to an 86% G+C-containing tract in the Us inverted repeat sequence. We report that the independent addition of specific amounts of at least three different types of cosolvents is capable of facilitating DNA synthesis within this G+C-rich region. In addition, this strategy was used to successfully place a specific site-directed mutation in the Us1 gene. Consideration of these observations should enable future site-specific mutational analyses of portions of the HSV-1 genome which have traditionally been unamenable to genetic manipulations.

Parshionikar, S. U., J. Cashdollar, et al. (2004). "Development of homologous viral internal controls for use in RT-PCR assays of waterborne enteric viruses." Journal of Virological Methods **121**(1): 39.

<http://www.sciencedirect.com/science/article/B6T96-4CVR4D3-1/2/9bd36ffdfc5ee6c642d648e20707746>

Enteric viruses often contaminate water sources causing frequent outbreaks of gastroenteritis. Reverse transcription-polymerase chain reaction (RT-PCR) assays are commonly used for detection of human enteric viruses in environmental and drinking water samples. RT-PCR provides a means to rapidly detect low levels of these viruses, but it is sensitive to inhibitors that are present in water samples. Inhibitors of RT-PCR are concentrated along with viruses during sample processing. While procedures have been developed to remove inhibitors, none of them completely remove all inhibitors from all types of water matrices. This problem requires that adequate controls be used to distinguish true from potentially false-negative results. To address this problem, we have developed homologous viral internal controls for hepatitis A virus (HAV), poliovirus, Norwalk virus and rotavirus. These internal controls can be used in RT-PCR assays for the detection of the above viruses by competitive amplification, thereby allowing the detection of false negatives in processed water samples. The internal controls developed in this study were successfully tested with virus-seeded environmental water sample concentrates.

Pasquier, C., N. Millot, et al. (2001). "HIV-1 subtyping using phylogenetic analysis of pol gene sequences." Journal of Virological Methods **94**(1-2): 45.

<http://www.sciencedirect.com/science/article/B6T96-42Y12XF-6/2/d80f24b7001e51dc6faacfbf8b23f572>

HIV-1 pol gene sequencing is now used routinely in France to identify mutations associated with resistance to reverse transcriptase (RT) or protease (PR) inhibitors. These sequences may also provide other information, such as the HIV-1 subtype. HIV-1 subtyping was compared using the RT and PR gene sequences to heteroduplex mobility assay (HMA) of the envelope gene. The RT and PR genes of 51 samples that had been subtyped earlier by HMA were sequenced. Sequences were aligned and subtypes were determined by phylogenetic analysis with reference

HIV sequences. HMA gave the following subtypes: A (20), B (19), C (1), D (3), F (1), G (3) and CRF01-AE (4). Phylogenetic analysis of the RT gene gave: A (5), B (19), C (2), D (3), F (1), G (6), J (2), CRF01_AE (4), CRF02_AG (7) and undetermined (2). PR gene analysis did not infer subtypes with sufficient confidence. HMA and RT subtyping was not in agreement in nine cases. RT subtyping can identify CRF02_AG and CRF01_AE variants from A subtype RT. It was shown that phylogenetic analysis of the RT gene could provide a useful method for HIV-1 subtyping. The length of the amplicon and the relative performance of each primer pair used in this study favoured RT sequences as a subtyping tool. One potential advantage over env subtyping HMA is the ability to identify some circulating recombinant forms (CRFs).

Petrik, J., G. J. M. Pearson, et al. (1997). "High throughput PCR detection of HCV based on semiautomated multisample RNA capture." Journal of Virological Methods **64**(2): 147.

<http://www.sciencedirect.com/science/article/B6T96-3RJ9BMF-5/2/9cff2ed2ded22d32025f3dcb5ae1436b>

An amplification procedure based on a semiautomated 60-sample RNA capture, including combined reverse transcription/polymerase chain reaction (RT-PCR) and nested PCR/Tagman amplicon detection, is described. It can be completed within a working day and is suitable for the development of a fully automated system. HCV RNA-specific capture is independent of the sequence variations as it targets the poly(U) tract commonly present at the 3'-end of the HCV genome (U-capture). The type specificity of the assay determined in a panel of 56 confirmed HCV antibody-positive samples (genotypes 1-6) was slightly better when compared to a commercial assay. The sensitivity evaluated on serial dilutions of representative samples was equal for genotypes 1, 2, 5, 6, or increased for genotypes 3 and 4 with the U-capture assay.

Poon, H., E. Jimenez, et al. (1993). "Detection of bovine leukemia virus RNA in serum using the polymerase chain reaction." Journal of Virological Methods **41**(1): 101.

<http://www.sciencedirect.com/science/article/B6T96-476RMYJ-6K/2/5fef2abb18e0a655d107030563c44935>

A method was developed for detecting bovine leukemia virus (BLV) RNA in serum samples using a pair of primers from the BLV polymerase gene in the polymerase chain reaction (PCR). The PCR was able to detect 3800-7600 molecules of BLV RNA. At this level of sensitivity eleven pools of adult and one fetal bovine serum appeared free from BLV contamination.

Pratelli, A., V. Martella, et al. (2001). "Genomic characterization of pestiviruses isolated from lambs and kids in southern Italy." Journal of Virological Methods **94**(1-2): 81.

<http://www.sciencedirect.com/science/article/B6T96-42Y12XF-9/2/65624063a12db9b5ada050304765320d>

A nested polymerase chain reaction was used to identify 13 pestivirus strains isolated from small ruminants in several mixed (sheep and goats) flocks of Southern Italy, and for classification as bovine viral diarrhoea virus (BVDV) type 1, BVDV type 2, and Border disease virus (BDV) genotypes. Of the nine ovine isolates, two were characterized as BVDV type 1, and seven as BVDV type 2. The four pestiviruses isolated from kids belong to BVDV type 1. None of the pestivirus strains tested could be classified as 'true' BDV (genotype 3). Although BVDV type 2

has been described in Europe rarely, the characterization of BD/90-1M strain as BVDV type 2, isolated in Italy in 1990, demonstrates that this genotype has been circulating in Italy since the 1990s.

Pratelli, A., V. Martella, et al. (2003). "Genetic diversity of a canine coronavirus detected in pups with diarrhoea in Italy." Journal of Virological Methods **110**(1): 9.

<http://www.sciencedirect.com/science/article/B6T96-488G8YB-1/2/97c330073d15a9fb1cf3545d25dd2edf>

The sequence of the S gene of a field canine coronavirus (CCoV), strain Elmo/02, revealed low nucleotide (61%) and amino acid (54%) identity to reference CCoV strains. The highest correlation (77% nt and 81.7% aa) was found with feline coronavirus type I. A PCR assay for the S gene of strain Elmo/02 detected analogous CCoVs of different geographic origin, all which exhibited at least 92-96% nucleotide identity to each other and to strain Elmo/02. The evident genetic divergence between the reference CCoV strains and the newly identified Elmo/02-like CCoVs strongly suggests that a novel genotype of CCoV is widespread in the dog population.

Pratelli, A., V. Martella, et al. (2003). "Identification of coronaviruses in dogs that segregate separately from the canine coronavirus genotype." Journal of Virological Methods **107**(2): 213.

<http://www.sciencedirect.com/science/article/B6T96-47DTDTF-N/2/66948c55e9362947f2496c0e4bc5eafd>

The genetic diversity of 16 canine coronavirus (CCoV) samples is described. Samples were obtained from pups infected naturally living in different areas. Sequence data were obtained from the M gene and pol1a and pol1b regions. The phylogenetic relationships among these sequences and sequences published previously were determined. The canine samples segregated in two separate clusters. Samples of the first cluster were intermingled with reference strains of CCoV genotype and therefore could be assigned to this genotype. The second cluster segregated separately from CCoV and feline coronavirus genotypes and therefore these samples may represent genetic outliers. The reliability of the classification results was confirmed by repeating the phylogenetic analysis with nucleotide and amino acid sequences from multiple genomic regions.

Pratelli, A., M. Tempesta, et al. (1999). "Development of a nested PCR assay for the detection of canine coronavirus." Journal of Virological Methods **80**(1): 11.

<http://www.sciencedirect.com/science/article/B6T96-3WM5CT3-2/2/d5d4acb70659bd6b1089e8b5c3c06679>

A diagnostic test for canine coronavirus (CCV) infection based on a nested polymerase chain reaction (n-PCR) assay was developed and tested using the following coronavirus strains: CCV (USDA strain), CCV (45/93, field strain), feline infectious peritonitis virus (FIPV, field strain), transmissible gastroenteritis virus (TGEV, Purdue strain), bovine coronavirus (BCV, 9WBL-77 strain), infectious bronchitis virus (IBV, M-41 strain) and fecal samples of dogs with CCV enteritis. A 230-bp segment of the gene encoding for transmembrane protein M of CCV is the target sequence of the primer. The test described in the present study was able to amplify both CCV and TGEV strains and also gave positive results on fecal samples from CCV infected dogs. n-

PCR has a sensitivity as high as isolation on cell cultures, and can therefore be used for the diagnosis of CCoV infection in dogs.

Pratelli, A., A. Tinelli, et al. (2002). "PCR assay for the detection and the identification of atypical canine coronavirus in dogs." Journal of Virological Methods **106**(2): 209.

<http://www.sciencedirect.com/science/article/B6T96-46WSX8S-6/2/dbd1d38351561ef0cb23980d01cd8c23>

Comparative sequence analysis of the PCR products of the M gene and fragments of the pol1a and pol1b genes of canine coronavirus (CCoV) have demonstrated that two separate clusters of CCoV are present in dogs. This note describes a PCR assay to identify atypical CCoV strains with nucleotide substitutions in the M gene. A total of 177 faecal samples from dogs CCoV positive previously with the PCR assay were analysed. Sixty-two of the 177 samples were amplified with the PCR described in the present study and were thus considered atypical CCoVs. The specificity of the PCR typing assay was confirmed by sequence analysis of the PCR products.

Puig, M., S. Pina, et al. (2000). "Description of a DNA amplification procedure for the detection of bacteriophages of *Bacteroides fragilis* HSP40 in environmental samples." Journal of Virological Methods **89**(1-2): 159.

<http://www.sciencedirect.com/science/article/B6T96-429RNYH-J/2/0a8d63b24e9477e01fb6c69bcd067de4>

A molecular test based on DNA amplification by PCR was developed for the detection of bacteriophages of *Bacteroides fragilis* strain HSP40 in the environment. These specific phages are associated with faecal contamination of human origin. A homologous DNA region of 1.5 kb, identified previously by hybridisation, was used to design primers for the detection of *B. fragilis* HSP40 phages. A nested-PCR procedure for the DNA amplification of those phages was developed. The sensitivity of the nested-PCR was between 10⁻¹ and 10⁻² PFU for purified HSP40 phage solutions, sewage and seawater samples, and between 1 and 10 PFU for river water samples. Specific amplification of HSP40 phages was observed when viral suspensions of 103 PFU/ml or lower were used. Common levels of *B. fragilis* phages found in sewage are 101-102 PFU/ml. A total of 24 water samples (sewage, river water and seawater) were tested both by PCR and by plaque assay, to evaluate the efficiency of the molecular method in field samples. The data obtained by PCR in environmental samples showed good concordance with the PFU counts and a higher sensitivity.

Quan, C. M., M. Krajden, et al. (1993). "High-performance liquid chromatography to assess the effect of serum storage conditions on the detection of hepatitis C virus by the polymerase chain reaction." Journal of Virological Methods **43**(3): 299.

<http://www.sciencedirect.com/science/article/B6T96-476RMR1-59/2/839f0ee3725ce81e60bbf457cd804527>

The effect of various serum storage conditions on the detection of hepatitis C virus (HCV) by the polymerase chain reaction (PCR) was assessed. 50 [μl] aliquots of serum from four HCV PCR positive patients were subjected, in triplicate, to: (a) storage at -20[deg]C for 1, 5, 10 days; (b)

storage at room temperature (RT) for 1, 2, 7 days; (c) 1, 3, 5, and 10 successive freeze-thaw cycles; (d) incubation at 37[deg]C, and 56[deg]C for 1, 3, 24 h; and (e) storage in guanidium-thiocyanate extraction buffer at RT, and 4[deg]C for 1, 5, 10 days. PCR products were detected by agarose gel electrophoresis (AGE) and quantitatively by high-performance liquid chromatography (HPLC). Only storage in extraction buffer at RT for 5-10 days and incubation at 56[deg]C for 24 h appeared to result in a loss of [ges]50% of detectable HCV PCR product. Up to 10 successive freeze-thaw cycles, storage at -20[deg]C for up to 10 days or at RT for up to 7 days, storage in extraction buffer at RT for 1 day or at 4[deg]C for up to 10 days, and incubation at 37[deg]C for up to 24 h resulted in minimal PCR signal loss. HPLC was a reproducible method of detecting and quantitating HCV PCR products, and was more sensitive than AGE.

Ray, R., P. J. Cooper, et al. (1996). "Direct in situ reverse transcriptase polymerase chain reaction for detection of measles virus." Journal of Virological Methods **60**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-3VYV029-1/2/5c11b5c2bcb450ea425e8689d6c9641>

New methods are described for combined intracellular reverse transcription (RT) and polymerase chain reaction (PCR) using single primer pairs, with direct incorporation of digoxigenin-11-dUTP into amplicants (direct in situ RT/PCR). Routinely used fixatives and minimal pre-treatments were employed. Target sequences of measles virus nucleocapsid (N) and phosphoprotein genes were detected within measles virus infected Vero cells, both in suspension and in formalin-fixed sections, that had been treated by in situ reverse transcription and 30 cycles of direct in situ PCR. Uninfected cells, omission of Taq polymerase, and irrelevant primers were used as controls. Distribution of measles virus within infected cells was determined by in situ hybridisation and immunocytochemistry for measles virus N gene and protein, respectively. Confirmation of amplification within sections was by gel electrophoresis, Southern blotting and sequencing of extracted amplicons. In the majority of cases, measles-infected cells exhibited intense cytoplasmic signal after direct in situ PCR; this was not seen in uninfected cells or infected cells reacted either with irrelevant primers or without Taq polymerase. Unfixed cells in suspension required nested reaction. Measles-specific in situ hybridisation and immunocytochemistry gave an identical signal distribution in sections. Nuclear artifact occurred in some sections and was unpredictable, although it was greatest either in areas of cellular damage, following DNase predigestion, or with vigorous protease pre-treatment. In situ RT-PCR is feasible for measles virus in acutely infected cells both in sections and in suspension. Further work is required to improve the procedure and to eliminate artefactual nuclear signal.

Reetoo, K. N., S. A. Osman, et al. (1999). "Development and evaluation of quantitative-competitive PCR for quantitation of coxsackievirus B3 RNA in experimentally infected murine tissues." Journal of Virological Methods **82**(2): 145.

<http://www.sciencedirect.com/science/article/B6T96-3XT0BN2-6/2/603d7118f2bb100f7c234314488bba18>

A method is described for quantitation of enterovirus RNA in experimentally infected murine tissues. Viral RNA was extracted from tissue samples and amplified by reverse transcriptase PCR in the presence of an internal standard RNA. The ratio of PCR product derived from viral RNA and internal standard RNA was then determined using specific probes in a post-PCR electrochemiluminescent hybridization assay. This provided an estimate of the viral RNA copy number in the original sample, and detection of PCR product derived from internal standard RNA validated sample processing and amplification procedures. RNA copy number correlated with viral infectivity of cell culture-derived virus, and one tissue culture infective dose was found to

contain approximately 103 genome equivalents. The ratio of RNA copy number to infectivity in myocardial tissue taken from mice during the acute phase of coxsackievirus B3 myocarditis was more variable ranging from 104-107, and was dependent on the stage of infection, reflecting differential rates of clearance for viral RNA and viral infectivity. The assay is rapid, and could facilitate investigations which currently rely upon enterovirus quantitation by titration in cell culture. This would be useful for experimental studies of viral pathogenesis, prophylaxis and antiviral therapy.

Revilla-Fernandez, S., B. Wallner, et al. "The use of endogenous and exogenous reference RNAs for qualitative and quantitative detection of PRRSV in porcine semen." Journal of Virological Methods **In Press, Corrected Proof** <http://www.sciencedirect.com/science/article/B6T96-4FJGW2B-3/2/4b6e018f1b0d1f46b449b1acfc7a000f>

Semen is known to be a route of porcine reproductive and respiratory syndrome virus (PRRSV) transmission. A method was developed for qualitative and quantitative detection of the seminal cell-associated PRRSV RNA in relation to endogenous and exogenous reference RNAs. As endogenous control for one-step real-time reverse transcription (RT)-PCR UBE2D2 mRNA was selected. Particularly for the analysis of persistent infections associated with low copy numbers of PRRSV RNA, UBE2D2 mRNA is an ideal control due to its low expression in seminal cells and its detection in all samples analysed (n = 36). However, the amount of UBE2D2 mRNA in porcine semen varied (up to 106-fold), thus its use is limited to qualitative detection of PRRSV RNA. For quantitation, a synthetic, non-metazoan RNA was added to the RNA isolation reaction at an exact copy number. The photosynthesis gene ribulose-1,5-bisphosphate carboxylase/oxygenase large subunit (rbcl) from *Arabidopsis thaliana* was used as an exogenous spike. Unexpectedly, PRRSV RNA was detected in a herd of specific pathogen-free (SPF) boars which were tested ELISA-negative for anti-PRRSV antibodies. Therefore, RT-PCR for seminal cell-associated PRRSV is a powerful tool for managing the SPF status during quarantine programs and for routine outbreak investigations.

Rijsewijk, F., S. Pritz-Verschuren, et al. (2005). "Development of a polymerase chain reaction for the detection of Anguillid herpesvirus DNA in eels based on the herpesvirus DNA polymerase gene." Journal of Virological Methods **124**(1-2): 87.

<http://www.sciencedirect.com/science/article/B6T96-4F1503P-2/2/9df0f56d5ef0c68078e3d12a1633c505>

Anguillid herpesvirus (AnHV, also known as Herpesvirus anguillae or HVA) is found in both Japanese and European eels. Based on restriction enzyme analysis a small number of differences were found between AnHV isolated from Japanese eels and from European eels. The total genome size of both is about 245 kb, which is confirmed by alternating-field electrophoresis. Using a set of degenerate primers based on conserved regions within DNA-directed DNA polymerase coding regions, a 463 base pair fragment was isolated from both Japanese and European AnHV. Nucleotide sequence analysis showed that the cloned regions of both viruses have identical sequences. Based on this part of the DNA-polymerase sequence, primers were selected and used to develop a sensitive PCR to detect AnHV DNA in eel tissue samples. To avoid false negative results and to estimate the number of AnHV genome copies found in tissues, 100 copies of an internal control plasmid were added to the tissue samples. This semi-quantitative AnHV PCR can be used for both the European and Japanese isolates of AnHV, detects as few as 10 genome copies and is 100 times more sensitive than standard virus isolation.

Rimstad, E. and K. Ueland (1992). "Detection of feline immunodeficiency virus by a nested polymerase chain reaction." Journal of Virological Methods **36**(3): 239.

<http://www.sciencedirect.com/science/article/B6T96-476RM6B-1S/2/1fd9de23b89049a52b4dc338f65dfe2b>

A specific and sensitive polymerase chain reaction (PCR) procedure for the detection of feline immunodeficiency virus (FIV) in peripheral blood mononuclear cells (PBMC) was developed. PBMC from both blood samples and cultures were digested by proteinase K in a lysis buffer, and after heat inactivation of the proteinase, the resultant material was used in a two step amplification protocol using nested sets of primers. Two independent amplifications, from the gag and pol genes respectively, were performed in each tube. The PCR was positive for six of 14 samples from FIV seropositive adult cats, while all 36 samples from seronegative cats were negative. In comparison with an antigen-capturing ELISA procedure, the PCR detected FIV infection in PBMC cultures on average two days earlier.

Roberts, C. A., R. G. Dietzgen, et al. (2000). "Real-time RT-PCR fluorescent detection of tomato spotted wilt virus." Journal of Virological Methods **88**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-40TY33T-1/2/d294efce2cdf87866a0c40d592f87db1>

A real-time reverse transcription-polymerase chain reaction assay based on TaqMan(TM) chemistry was developed for the detection and quantification of tomato spotted wilt virus (TSWV). This method enabled sensitive, reproducible and specific detection of TSWV in 'leaf soak' and total RNA extracts from infected plants. TaqMan reliably detected TSWV in as little as 500 fg total RNA. The assay was 10-fold more sensitive than visualisation of ethidium bromide-stained bands following agarose gel electrophoresis. TSWV isolates from various crops and locations were detected with a cycle threshold of 20-26 in 1 ng total RNA extracted from fresh or freeze-dried leaves. A dilution series of in vitro transcripts from a cloned 628 base pair fragment of TSWV S RNA served as standard for quantification of viral template in infected leaf samples. The TaqMan assay detected reproducibly 1000 molecules of the target transcript.

Rohayem, J., S. Berger, et al. (2004). "A simple and rapid single-step multiplex RT-PCR to detect Norovirus, Astrovirus and Adenovirus in clinical stool samples." Journal of Virological Methods **118**(1): 49.

<http://www.sciencedirect.com/science/article/B6T96-4BT7JK6-1/2/c783ae5d862a1aa5da9d4aa1aa5ea7e1>

A single-step multiplex reverse transcription-polymerase chain reaction (RT-PCR) assay that detects and identifies Norovirus, Astrovirus and Adenovirus in clinical stool samples is described. Four hundred sixty stool samples were tested from patients with non-rotavirus acute gastroenteritis, that were either stored at -80 [deg]C and tested retrospectively, or tested immediately after viral nucleic acid extraction in a prospective manner, including outbreaks of gastroenteritis that occurred in Germany during the winter of 2003. The multiplex RT-PCR was validated against simplex RT-PCR with published primers for Norovirus (JV12/JV13 and p289/p290) and Astrovirus (Mon340/348), and against simplex PCR for Adenovirus. In both retrospective and prospective settings, the multiplex RT-PCR was equally sensitive and specific in detecting non-rotavirus infections compared with simplex RT-PCR/PCR. The specificity of the multiplex RT-PCR was assessed by sequencing of the amplicons that showed high nucleotide

identities to Norovirus genogroup I/1, I/4, II/2, or II/4 clades, as well as to Astrovirus serotypes 1, 2, 4, or 8. The multiplex RT-PCR was also more sensitive than Astrovirus and Norovirus antigen enzyme immunoassays (IDEIA, Dako), as well as Astrovirus isolation in cell culture. This novel multiplex RT-PCR is an attractive technique for the rapid, specific, and cost-effective laboratory diagnosis of non-rotavirus acute gastroenteritis.

Ros, C., M. E. Riquelme, et al. (1999). "Improved detection of five closely related ruminant alphaherpesviruses by specific amplification of viral genomic sequences." Journal of Virological Methods **83**(1-2): 55.

<http://www.sciencedirect.com/science/article/B6T96-3XVPG88-7/2/d5c0abe062eee652b1ff5ac334d67da2>

The detection and discrimination of five closely related ruminant alphaherpesviruses, bovine herpesvirus 1 (BHV-1), bovine herpesvirus 5 (BHV-5), caprine herpesvirus 1 (CapHV-1), cervine herpesvirus 1 (CerHV-1), and rangiferine herpesvirus 1 (RanHV-1), were achieved by the development of specific PCR systems. The highly variable N-terminal of the glycoprotein C was chosen to select the diagnostic primers, except for the CerHV-1 primers, which targeted the glycoprotein D region. All the assays proved specific since no heterologous virus was amplified. BHV-1 and BHV-5 were detected by using the same PCR assay and the different sizes of the amplification products allowed their identification on agarose gels. The practical diagnostic applicability of the novel PCR assays, with special regard to the BHV-1 system, has been evaluated on clinical samples from experimentally infected animals.

Sagazio, P., M. Tempesta, et al. (1998). "Antigenic characterization of canine parvovirus strains isolated in Italy." Journal of Virological Methods **73**(2): 197.

<http://www.sciencedirect.com/science/article/B6T96-3TGVK28-7/2/95394439de447d154ef4dd58b6eac5ee>

28 isolates of canine parvovirus type-2 (CPV-2) were obtained from dogs with hemorrhagic gastroenteritis in Italy. The antigenic structure of CPV-2 isolates was characterized, using four discriminating monoclonal antibodies. In addition, four vaccinal strains were examined. Similar to reports from Australia and the United Kingdom, a much higher prevalence of CPV-2a (25/28 isolates) was observed than the other variant type, CPV-2b (3/28 isolates). DNA fragments (2.2 kbp) of representative strains of CPV-2, CPV-2a and CPV-2b were amplified by the polymerase chain reaction (PCR) and the products were digested by the restriction enzymes (RE) RsaI, HpaII, HindIII and PvuII. The RsaI enzyme allows the differentiation of CPV-2 from CPV-2a and CPV-2b.

Saito, T., S. Matsumoto, et al. (1998). "Multicyclic reverse transcription-polymerase chain reaction assay system for quantitation of GB virus-C/hepatitis G virus RNA in serum." Journal of Virological Methods **74**(2): 185.

<http://www.sciencedirect.com/science/article/B6T96-3V5082S-7/2/99c3cccab7fe3b48c34d9ef79a26f4d5>

A new quantitative reverse transcription-polymerase chain reaction (RT-PCR) method is described for analyzing the amount of GB virus-C (GBV-C)/hepatitis G virus (HGV) RNA in

serum. This multicyclic RT-PCR (MRT-PCR) method used oligonucleotide primers deduced from the 3' noncoding region (3'NCR) that is highly conserved among GBV-C/HGV isolates. Quantitation of GBV-C/HGV RNA using MRT-PCR ranged between 102 and 1010 copies/ml when PCR cycle number was regulated at exponential amplification of the products. Competitive RT-PCR (CRT-PCR) was carried out with mutant RNA and sample that had been measured by MRT-PCR. Quantitation of GBV-C/HGV RNA using both methods agreed. MRT-PCR detected viral RNA in a single step PCR, and demonstrated a high degree of sensitivity that was equal to that of the RT-PCR procedure, which used nested primers deduced from the non-structural (NS) 3 region. The MRT-PCR method for quantitation of GBV-C/HGV RNA in serum may prove useful for diagnosis.

Saito, T., Y. Munakata, et al. (2003). "Evaluation of anti-parvovirus B19 activity in sera by assay using quantitative polymerase chain reaction." Journal of Virological Methods **107**(1): 81.

<http://www.sciencedirect.com/science/article/B6T96-46YXPVK-6/2/6624b5ec4f802415c0141af6f7bcd2b>

Human parvovirus B19 (B19) infects cells of erythroid lineage. Production of neutralizing antibodies (Abs) is indispensable for recovery from B19-related disease state. In this study, we used a convenient method to measure neutralizing activities in human sera by using a real-time quantitative PCR based assay. Erythroid cell line KU812Ep6 was incubated with test sera before infection with B19 virus. The copy number of B19-DNA in cultures was decreased in the presence of the sera from patients who recovered from acute B19 infection, whereas no decrease in B19-DNA was in cultures incubated with sera from healthy volunteers who had no B19 infection. The decrease in B19-DNA copy number was calculated and the inhibition percentage was expressed as neutralizing activity to B19. A clinical study showed that the levels of neutralizing ability were high in patients who recovered soon after acute B19 infection, but were low in some patients with a prolonged clinical course for recovery from B19 infection. This method is simple and convenient compared with methods described previously, showing its usefulness to evaluate the neutralizing activity to B19.

Saiz, M., S. Castro, et al. (1994). "Serotype-specific detection of bean common mosaic potyvirus in bean leaf and seed tissue by enzymatic amplification." Journal of Virological Methods **50**(1-3): 145.

<http://www.sciencedirect.com/science/article/B6T96-47DKYF8-H/2/87f59a02642bd2455bef08fc0ec16279>

An assay involving reverse transcription and polymerase chain reaction (PCR) is described for specific detection of serotypes A and B BCMV isolates in bean leaf and seed tissues. Three oligonucleotide primers designed according to the sequence data available allow, in appropriate combination, serotype-specific detection of BCMV. The sensitivity of the method was sufficient to detect BCMV in as little as 100 fg and 50 pg of infected leaf and seed tissues, respectively.

Sanchez-Seco, M. P., D. Rosario, et al. "Generic RT-nested-PCR for detection of flaviviruses using degenerated primers and internal control followed by sequencing for specific identification." Journal of Virological Methods **In Press, Corrected Proof**

<http://www.sciencedirect.com/science/article/B6T96-4FKYDM9-1/2/578f3dab73d77e4adfd7444b2f611d7a>

Flaviviruses are a widespread and numerous group of arboviruses that can cause serious illness in humans. The continuous and slow spread of certain flaviviruses, such as Dengue viruses, and the recent entry and spread of West Nile virus to the American continent, point to the need to control these infections. This control requires the use of suitable techniques for diagnostic and surveillance programmes. A generic RT-nested-PCR that is, theoretically, able to detect each member of the group has been designed. The identification of the detected virus is carried out by sequencing. The introduction of an internal control would reduce the number of false negative results and could be used to quantify the viral load in clinical samples where the method works well.

Sanchez-Seco, M. P., D. Rosario, et al. (2001). "A generic nested-RT-PCR followed by sequencing for detection and identification of members of the alphavirus genus." Journal of Virological Methods **95**(1-2): 153.

<http://www.sciencedirect.com/science/article/B6T96-433NRB5-H/2/3f2609203a01d4d108621be750cc519d>

A specific and sensitive nested RT-PCR method was developed for the detection of members of the alphavirus genus. Based on available sequences, degenerated primers were selected in the nsP4 gene. Reaction components and thermal cycling parameters were investigated and standardised, and optimal ones were selected. As few as 25 pfu/tube could be detected. The identities of the amplified fragments were confirmed by sequencing, and phylogenetic analysis was carried out. The resulting phylogenetic tree could be applied to classify every alphavirus according to its serogroup. This technique is suitable for rapid, sensitive and reliable detection of these viruses and may be very valuable for diagnostic applications and surveillance.

Saulnier, P., M. Vidaud, et al. (2003). "Development and validation of a real-time PCR assay for the detection and quantitation of p53 recombinant adenovirus in clinical samples from patients treated with Ad5CMV-p53 (INGN 201)." Journal of Virological Methods **114**(1): 55.

<http://www.sciencedirect.com/science/article/B6T96-49SNFD4-1/2/83c3e27a4029aea7fba1d9122574acf1>

The purpose of this study was to assess the usefulness of real-time PCR as a quantitative, highly reproducible, and sensitive method, for detecting and quantifying p53 recombinant adenovirus in biological samples from cancer patients receiving injections of Ad5CMV-p53. The dynamic range of this real-time PCR-based assay was wide (at least five orders of magnitude). Our assay used an internal positive control in the same PCR tube that is capable of detecting residual PCR inhibitors. Serial spiked samples in plasma with known quantities of Ad5CMV-p53 were evaluated. The minimum detection limit was 2 pfu per PCR (~50 pfu per ml of plasma) and the quantification values were reproducible. A total of 2069 controls tested with 1780 plasma samples from 286 patients enrolled in gene therapy trials using Ad5CMV-p53 were investigated. Using calibrators to adjust the quantitation value, the results confirmed the good performance of the assay. In conclusion, the high sensitivity, simplicity and reproducibility of the real-time Ad5CMV-p53 assay, allowing screening of large numbers of samples, combined with its wide dynamic range, make this method particularly suitable for monitoring gene therapy trials.

Sears, J. F. and A. S. Khan (2003). "Single-tube fluorescent product-enhanced reverse transcriptase assay with Ampliwax(TM) (STF-PERT) for retrovirus quantitation." Journal of Virological Methods

108(1): 139.

<http://www.sciencedirect.com/science/article/B6T96-47T8W17-4/2/d01195ea63d2951ed22610babe264af9>

A TaqMan fluorescent probe-based product enhanced reverse transcriptase (RT) assay is described in which the RT and polymerase chain reaction (PCR) steps are set-up in a single tube, in two compartments separated by Ampliwax(TM) (designated as single-tube fluorescent product-enhanced reverse transcriptase assay (STF-PERT)). This simplification of the two-step method resulted in increased assay reproducibility and handling efficiency while maintaining the sensitivity of the PERT assay (<10 virions). The STF-PERT assay can be used to quantitate low amounts of retrovirus in clinical and research materials and to evaluate retrovirus contamination in cell substrates and biological products in human use.

Shafer, R. W., A. Warford, et al. (2000). "Reproducibility of human immunodeficiency virus type 1 (HIV-1) protease and reverse transcriptase sequencing of plasma samples from heavily treated HIV-1-infected individuals." Journal of Virological Methods **86**(2): 143.

<http://www.sciencedirect.com/science/article/B6T96-403W2YC-5/2/211fd2658611ede185f47b60f768fccd>

The reproducibility of population-based human immunodeficiency virus type 1 (HIV-1) protease and reverse transcriptase (RT) sequencing was assessed using replicate aliquots of cryopreserved plasma samples obtained from seven heavily treated HIV-1-infected individuals. The sequence of each sample replicate was compared with the consensus sequence for that sample and 99.4% of 35128 amino acids were found to be concordant with the sample consensus. Partial discordances were present at 0.5% of positions and complete discordances were present at <0.1% of positions. To assess the reproducibility at detecting mutations (defined here as differences from the subtype B consensus sequence), the proportion of sequences having a mutation when at least two sequences from that sample had the same mutation were examined. There was a median of 13 protease and 18 RT mutations per sample for a total of 3126 mutations; 95% of these mutations were detected. However, sequencing of multiple clones from two samples demonstrated that those mutations present in a minority of clones were often not detected by population-based sequencing. These results suggest that HIV-1 protease and RT sequencing of circulating plasma virus is highly reproducible but that the sensitivity at detecting mutations may be low if those mutations are present as minor variants.

Shamloul, A. M., F. Faggioli, et al. (2002). "A novel multiplex RT-PCR probe capture hybridization (RT-PCR-ELISA) for simultaneous detection of six viroids in four genera: Apscaviroid, Hostuviroid, Pelamoviroid, and Pospiviroid." Journal of Virological Methods **105**(1): 115.

<http://www.sciencedirect.com/science/article/B6T96-46041YT-1/2/4e56918384176482201d2cdf6a26b133>

A rapid and sensitive assay was developed for the detection and identification of viroids by standard or multiplex reverse transcription-polymerase chain reaction (RT-PCR)-probe capture hybridization (RT-PCR-ELISA). The assay was applied successfully for the detection and identification of the following six viroid species from infected tissues: Potato spindle tuber viroid (Pospiviroid), Peach latent mosaic viroid (Pelamoviroid), Apple scar skin viroid (Apscaviroid), Apple dimple fruit viroid (Apscaviroid), Pear blister canker viroid (Apscaviroid), and Hop stunt viroid (Hostuviroid). Total RNA was obtained from infected tissue by the Qiagen RNeasy kit and,

then viroid cDNA was synthesized using viroid specific complementary DNA primer. To identify and differentiate the amplicons of the six viroids, each amplicon was digoxigenin (DIG)-labelled during the amplification process, and then detected by a colorimetric system using a biotinylated cDNA capture probe specific for each viroid. The results revealed that each capture probe hybridized only to its complementary DIG-labelled amplicon. Thus the six viroids can be detected and differentiated in a multiplex RT-PCR-ELISA assay. In the multiplex assay, cDNAs of six viroids were synthesized simultaneously in one tube, DIG-labelled during amplification, then a portion of the DIG-labelled amplified products was hybridized with selected capture probe. All the six viroid capture probes hybridized to their respective complementary DIG-labelled RT-PCR-amplified product. These findings are important for viroid detection and identification for studying host-viroid interactions and for management and control viroid diseases.

Shamloul, A. M. and A. Hadidi (1999). "Sensitive detection of potato spindle tuber and temperate fruit tree viroids by reverse transcription-polymerase chain reaction-probe capture hybridization." Journal of Virological Methods **80**(2): 145.

<http://www.sciencedirect.com/science/article/B6T96-3X29D70-5/2/e3613f2ae2220c4fea31c8809811e72f>

A rapid and sensitive assay for the specific detection of plant viroids using reverse transcription-polymerase chain reaction (RT-PCR) -probe capture hybridization (RT-PCR-enzyme-linked immunosorbent assay (ELISA)) was developed. The assay was applied successfully for the detection of potato spindle tuber viroid, peach latent mosaic viroid, or apple scar skin viroid from viroid infected leaf tissue. Clarified sap extract from infected leaf tissue was treated first with GeneReleaser(TM) polymeric matrix to remove inhibitors of RT-PCR reactions. Viroid cDNA was then synthesized and amplified using viroid specific primers in RT-PCR assays and the amplified viroid cDNA (amplicon) was digoxigenin (DIG) -labelled during the amplification process. The amplicon was then detected in a colorimetric hybridization system in a microtiter plate using a biotinylated cDNA capture probe. This system combines the specificity of molecular hybridization, the ease of the colorimetric protocol, and is at least 100-fold more sensitive than gel electrophoretic analysis in detecting the amplified product. Viroid cRNA may replace viroid cDNA as the capture probe. The cRNA probe was several fold more sensitive than the cDNA probe for viroid detection. Six to seven hours are needed to complete the RT-PCR-ELISA for viroid detection from infected leaf tissue.

Shin, J., E. M. Bautista, et al. (1998). "Quantitation of porcine reproductive and respiratory syndrome virus RNA in semen by single-tube reverse transcription-nested polymerase chain reaction." Journal of Virological Methods **72**(1): 67.

<http://www.sciencedirect.com/science/article/B6T96-3SXD XR-8/2/03cca086219a7ca36f7b08cbf32d7738>

Porcine reproductive and respiratory syndrome virus (PRRSV) is in boar semen for extended periods of time as determined by reverse transcription-nested polymerase chain reaction (RT-nPCR) assay. The concentration of PRRSV RNA in semen and the biological significance of the detection level, however, remain to be resolved. In order to determine the concentration of PRRSV VR-2332 (a prototypic strain of North American isolates) in semen following infection, we established a 'standard curve'-quantitative competitive (SC-QC)-RT-nPCR assay as well as an equimolar QC-RT-nPCR assay. A deletion-type competitor RNA derived from the Lelystad virus, a European strain of PRRSV, ORF-7 gene standard which shares the nested sets of primer recognition sequences with the VR-2332 ORF-7 gene was used as an internal standard. The equimolar QC-RT-nPCR assay results revealed that the number of copies of PRRSV RNA in 1

TCID₅₀/ml of virus derived from CL-2621 cell culture supernatants varied depending upon the type of samples in which virus was added; 143±24.0 and 266.5±48.5 copies in serum and semen samples spiked with PRRSV VR-2332, respectively. For the establishment of SC-QC-RT-nPCR assay, a standard curve was generated from band intensity ratios versus a series of known initial numbers of wild-type RNA copies which were quantified by the equimolar QC-RT-nPCR assay. Various initial numbers of copies of wild-type PRRSV RNA and each band intensity ratio with 1000 copies of competitor RNA were well correlated within the range of 100 to 200000 copies (R²=0.947). A 'standard curve' quantitation assay using competitive single-tube RT-nPCR will offer a rapid and reliable way to quantify low concentrations of PRRSV RNA in semen.

Singh, M. and R. P. Singh (1996). "Factors affecting detection of PVY in dormant tubers by reverse transcription polymerase chain reaction and nucleic acid spot hybridization." Journal of Virological Methods **60**(1): 47.

<http://www.sciencedirect.com/science/article/B6T96-3VYV029-5/2/30e07e74fe28d8beae6c23e901c5df2>

A reverse transcription polymerase chain reaction (RT-PCR) protocol was developed using two 20-mer primers located in nuclear inclusion genes NIa and NIb of potato virus Y (PVY). A 1017 bp PCR-product was detected in dormant potato tubers, infected with PVYO, but not in tubers from healthy plants. The PCR product was specific to PVY, as determined by Southern blot detection by hybridization with a PVYO-specific probe. As little as 1 pg of purified PVYO-RNA can be detected after RT-PCR amplification. The presence of phenolics or polysaccharides in tuber nucleic acids inhibited PVYO amplification, which was eliminated by diluting nucleic acid preparations prior to cDNA synthesis, modifying the nucleic acid extraction procedure by isopropanol precipitation and using phosphate-buffered saline-Tween in the cDNA mix. Potato cultivars differed in PVYO concentration in tubers as much as 128-fold. Tuber parts used for nucleic acid extractions were important in potato cultivars with low virus titres and combining of saps from bud and stem ends improved the PVYO detection. Storage of tubers up to 90 days at 4 [deg]C did not result in reduced detection of PVYO by both nucleic acid spot hybridization and RT-PCR, but RT-PCR band intensity was lower at longer storage periods. The primer pair developed in this study exhibited broad specificities with field isolates from Peru, Scotland and North America.

Singh, R. P. (1999). "A solvent-free, rapid and simple virus RNA-release method for potato leafroll virus detection in aphids and plants by reverse transcription polymerase chain reaction." Journal of Virological Methods **83**(1-2): 27.

<http://www.sciencedirect.com/science/article/B6T96-3XVPG88-4/2/977b58dd229d4b6f7912a88e1a7867d2>

A one-step, rapid and economical method for potato leafroll virus (PLRV) RNA release that is applicable to the use on a microcentrifuge scale is described. Discs (3-6 mm diameter) from leaves, petioles, stems, and tubers of potato plants were incubated in microcentrifuge tubes with detergent solution. The supernatants were used directly for reverse transcription (RT) and polymerase chain reaction (PCR). Of the seven nonionic detergents of the TritonX series evaluated, Triton X405R was the most effective, although X-405 and X-100R were also effective in releasing PLRV RNA. Application of the detergent method for detecting PLRV in greenhouse-grown potato organs (leaves, petioles, stems, tubers) and in field-grown tubers was demonstrated and compared to the multi-step phenol method. When individual aphids, *Myzus persicae*, were ground in 20 [μl] of detergent solution and supernatants were used for RT-PCR, virus was detected in single aphids in undiluted solutions and up to a dilution of 1:4. The concentration of

PLRV RNA released by the detergent method was substantially lower than that released by the phenol method. However, the detergent method was sensitive enough to detect PLRV from potato leaves, petioles, and stems 2 weeks after graft inoculation. The detergent method was rapid and economical, and has potential for large-scale application. The extracts survived over 37 days at room temperature, thus making it possible to mail extracts from remote areas lacking specialised RT-PCR facilities to a central laboratory for PLRV testing.

Singh, R. P., J. Kurz, et al. (1995). "Detection of potato leafroll virus in single aphids by the reverse transcription polymerase chain reaction and its potential epidemiological application." Journal of Virological Methods **55**(1): 133.

<http://www.sciencedirect.com/science/article/B6T96-3YYTF0W-1D/2/01e92bca3148bbe3d53dafaec5171d9c>

A reverse transcription and polymerase chain reaction (RT-PCR) system was developed using two 20-mer primers located in the potato leafroll virus (PLRV) capsid gene. A 336-bp PCR product was detected from aphids (*Myzus persicae*) which had been fed on PLRV-infected plants. The PCR band was specific to PLRV as determined by Southern blots and detection by a PLRV-specific probe. As little as 5 min exposure of aphids to PLRV-infected leaves resulted in the presence of PLRV-specific bands in 13% of aphids. However, the percentage of PLRV-positive aphids increased with longer exposure to infected sources and reached 90% after 3-4 days of feeding. PLRV can be detected from a single viruliferous aphid or a single viruliferous aphid combined with up to 29 non-viruliferous aphids. PLRV can be detected from freshly collected aphids, those stored at -70 [deg]C, or those stored in 70% ethanol at room temperature for extended periods. This method is applicable to assess the viruliferous nature of aphids caught in yellow-pan traps during the growing season or stored for over a year.

Singh, R. P., X. Nie, et al. (2000). "Duplex RT-PCR: reagent concentrations at reverse transcription stage affect the PCR performance." Journal of Virological Methods **86**(2): 121.

<http://www.sciencedirect.com/science/article/B6T96-403W2YC-3/2/c4001009ce2ed15163382fd0658efd00>

Test conditions for the simultaneous detection of potato leafroll virus (PLRV) and potato virus Y (PVY) in dormant tubers and leaves by reverse transcription-polymerase chain reaction (RT-PCR) were optimized. Various factors optimized at the reverse transcription (RT) stage rather than at the amplification (PCR) stage affected the outcome. In the simplex RT-PCR a onefold dNTPs concentration (0.5 mM) was sufficient in yielding a PLRV or PVY band. In contrast, the duplex RT-PCR required a minimum twofold dNTPs concentration (1.0 mM) during RT to produce distinct bands in PCR. Similarly, various proportions of antisense primers of PLRV and PVY used during RT affected subsequent duplex RT-PCR. Optimal amplification of both viruses were obtained at a ratio of 0.90:0.49 [mu]M of PLRV:PVY antisense primers. An interaction of dNTPs and RNA template concentration was observed. A higher concentration of RNA was required at onefold dNTPs concentration than at twofold dNTPs. Dilutions down to 1:300 of RNA template yielded distinct bands of both viruses at twofold dNTPs concentration. At optimized conditions of the duplex RT-PCR both viruses were reliably detected in composite samples at a ratio of one part infected sap mixed with 399 parts of sap from healthy tubers. Application of optimized conditions to singly- and doubly-infected tubers detected both viruses from naturally infected field-grown tubers. A nearly perfect correlation ($r^2=0.99$) was observed between visible plant symptoms and the virus detection from leaves and tubers by the duplex RT-PCR.

Singh, R. P., X. Nie, et al. (2002). "Sodium sulphite inhibition of potato and cherry polyphenolics in nucleic acid extraction for virus detection by RT-PCR." Journal of Virological Methods **99**(1-2): 123.

<http://www.sciencedirect.com/science/article/B6T96-448BG21-F/2/e2ba6de7b19d265c3bcb9cec6271bd11>

Phenolic compounds from plant tissues inhibit reverse transcription-polymerase chain reaction (RT-PCR). Multiple-step protocols using several additives to inhibit polyphenolic compounds during nucleic acid extraction are common, but time consuming and laborious. The current research highlights that the inclusion of 0.65 to 0.70% of sodium sulphite in the extraction buffer minimizes the pigmentation of nucleic acid extracts and improves the RT-PCR detection of Potato virus Y (PVY) and Potato leafroll virus (PLRV) in potato (*Solanum tuberosum*) tubers and Prune dwarf virus (PDV) and *Prunus* necrotic ringspot virus (PNRSV) in leaves and bark in the sweet cherry (*Prunus avium*) tree. Substituting sodium sulphite in the nucleic acid extraction buffer eliminated the use of proteinase K during extraction. Reagents phosphate buffered saline (PBS)-Tween 20 and polyvinylpyrrolidone (PVP) were also no longer required during RT or PCR phase. The resultant nucleic acid extracts were suitable for both duplex and multiplex RT-PCR. This simple and less expensive nucleic acid extraction protocol has proved very effective for potato cv. Russet Norkotah, which contains a high amount of polyphenolics. Comparing commercially available RNA extraction kits (Catrimox(TM) and RNeasy(TM)), the sodium sulphite based extraction protocol yielded two to three times higher amounts of RNA, while maintaining comparable virus detection by RT-PCR. The sodium sulphite based extraction protocol was equally effective in potato tubers, and in leaves and bark from the cherry tree.

Singh, R. P., M. Singh, et al. (1998). "Use of citric acid for neutralizing polymerase chain reaction inhibition by chlorogenic acid in potato extracts." Journal of Virological Methods **74**(2): 231.

<http://www.sciencedirect.com/science/article/B6T96-3V5082S-F/2/70fd6d5044a0673a2a80a8866266f339>

Polyphenolics are a widely distributed class of plant constituents implicated in the inhibition of the polymerase chain reaction (PCR). Since chlorogenic acid forms the bulk of phenolics in the potato tuber, a range of chlorogenic acid concentrations were tested for inhibition of reverse transcription (RT) and PCR steps. The RT step was inhibited at chlorogenic acid concentrations of 6.0 to 7.5 [μ g], while the PCR step was inhibited at much lower concentrations of 1.2 to 1.8 [μ g]. Incorporation of 1.2% citric acid at the nucleic acid extraction step prevented darkening of the extract and neutralized the inhibitory effect of chlorogenic acid.

Singh, S., V. T. K. Chow, et al. (2000). "RT-PCR, nucleotide, amino acid and phylogenetic analyses of enterovirus type 71 strains from Asia." Journal of Virological Methods **88**(2): 193.

<http://www.sciencedirect.com/science/article/B6T96-411PGRW-9/2/a1b8376344b1295742393fd5e48e326c>

A specific and sensitive method based on RT-PCR was developed to detect enterovirus 71 (EV71) from patients with hand, foot and mouth disease, myocarditis, aseptic meningitis and acute flaccid paralysis. RT-PCR primers from conserved parts of the VP1 capsid gene were designed on the basis of good correlation with sequences of EV71 strains. These primers successfully amplified 44 strains of EV71 including 34 strains isolated from Singapore in 1997

and 1998, eight strains from Malaysia isolated in 1997 and 1998, one Japanese strain and the neurovirulent strain EV71/7423/MS/87. RT-PCR of 30 strains of other enteroviruses including coxsackievirus A and B, and echoviruses failed to give any positive amplicons. Hence, RT-PCR with these primers showed 100% correlation with serotyping. Direct sequencing of the RT-PCR products of 20 EV71 strains revealed a distinct cluster with two major subgroups, thus enabling genetic typing of the viruses. The genetic heterogeneity of these strains culminated in amino acid substitutions within the VP1, VP2 and VP3 regions. The sequencing of a 2.9 kb fragment comprising the capsid region and the major part of 5' UTR of two Singapore strains revealed that they belonged to a group distinct from the prototype EV71/BrCr strain and the EV71/7423/MS/87 strain. The dendrogram generated from 341 bp fragments within the VP1 region revealed that the strains of Singapore, Malaysia and Taiwan belong to two entirely different EV71 genogroups, distinct from the three genogroups identified in another recent study.

Smith, G. R., R. Van de Velde, et al. (1992). "PCR amplification of a specific double-stranded RNA region of Fiji disease virus from diseased sugarcane." Journal of Virological Methods **39**(3): 237.

<http://www.sciencedirect.com/science/article/B6T96-476F61S-67/2/e61cf83990890fba99d5dcd116139156>

A 450-bp region from one species of the segmented dsRNA genome of Fiji disease virus (FDV) was amplified from total nucleic acid extracts of diseased plants by reverse transcription with MMLV, followed by amplification with Taq DNA polymerase (RT-PCR). Other FDV-specific regions (c 150 bp and c 270 bp) were also amplified from the dsRNA template. FDV cDNA was only synthesised when the viral dsRNA template was boiled and quenched with FDV-specific or random hexamer primers. The reverse transcriptase/DNA polymerase enzyme rTth appeared to yield only the 150 bp fragment from the dsRNA template under the conditions used. The level of sensitivity of RT-PCR for purified FDV dsRNA was 100 ag, approximately 104-fold more sensitive than detection with biotinylated DNA probe.

Smith, J., L. M. McElhinney, et al. (2000). "Assessment of template quality by the incorporation of an internal control into a RT-PCR for the detection of rabies and rabies-related viruses." Journal of Virological Methods **84**(2): 107.

<http://www.sciencedirect.com/science/article/B6T96-3YDG9HS-1/2/e00ff628ace2e3a0272d32f5b1bf6c98>

A method is described to assess RNA template quality by the incorporation of a ribosomal RNA (rRNA) internal (in tube) control into a standard rabies and rabies-related virus specific RT-PCR. Specific virus and rRNA templates were co-amplified in a duplex reaction from RNA extracts derived from 60 isolates representing all six of the established lyssavirus genotypes. To ensure a wide species applicability of this technique we demonstrated that the rRNA assay was capable of functioning using the cells or tissues of 14 different mammals. Parallel studies between the duplex and the unlinked lyssavirus assay demonstrated only a minor reduction in the sensitivity of the former test. The ribosomal and viral targets (unlike [beta]-actin RNA) were shown to have similar degradation kinetics making rRNA amplification a good control for viral target integrity. As a consequence, the use of this system would reduce the likelihood of obtaining false negative RT-PCR results from lyssavirus infected material.

Stamey, F. R., M. DeLeon-Carnes, et al. (2003). "Comparison of a microtiter plate system to Southern

blot for detection of human herpesvirus 8 DNA amplified from blood and saliva." Journal of Virological Methods **108**(2): 189.

<http://www.sciencedirect.com/science/article/B6T96-47PGC4N-6/2/68d06de6865414884ae2c743798ae715>

The recent discovery of human herpesvirus 8 (HHV-8) as the etiologic agent of Kaposi's sarcoma (KS) has led to the interest in the development of PCR for this virus that is accurate, rapid, and convenient. We developed a sensitive PCR assay for HHV-8 with microtiter plate detection of amplimers. DNA was purified from white blood cells and saliva from HIV-infected men with and without Kaposi's sarcoma and one-step PCR was undertaken with primer sets specific for the N-terminal region of the glycoprotein B gene and open reading frame (orf) 26 of HHV-8. PCR was performed on 40 clinical specimens, followed by Southern blot and microtiter plate detection of amplimers. Results from the two methods of detection were nearly identical. Sensitivity for both methods based on serial dilution of a known standard was five to ten copies of HHV-8 per 400 ng of cellular DNA. In conclusion, microtiter plate detection of HHV-8 PCR amplimers is as sensitive and specific as Southern blot with much faster turnaround time at comparable cost, and utilizes common laboratory equipment.

Stocher, M., V. Leb, et al. (2003). "A convenient approach to the generation of multiple internal control DNA for a panel of real-time PCR assays." Journal of Virological Methods **108**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-47PGC4N-4/2/ff45cc19f684bd3f3af8a09818fdd0b3>

Real-time polymerase chain reaction (PCR) assays allow convenient detection and quantitation of virus-derived nucleic acids in clinical specimens. When specimens are assayed for the presence of virus-derived nucleic acids against external standards, sample adequacy is not monitored. This can be achieved by using internal controls that are co-amplified with the virus-specific DNA in competitive PCR. Each of the various real-time PCR assays in a routine clinical laboratory requires its specific internal control. In order to complement a panel of virus-specific real-time PCR assays with internal controls, a convenient approach is described to generate the several internal controls within single DNA fragment. By applying composite primer technology, PCR primer sequences used in real-time PCR assays were added in 5' and 3' of a stretch of heterologous DNA during consecutive preparative PCRs. The heterologous DNA was used for internal control specific detection by e.g. FRET-hybridisation probes. The presented example of such a multiple internal control DNA contained five internal controls for five competitive LightCycler-PCR assays. All five PCR products derived from the multiple internal control DNA were detected with a single pair of specific FRET-hybridisation probes. The example described proved useful in real-time PCR assays specific for the detection of EBV-, CMV-, VZV- HSV-, and HBV-DNA on the LightCycler instrument. This methodology should enable laboratories to conveniently complement their panel of existing real-time PCR assays with a single multiple internal control DNA.

Strappe, P. M., T. H. Wang, et al. (1998). "In situ polymerase chain reaction amplification of HIV-1 DNA in brain tissue." Journal of Virological Methods **70**(2): 119.

<http://www.sciencedirect.com/science/article/B6T96-3SBVX4H-1/2/110f9577f665297b8bc637b2348039f5>

A direct in situ polymerase chain reaction (IS-PCR) assay is described for the detection of HIV-1

proviral DNA in formalin fixed paraffin embedded brain tissue. Biotin-16-dUTP is incorporated during the PCR process and microwave pretreatment of tissue sections ensures that no non-specific incorporation into damaged or nicked genomic DNA occurs. Two methods are compared to detect the biotinylated amplified product, the use of an avidin-biotin-alkaline phosphatase complex (ABC) and the application of tyramide signal amplification (TSA) which allows both chromogenic and fluorescence detection. TSA detection enhances the sensitivity of IS-PCR, permitting fewer PCR cycles and preserving tissue morphology.

Syrjanen, S., B. Andersson, et al. (1991). "The use of polymerase chain reaction in generation of biotinylated human papillomavirus DNA probes for in situ hybridization." Journal of Virological Methods **31**(2-3): 147.

<http://www.sciencedirect.com/science/article/B6T96-47DM18P-H/2/5a673ca2c3dc4bbb3f5895972b7eca0>

The polymerase chain reaction (PCR) was used to produce biotin-labelled human papillomavirus (HPV) 16- and 18-specific DNA probes for in situ hybridization (ISH). PCR was performed by using AmplitaqTM DNA amplification reagent kit according to the manufacturer's instructions, except that dTTP was substituted by different concentrations of biotinylated dUTP (bio-11-UTP). As template DNA, DNA extracted either from CaSki or HeLa cells was used. The reaction mixture was taken through up to 40 cycles of amplification in a Perkin-Elmer Cetus Thermal Cycler. The highest yield was achieved when the concentrations of dTTP and biotinylated dUTP were 150 and 50 μ M, respectively. ISH results compatible with those obtained with biotinylated whole genomic HPV DNA probes were demonstrated when primers from E7 and E6 ORF of the HPV-18 genome were used to produce the biotinylated probe by PCR. With HPV-16, several areas of the genome had to be amplified to generate a PCR probe with equal sensitivity as the whole genomic probe. The background staining was always stronger with the PCR probes than with the whole genomic probes. The sensitivity of the PCR probes does not seem to bear a clear-cut correlation with the size or nucleotide content of the probe, but it might rather depend on the three dimensional structure of the probe and the availability of biotin for the detection system by ISH.

Szemes, M., M. M. Klerks, et al. (2002). "Development of a multiplex AmpliDet RNA assay for simultaneous detection and typing of potato virus Y isolates." Journal of Virological Methods **100**(1-2): 83.

<http://www.sciencedirect.com/science/article/B6T96-44M1FHH-8/2/469ee9271f622a5bae98781123d31802>

A multiplex AmpliDet RNA assay was developed for the specific detection of potato virus Y (PVY), and for the differentiation of the PVYN, PVYO/C strains and the tuber necrotic isolates (PVYNTN). The assay is based on the generic amplification of a region within the coat protein coding region of all known PVY isolates by nucleic acid sequence-based amplification (NASBATM) and strain-specific detection by molecular beacons. PVYNTN-specific diagnosis is achieved by detecting PVYN and PVYO-specific sequences flanking a recombination site that is associated with the tuber necrotic pathotype. The assay exhibited good specificity toward the various PVY strains in both single and mixed infections. The technique was validated by the use of 47 PVY isolates originating from six countries. The results of the AmpliDet RNA assay were identical or consistent with those of biological characterisation in the decisive majority of cases.

Tai, J. H., M. S. Ewert, et al. (2003). "Development of a rapid method using nucleic acid sequence-based amplification for the detection of astrovirus." Journal of Virological Methods **110**(2): 119.

<http://www.sciencedirect.com/science/article/B6T96-48R3KGG-1/2/da81470d0bd99e7695e005ccec634d79>

We have developed a rapid method to detect astrovirus in fecal specimens utilizing nucleic acid sequence-based amplification (NASBA) and several detection methodologies, including a sandwich hybridization assay based on DNA-tagged liposomes (liposome-strip detection assay). RNA was extracted from 65 stool specimens that were positive for astrovirus by enzyme immunoassay and was amplified by both NASBA and reverse transcriptase PCR (RT-PCR). Also extracted and amplified were 19 specimens containing rotavirus, 20 specimens containing norovirus, five specimens containing adenovirus, 15 water negative control specimens, and eight specimens containing astrovirus reference strains. NASBA products were detected by electrochemiluminescence detection (ECL) and by liposome-strip detection; RT-PCR products were detected by ethidium bromide staining following gel electrophoresis and by liquid hybridization assay (LHA). There was no significant difference in the detection rates of NASBA- and RT-PCR-based assays, with one exception in which the NASBA/ECL assay detected astrovirus in eight specimens that tested negative by the RT-PCR/LHA assay. These results suggest that these NASBA-based detection methods have detection rates that are as good as or better than those of RT-PCR-based methods. Both NASBA and liposome-strip detection may be useful for field studies and environmental testing because these methods are rapid and do not require specialized equipment.

Tasca, S. I., R. J. Hoffman, et al. (1993). "Detection of Moloney murine sarcoma virus in tissues and cultured cells by the polymerase chain reaction." Journal of Virological Methods **41**(3): 255.

<http://www.sciencedirect.com/science/article/B6T96-476F65D-84/2/de74827c1b229f85cf7653d7be953ecb>

The polymerase chain reaction was used for Moloney murine sarcoma virus (MoMuSV) detection in frozen and formalin-fixed, paraffin-embedded tissue sections and cultured cells isolated from MoMuSV-induced tumors. Rapid DNA extraction by proteinase K digestion, followed by CHROMA SPIN + TE-100 column purification proved to be satisfactory. Two pairs of overlapping primers, flanking 1026 base pair (bp) to 221 bp, allowed to choose among four different length of DNA-amplified segments. Although net amplification was obtained for frozen tissue and tumor cultured cells in all combinations of primers, the maximum specificity and sensitivity resulted with 602 bp fragment. This product was fully and adequately digestible using Apa I and Sau3A I restriction endonucleases. DNA extracted from paraffinembedded sections yielded an amplification product only when the primer pair which delineated a 221-bp segment was used. This reproducible method could be useful for diagnostic and for pathogenetic investigations of MoMuSV infections.

Telenti, A., P. Imboden, et al. (1992). "Competitive polymerase chain reaction using an internal standard: Application to the quantitation of viral DNA." Journal of Virological Methods **39**(3): 259.

<http://www.sciencedirect.com/science/article/B6T96-476F61S-69/2/ecc5c7eaa4887b555bee09b652206856>

A general strategy for the construction of an internal standard for the polymerase chain reaction (PCR) is described together with its application in the evaluation of clinical samples. This internal

standard is a plasmid containing a modified target sequence that is co-amplified with the native target using the same set of primers. The co-amplification reaction will generate two fragments of different size that are readily separated without the need for restriction enzyme digestion. Thereafter, they are detected and quantitated by hybridization to the same probe. Detection of HIV proviral DNA was chosen as a model for this competitive PCR. The assay proved to be a sensitive tool for the detection of PCR inhibitors and allowed quantitation of HIV with a 20-30% variation coefficient. Despite limitations that appear inherent to the amplification process, internal standards appear to be useful tools for quantitative analysis by PCR.

Thomson, D. and G. Smith (1999). "Herpesvirus genome mapping: a rapid generic approach." Journal of Virological Methods **82**(1): 1.

<http://www.sciencedirect.com/science/article/B6T96-3XBV608-1/2/84aeedf0b4d0df6502118200de3091e8>

A protocol for mapping the genome of the alphaherpesvirus macropodid herpesvirus 1 is described. This protocol greatly simplifies a similar protocol that was used to map the genome of the poxvirus molluscum contagiosum virus. A single restriction digestion is carried out on the viral DNA, and the fragments cloned into a plasmid vector. The ends of each cloned fragment are sequenced, translated, and used to search peptide sequence databases. Putative genomic maps are constructed by assembling contiguous fragments identified by the sharing of common open reading frames and through the demonstrated colinearity of herpesvirus genomes belonging to the same subfamily. Oligonucleotide primers designed from the nucleotide sequence at the ends of each cloned fragment enable confirmation of putative contiguous fragments by PCR. Fragments not identified by searches of peptide databases are subcloned using a rapid subcloning method. This approach involves restriction digestion of the cloned fragment with restriction enzymes present in both the multiple cloning site of the vector, and within the fragment. Digested fragments larger than the vector are recircularised and transformed into bacteria to generate subclones for sequence analysis. This subcloning method can also be used to order rapidly genes within large clones.

Thomson, D. and G. Smith (2001). "PCR-based plasmid vector construction for generation of recombinant viruses." Journal of Virological Methods **94**(1-2): 7.

<http://www.sciencedirect.com/science/article/B6T96-42Y12XF-2/2/e09addc730d9a9b95ea8228568f29b40>

A totally polymerase chain reaction (PCR)-based protocol for construction of plasmids for production of recombinant macropodid herpesvirus 1 (MaHV-1) is described. This protocol greatly simplifies traditional methods that use restriction enzyme-based cloning or a combination of restriction enzyme cloning and the PCR. PCR is used to amplify the vector backbone containing an origin of replication and selectable marker, and the inserts to be cloned (5' and 3' viral homologous recombination regions and the reporter gene green fluorescent protein (GFP)). The inserts are cloned in a sequential manner with the intermediate vectors then amplified to produce the next vector. At its most basic, this involves, after the initial PCR amplification of vector and inserts, two additional PCR amplifications and three ligation events. This protocol is however totally generic, and can be used not only for construction of plasmids for production of recombinant viruses, but also for any general cloning applications.

Trottier, M., B. P. Schlitt, et al. (2002). "Enhanced detection of Theiler's virus RNA copy equivalents in the mouse central nervous system by real-time RT-PCR." Journal of Virological Methods **103**(1): 89.

<http://www.sciencedirect.com/science/article/B6T96-453NT2F-4/2/0b435e59016aaecd22d4db3a142d416b>

Infection of mice by low-neurovirulence Theiler's murine encephalomyelitis virus (TMEV), such as BeAn and DA viruses, provides a relevant experimental animal model for multiple sclerosis (MS). As a step toward determining the kinetics of a persistent central nervous system (CNS) infection that leads to chronic demyelination, we adapted a rapid, accurate and highly specific real-time reverse transcriptase-polymerase chain reaction (RT-PCR) assay for detection and quantitation of BeAn virus RNA copy equivalents in mouse tissues. The assay enabled detection of as few as 20-30 copies of BeAn virus RNA per [mu]g of total RNA from infected mouse tissues and results for spinal cord revealed the same high levels of BeAn RNA as detected by Northern hybridization during the first 4 months of the persistent infection, but also was able to detect virus RNA copies as late as 1 year post-infection. Real-time RT-PCR analysis of BeAn virus RNA copy equivalents in different parts of the CNS, analyses not possible by Northern hybridization, revealed the following cline of virus persistence: spinal cord>brainstem/cerebellum>cerebrospinal fluid (CSF)>cerebral hemispheres. Systemic organs, including heart, intestine and mesenteric lymph nodes of infected mice, showed no evidence of viral persistence at 4 months post-infection.

Tsuda, F., H. Okamoto, et al. (1999). "Determination of antibodies to TT virus (TTV) and application to blood donors and patients with post-transfusion non-A to G hepatitis in Japan." Journal of Virological Methods **77**(2): 199.

<http://www.sciencedirect.com/science/article/B6T96-3VR1B1H-9/2/e8194397a661b193f8b3f8313875d1a7>

Recently, a nonenveloped single-stranded DNA virus named TT virus (TTV) has been reported in association with non-A to G post-transfusion as well as sporadic acute and chronic liver disease. A method was developed for the detection of antibody to TTV (anti-TTV) by means of immune precipitation and detection of TTV DNA by the polymerase chain reaction. The test serum was incubated with TTV, recovered from feces of a carrier, and after incubation, the formed immune complexes were precipitated with goat antiserum to human IgG. TTV DNA was sought for by the polymerase chain reaction in both precipitate and supernatant. The detection of TTV DNA in the precipitate, but not in the supernatant, was considered to represent anti-TTV in the test serum. Of the 44 healthy blood donors in Japan, anti-TTV was detected in one of the six (17%) with TTV DNA and 11 of the 38 (29%) without TTV DNA. In the two patients with post-transfusion non-A to G hepatitis, free anti-TTV developed as they cleared TTV in serum. Anti-TTV complexed with TTV in serum, detectable by precipitating sera with goat anti-human IgG and testing for TTV DNA, elicited while the patients had elevated alanine transaminase levels. The determination of anti-TTV would be useful for detecting resolved infection in surveys for exposure to TTV in the general population, and for establishing the mechanism of liver injury associated with TTV infection.

Van Laethem, K., K. Beuselinck, et al. (1998). "Diagnosis of human immunodeficiency virus infection by a polymerase chain reaction assay evaluated in patients harbouring strains of diverse geographical origin." Journal of Virological Methods **70**(2): 153.

<http://www.sciencedirect.com/science/article/B6T96-3SBVX4H-4/2/a6e16bfe458047f13dfdf93acfaa1415>

Since the development of the highly sensitive polymerase chain reaction, PCR has been increasingly used for the diagnosis of viral infections, including the detection of human immunodeficiency virus (HIV), the causative agent of AIDS. In our laboratory a diagnostic PCR is carried out on proviral HIV-1 DNA using a standardised algorithm based on three HIV-1 primer sets. The three primer sets, amplifying a fragment in the LTR-gag gene, in the pol gene and in the env gene, are situated within conserved regions of the HIV-1 genome. These primers allow us to detect not only HIV strains from Belgian patients but also from African patients, who are, for historical reasons, a substantial part of the HIV-positive patients in Belgium. We are able to detect 1-5 copies of proviral HIV-1 DNA with each of the three nested primer sets. A sensitivity and specificity of 92 and 100%, respectively, were achieved when testing 24 Belgian and African HIV-1 seropositive samples. In our lab, the same PCRs are also used for the detection of viral RNA in cases of a doubtful undetectable viral load when using a commercial HIV-1 viral load assay. This is because present-day commercial assays are not entirely reliable with divergent strains. Both our 'in-house' diagnostic DNA and RNA-PCR can also be used semiquantitatively with limiting dilutions.

Vandamme, A.-M., S. Van Dooren, et al. (1995). "Detection of HIV-1 RNA in plasma and serum samples using the NASBA amplification system compared to RNA-PCR." Journal of Virological Methods **52**(1-2): 121.

<http://www.sciencedirect.com/science/article/B6T96-3YXC151-X/2/a3afbcd918ae8929dc7f40d7b7f89270>

The presence of HIV-1 RNA in the plasma and serum of European and African patients was monitored using RNA-polymerase chain reaction (RNA-PCR) and the new isothermal NASBA nucleic acid amplification system encompassing a gel-based detection assay (ELGA). Identical RNA extraction procedures, provided by the NASBA amplification system, were used for both methods. The detection limit for HIV-1 RNA, measured on a 10-fold dilution series of spiked HIVIIB in negative plasma, was about 0.05 CCID₅₀ per test for both methods. Both NASBA and RNA-PCR were more sensitive than a p24 assay for the detection of circulating HIV-1 virus in blood: 17 of the 34 (50%) p24 antigen-tested seropositives were p24-positive while 32 (94%) were positive by NASBA and 30 (88%) by RNA-PCR. Among the 45 seropositives, 34 of which were tested for p24 antigen, 43 (96%) were positive by NASBA and 41 (91%) by RNA-PCR. Almost all seropositives had a detectable viral load in 100 [µl] plasma. Lower viral loads were only encountered in some healthy seropositives with a higher CD4 count. There was no cross-reactivity with HIV-2 or HTLV-I with both the RNA-PCR and NASBA. The extraction method used permitted the detection of HIV-1 RNA equally well in serum and in plasma with heparin or EDTA.

Vanderhallen, H. and F. Koenen (1997). "Rapid diagnosis of encephalomyocarditis virus infections in pigs using a reverse transcription-polymerase chain reaction." Journal of Virological Methods **66**(1): 83.

<http://www.sciencedirect.com/science/article/B6T96-3RYCMYM-1D/2/85242a8bdd7275411681e02274e3e176>

Encephalomyocarditis virus (EMCV) is widespread and the economic losses caused by an EMCV outbreak in pig holdings and the similarity between a foot-and-mouth disease virus (FMDV) and an EMCV infection in young piglets stress the need for a rapid, specific and broad diagnostic assay. An alternative to the time-consuming seroneutralisation assay, currently used for the characterisation of EMCV, is described. An EMCV specific reverse transcription-polymerase chain reaction (RT-PCR), using primers located in a conserved region of the 3D gene of the viral genome, was developed and tested on 114 different EMCV isolates. The identity of the respective

amplicons was confirmed by sequencing. The potential of this assay for future diagnostic purposes was demonstrated by applying the RT-PCR on tissue samples collected from an experimentally infected piglet.

Venter, M., G. Napier, et al. (2000). "Cloning, sequencing and expression of the gene that encodes the major neutralisation-specific antigen of African horsesickness virus serotype 9." Journal of Virological Methods **86**(1): 41.

<http://www.sciencedirect.com/science/article/B6T96-3YS34HX-6/2/e135748986aec5916949874fdc8c4b72>

A marked improvement in the efficiency of cloning the large double stranded RNA (dsRNA) genome segments of African horsesickness virus (AHSV) was achieved when the dsRNA polyadenylation step was carried out with undenatured rather than strand-separated dsRNA. It is a prerequisite to use dsRNA of very high purity because in the presence of even trace amounts of single stranded RNA, the dsRNA appears to be poorly polyadenylated as judged by its effectiveness as a template for oligo-dT-primed cDNA synthesis. The full-length VP2 gene of AHSV-9, cloned by this approach, was sequenced and it was found to show the highest percentage identity (60%) to VP2 of AHSV-6, providing an explanation of why these two serotypes show some cross protection. The VP2 protein was also expressed in *Spodoptera frugiperda* (Sf9) cells by means of a baculovirus recombinant. The yield of the expressed VP2 was high, but the protein was found to be largely insoluble. Nine smaller, truncated VP2 peptides were subsequently expressed in insect cells, but no significant improvement in solubility of the peptides, as compared to that of the full-sized protein, was observed. A western immunoblot analysis of the overlapping peptides indicated the presence of a strong linear epitope located within a large hydrophilic domain between amino acids 369 and 403.

Verhofstede, C., K. Fransen, et al. (1996). "Isolation of HIV-1 RNA from plasma: evaluation of eight different extraction methods." Journal of Virological Methods **60**(2): 155.

<http://www.sciencedirect.com/science/article/B6T96-3W0NTKY-6/2/a3a12d1506e4ca8f8f19793c34cc7317>

The efficacy of eight different methods for the extraction of HIV-1 RNA from plasma was compared. The RNA preparation method that gave the best results by RT-PCR was the one described by Chomczynski and Sacchi (1987, *Anal. Biochem.* 162, 156-159). This method consists of a guanidine thiocyanate treatment followed by three phenol-chloroform-isoamylalcohol extractions and an ethanol precipitation. The disadvantage of this method is that it is time consuming and less suitable for the extraction of large series of samples. Moreover, due to the large number of procedural steps, there is a greater risk of sample mix-up or contamination. Of the single-step RNA purification methods, good results were obtained with the TRIzol method (Gibco Life Technologies, Paisley, UK) and with the extraction method offered by the NASBA kit (Organon Teknika, Turnhout, Belgium). The above single-step methods are recommended since both are sensitive enough to detect low copy numbers of HIV-RNA in the plasma of asymptomatic patients, and require only 2 h for completion. For most of the methods evaluated the inter-test variability was acceptable (mean variation coefficient between duplicate extraction varied between 17.3 and 47.3%). Inter-laboratory reproducibility was evaluated only for the TRIzol-method and found to be low (mean variation coefficient 63.4%).

Vesonen, M., H. Piiparinen, et al. (1996). "Detection of herpes simplex virus DNA in cerebrospinal fluid samples using the polymerase chain reaction and microplate hybridization." Journal of Virological Methods **59**(1-2): 1.

<http://www.sciencedirect.com/science/article/B6T96-3VYV049-D/2/81db02d5cb631156ed287cb194b19db9>

As conventional polymerase chain reaction (PCR) procedures are time-consuming and laborious, we developed and evaluated a rapid semi-automatic microplate method to detect the amplified PCR products. The use of PCR, with subsequent hybridization in microplates, is described for the detection of herpes simplex virus (HSV) DNA in cerebrospinal fluid samples. The principle of the method is based on two phases. Firstly, the amplification of the viral DNA in the sample is undertaken using a pair of primers of which one is biotinylated. Secondly, the amplified viral genomic sequences are bound to the wells of streptavidin-coated microplates and hybridized with digoxigenin-labeled oligonucleotide probes which are then detected using anti-digoxigenin antibody enzyme conjugates and either a photometric, fluorometric or luminometric substrate and microplate reader. The method is highly sensitive allowing the detection of as few as five purified DNA molecules. Compared to conventional gel electrophoresis followed by Southern blotting the established microplate hybridization is also much less time-consuming and involves less manual work. The applicability of the method is described for use as a routine diagnostic procedure for detection of early central nervous system infections caused by HSV-1 and HSV-2.

Vorndam, V., G. Kuno, et al. (1994). "A PCR-restriction enzyme technique for determining dengue virus subgroups within serotypes." Journal of Virological Methods **48**(2-3): 237.

<http://www.sciencedirect.com/science/article/B6T96-476F6FR-DT/2/6fe56633fe4d60a49583d278a9193c34>

The polymerase chain reaction (PCR) and restriction enzyme analysis were used to develop a rapid and simple procedure for identifying geographic subgroups of dengue virus within serotypes for epidemiologic investigations. The entire structural protein region of dengue viruses was amplified and the products were digested with the endonucleases AluI or DdeI. By comparing the restriction fragment length polymorphisms (RFLPs), we recognized dengue-2 and dengue-3 subgroups that corresponded to those previously determined by oligonucleotide fingerprinting or genomic sequencing. This procedure can be performed in 2 days without the use of radioisotopes, and results can be interpreted without computer analysis. For those analyses which require only subgroup affiliations, this is a useful tool for rapidly screening multiple virus isolates.

Weilguny, H. and R. P. Singh (1998). "Separation of Slovenian isolates of PVYNTN from the North American isolates of PVYN by a 3-primer PCR." Journal of Virological Methods **71**(1): 57.

<http://www.sciencedirect.com/science/article/B6T96-3SY3H5D-8/2/064363d0928e36dcee94b5a9422cbb11>

The potato tuber ringspot necrosis isolate of potato virus Y (PVYNTN) is a recently recognized and highly aggressive isolate of the PVYN group of strains. In order to screen specifically sources of resistance to PVYNTN a method to separate PVYNTN from PVYN is needed. To achieve this, 61 isolates from 13 imported and locally developed potato cultivars in Slovenia were studied. On the basis of the reactions in indicator plants *Nicotiana tabacum* cv. Samsun and *Solanum brachycarpum* and with a PVYN specific monoclonal antibody (4E7), all Slovenian isolates (SI-

NTN) were identified as PVYN. Using two primer pairs from the P1 gene of a Hungarian isolate of PVYNTN by a conventional single primer pair, reverse transcription polymerase chain reaction (RT-PCR) both PVYNTN and PVYN were amplified similarly. However, specific amplification of PVYNTN was achieved by a nested-PCR at an annealing temperature of 63[deg]C. A simplified form of the nested-PCR, termed 3-primer PCR was developed, which is applicable for large-scale testing of samples. Using the 3-primer PCR at annealing temperature of 63[deg]C, known mixtures of PVYNTN and PVYN were correctly separated. PVYNTN was detected in dormant tubers and leaves from all SI-NTN isolates. The 3-primer PCR was specific to PVYNTN and did not react with nine isolates of PVYN, 13 isolates of PVYo, one isolate of PVYC, six commonly occurring potato viruses and a viroid.

Weinberger, K. M., E. Wiedenmann, et al. (2000). "Sensitive and accurate quantitation of hepatitis B virus DNA using a kinetic fluorescence detection system (TaqMan PCR)." Journal of Virological Methods **85**(1-2): 75.

<http://www.sciencedirect.com/science/article/B6T96-3YGDCNX-8/2/ad601a0499d0fc4e745f78d7b4d9cd97>

The laboratory diagnosis of hepatitis B virus (HBV) infection is based mainly on serological assays. Yet the detection and quantitation of viral DNA is necessary when addressing directly the question of infectivity or when monitoring the viral load during therapy. Standard hybridization assays allow for exact quantitation, but their sensitivity is limited to 10⁵-10⁶ viral genomes per ml of serum. The most sensitive tests for HBV DNA are nested PCR systems, which recognize virtually one molecule of the target DNA per reaction. However, these assays only provide very coarse quantitative statements. To take advantage of both methods, a new assay for HBV DNA is described based on the commercial TaqMan(c) system. This assay is capable of quantifying HBV DNA from the theoretical lower limit up to 10¹⁰ genome equivalents per ml of serum and, thus, covers the complete range of naturally occurring states of infections. The method was calibrated on the basis of serial plasmid dilutions and compared with a well-established nested PCR system. More than 100 HBV positive sera and serial dilutions of the Eurohep standard for both ad and ay subtypes were analyzed. The assay reliably detected all HBV positive samples. It shows minimal run-to-run deviations, allows for quantitation that covers eight orders of magnitude, and finally, completely avoids the risk of cross-contamination by PCR products. Thus, this technique combines the sensitivity of PCR amplification and the quantitation potential of hybridization tests and it is time efficient and safer.

Whitby, J. E., P. R. Heaton, et al. (1997). "Rapid detection of rabies and rabies-related viruses by RT-PCR and enzyme-linked immunosorbent assay." Journal of Virological Methods **69**(1-2): 63.

<http://www.sciencedirect.com/science/article/B6T96-3S2BMBF-8/2/f1836ca8f6b43d0ddfedf1f8ae781af9>

A rapid detection method for the six established genotypes of rabies and rabies-related viral RNA using RT-PCR-ELISA is described. The detection of digoxigenin-labelled amplified products is performed by solution hybridization to two specific, biotin-labelled, capture probes, which are complementary to the inner region of the amplification products. The capture probe and amplified product hybrid are then immobilised on a streptavidin-coated microtitre plate, bound products are detected by an anti-DIG Fab fragment conjugated to peroxidase, and colorimetric reaction automatically measured. This method was up to 100-fold more sensitive than Southern blot hybridization, detecting 0.00002 TCID₅₀/ml of a genotype 1, classical rabies virus strain. The complete detection methodology from RT-PCR to PCR-ELISA detection could be completed within 10 h. Using this procedure, we were 100% successful in detecting 60 isolates from a

representative selection of the six established genotypes from all over the world. This test is a useful additional tool for the detection of the rabies and rabies-related viruses, which is easy to perform, rapid and highly sensitive.

Wilborn, F., T. Binder, et al. (1998). "Human herpesvirus type 6 variants identified by single-strand conformation polymorphism analysis." Journal of Virological Methods **73**(1): 21.

<http://www.sciencedirect.com/science/article/B6T96-3T2PCND-3/2/fd50b7c2d5c603a4b2e7bb4e2e164683>

Six human herpesvirus 6 (HHV-6) variants were analyzed for heterogeneity using the polymerase chain reaction (PCR) and single-strand conformation polymorphism (SSCP). Two independent DNA regions were selected: a fragment of the gene U11 (position 18966-21578) coding for a basic phosphoprotein, the major antigenic structural protein pp100; and a fragment from an open reading frame (ORF) area of the gene U67, previously referred to as 13R (position 102458-103519), coding for a product of unknown function. The two PCR systems based on the above DNA sequences yielded products of 187 bp and 223 bp, respectively. DNA obtained from three laboratory reference strains (U1102, R104 and St.W.) and from HHV-6 infected peripheral white blood cells of bone marrow transplant patients and blood donors was used to test the applicability of two different SSCP analysis systems for the identification of HHV-6 variants using amplicons derived by PCR from the two genomic regions described above (U11 [pp100], U67 [13R-ORF]). The generation of characteristic SSCP patterns enables the rapid differentiation of HHV-6 A and B strains for the classification of variants derived from clinical samples, reducing the need for expensive and time-consuming direct sequencing analyses.

Williamson, A.-L. and S. J. Dennis (1991). "The use of the polymerase chain reaction for the detection of human papillomavirus type 13." Journal of Virological Methods **31**(1): 57.

<http://www.sciencedirect.com/science/article/B6T96-47DM172-6/2/06e1159bac2c9ff344416aed504f309b>

Human papillomavirus type 13 (HPV-13) is associated with oral focal epithelial hyperplasia (FEH). The purpose of this study was to establish conditions for the application of polymerase chain reaction (PCR) to the specific detection and amplification of HPV-13 DNA. To design primers for HPV-13 a part of the HPV-13 genome was sequenced first: the smallest BamHI fragment (597 bp) of HPV-13 was subcloned and sequenced. The sequence was found to be part of a large open reading frame and had significant homology with the L1 gene of other HPVs. HPV-13 specific primers were designed to amplify a 240 bp fragment from the L1 gene by PCR. Conditions for PCR were standardized for this set of primers.

Yamaguchi, Y., T. Hironaka, et al. (1992). "Increased sensitivity for detection of human cytomegalovirus in urine by removal of inhibitors for the polymerase chain reaction." Journal of Virological Methods **37**(2): 209.

<http://www.sciencedirect.com/science/article/B6T96-476F5YM-5P/2/ba31f393d5b9280ecefaea1201d709a8>

The presence of inhibitors in urine interferes with the enzymatic reaction of the polymerase chain reaction (PCR) for detection of human cytomegalovirus (HCMV). To remove inhibitors, HCMV

virions in urine were precipitated with polyethylene glycol, or DNA was extracted from urine by the use of glass powder and subjected to PCR followed by Southern blot hybridization with alkaline phosphatase-linked oligonucleotide probes. These simple, rapid methods increased significantly the sensitivity of PCR for detection of HCMV in urine.

Yang, J.-H., J.-P. Lai, et al. (2002). "Real-time RT-PCR for quantitation of hepatitis C virus RNA." Journal of Virological Methods **102**(1-2): 119.

<http://www.sciencedirect.com/science/article/B6T96-450HBM7-1/2/a9ecfe7916725d98c498b1dece24ac36>

A newly developed real-time RT-polymerase chain reaction assay for quantitation of hepatitis C virus (HCV) RNA in human plasma and serum was applied. A pair of primers and a probe (molecular beacon) were designed that are specific for the recognition of a highly conservative 5'-non-coding region (5'-NCR) in HCV genome. HCV real-time RT-PCR assay had a sensitivity of 1000 RNA copies per reaction, with a dynamic range of detection between 10³ and 10⁷ RNA copies. The coefficient variation of threshold cycle (Ct) values in intra- and inter-runs were less than 1.37 and 4.66%, respectively. The real-time RT-PCR assay on the HCV sero-positive samples yielded reproducible data, with less than 2.09% of the inter-assay variation. In order to determine its potential for clinical diagnosis, real-time RT-PCR was used to examine the HCV RNA levels in plasma from sero-positive and negative subjects, showing that the assay is highly sensitive and has specificity of 100%. It was demonstrated that the real-time RT-PCR was able to amplify HCV RNA in reference sera with seven genotypes (1A, 1B, 2B, 3A, 4, 5A and 6A) that include six major HCV genotypes circulated in the world. Since HCV is a major pathogen of post-transfusion and community-transmitted non-A, non-B hepatitis, this assay has a broad application for basic and clinical investigations.

Ying, C., J. Van Pelt, et al. (1999). "Use of digoxigenin-labelled probes for the quantitation of HBV-DNA in antiviral drug evaluation." Journal of Virological Methods **81**(1-2): 155.

<http://www.sciencedirect.com/science/article/B6T96-3XMPJNX-N/2/09b8fc47c5efc19fda48eb13900d78f5>

The use of digoxigenin-labelled probes was studied for quantitation of HBV-DNA during antiviral drug evaluation. Digoxigenin (dig)-labelled probes were generated either via incorporation of dig-dUTP in a polymerase chain reaction (PCR) or a random priming reaction. Using the PCR-labelled probe (delineating a 523 bp fragment in the core gene of the HBV) as little as 1 pg of immobilized HBV-DNA could be detected following an 8 h exposure of the hybridized membrane. A close correlation ($r=0.95$) was found between the amount of HBV-DNA (range 2.5-200 pg) and the signal generated by the probe hybridized to its target DNA. By using a probe that was labelled with digoxigenin via random priming, the minimal quantity of immobilized HBV plasmid DNA that could be detected following an 8 h exposure was 4 pg, whereas a ³²P-labelled probe, generated in parallel by random priming, allowed the detection of 16 pg of HBV plasmid DNA following a 4-day exposure. The PCR-generated digoxigenin-labelled probe proved to be useful for antiviral drug evaluation, i.e. to detect HBV-DNA in total cellular DNA from HBV-positive hepatoma cells (HepG2.2.15) that had either been treated with reference antiviral agents or left untreated. The 50% effective concentrations (EC₅₀) that were calculated for inhibition of HBV-DNA production by lamivudine (3TC), penciclovir (PCV), lobucavir (LBV), adefovir (PMEA) and tenofovir (PMPA) were comparable to those reported in the literature. The use of digoxigenin-labelled probes thus appears to be a simple, convenient, rapid, reliable and non-radioactive method for use for anti-HBV screening. In addition, and in contrast to ³²P-labelled probes, digoxigenin-labelled probes can be stored for >1 year without loss of specific activity, which makes these probes particularly

attractive for large-scale antiviral drug evaluation purposes.

Yu, Q., N. Hu, et al. (2001). "Rapid acquisition of entire DNA polymerase gene of a novel herpesvirus from green turtle fibropapilloma by a genomic walking technique." Journal of Virological Methods **91**(2): 183.

<http://www.sciencedirect.com/science/article/B6T96-426XYG8-B/2/4d5ace1b6ced9aff356ac5778285f744>

A 4837-bp sequence of a newfound green turtle herpesvirus (GTHV), implicated in the etiology of green turtle fibropapilloma, was obtained from tumor tissues of a green turtle with fibropapilloma using a genomic walking method based on restriction enzyme digestion, self-ligation and inverse polymerase chain reaction (IPCR). The 4837-bp sequence was 56.23% G/C rich and contained three nonoverlapping open reading frames (ORF). The largest ORF (3507-bp) encoded the DNA polymerase gene (pol gene), which exhibited a high degree of homology at both amino acid and nucleotide levels with the DNA pol genes of human and animal herpesviruses, with a predicted protein of 1169 amino acids and molecular weight of 132.6 kilodaltons. The ATG at 518 to 520 was the first initiation codon in the ORF and was presumed to be the first methionine codon of the pol gene. Phylogenetic analysis, based on the amino acid sequence of the GTHV DNA pol gene and the corresponding regions of other known human and animal herpesviruses, indicated that GTHV belonged to the Alphaherpesvirinae subfamily. The upstream ORF of the pol gene encoded the N-terminal region of the GTHV homologue of the DNA-binding protein gene, whereas the downstream ORF was the C-terminal region of a gene which was homologous to ORFs conserved in human and animal herpesviruses, i.e., herpes simplex virus 1 (HSV1) gene UL31, Epstein-Barr virus (EBV) gene BFLF2, equine herpesvirus 1 (EHV1) gene 29, and alcelaphine herpesvirus 1 (AHV1) hypothetical protein 69 gene. The arrangement of these three genes in GTHV genome was identical to that seen in other alphaherpesviruses. The sequence and location of the DNA pol gene in the GTHV genome should greatly facilitate future studies of the viral life cycle.

Zhang, H., B. Soteriou, et al. (1997). "Characterisation of genomic RNA of Coxsackievirus B3 in murine myocarditis: reliability of direct sequencing of reverse transcription-nested polymerase chain reaction products." Journal of Virological Methods **69**(1-2): 7.

<http://www.sciencedirect.com/science/article/B6T96-3S2BMBF-2/2/386b5d4dd1c82c240be7445ad7a5aba5>

SWR mice develop viral myocarditis histologically similar to the human disease following inoculation with a cardiovirulent Coxsackievirus B3 (CVB3), reactivated from a sequenced cDNA clone of Nancy strain. A sequence of 215 nucleotides, or 628 nucleotides in representative cases, of the 5'non-translated region (5'NTR) of CVB3 genome was amplified from myocardial samples of the infected mice by reverse transcription-nested polymerase chain reaction (RT-NPCR). In order to verify the viral nucleotide sequence and detect the mutation frequency of the viral RNA, the nucleotide sequence of NPCR products were determined by direct sequencing in both orientations. The amplified products from mouse heart on day 1-13 post-inoculation were sequenced and, in each case, the consensus sequence was identical to the published sequence of CVB3 (Nancy strain). To evaluate further the reproducibility of these techniques, three tissue samples from the same infected mouse heart were processed independently. Sequences of their RT-NPCR products were identical to each other as well as to the published sequence. When two attenuated CVB3 mutants were amplified and sequenced, single mutations were detected. To evaluate the overall fidelity of these two combined techniques, genomic RNA of a different CVB3 Nancy strain stock, Coxsackievirus A9 or poliovirus sabin 1 was amplified and the NPCR

products sequenced. Each product showed 100% homology with its published sequence. These results demonstrate that the coupled technique of the enterovirus RT-NPCR with direct sequencing of NPCR products generates accurate consensus sequence data and this technique proved to be useful in verification of enteroviral amplicons and in detection of nucleotide mutations. In addition, a low mutation frequency was found in the 5'NTR of CVB3 detected in myocardial samples of immunocompetent mice up to 13 days.

Zimmermann, W., R. Durrwald, et al. (1994). "Detection of Borna disease virus RNA in naturally infected animals by a nested polymerase chain reaction." Journal of Virological Methods **46**(2): 133.

<http://www.sciencedirect.com/science/article/B6T96-476F69S-BC/2/b2c6ea7294f02a31ba9e8a947b4de423>

Borna disease virus in naturally infected horses, a donkey and sheep was detected for the first time by amplification of viral RNA using PCR. In contrast to a control group of healthy horses, brain tissue was positive by this assay in all animals with neurological symptoms. The use of a second round of PCR with nested primers following Southern hybridization confirmed the specificity and increased the sensitivity of the test. Comparison with conventional methods recommends this technique for monitoring of BDV infections at a molecular level.

Zingg, W., W. Bossart, et al. (1999). "Detection and quantification of cell-free Epstein-Barr virus by polymerase chain reaction and subsequent DNA enzyme immunoassay." Journal of Virological Methods **79**(2): 141.

<http://www.sciencedirect.com/science/article/B6T96-3WJDTS6-3/2/20d346e54823d0c479dde2d2deef0326>

Amplification by polymerase chain reaction and subsequent DNA enzyme immunoassay (DEIA) were employed to determine the number of genome equivalents of cell-free Epstein-Barr virus (EBV) DNA in peripheral blood. The assay detected cell-free EBV DNA in the serum of 14 out of 18 patients with primary, productive EBV infection (sensitivity 77.7%) but not in healthy EBV carriers with latent infection (specificity 100%). Our assay has the potential for a clinical diagnostic tool to monitor patients at risk for EBV reactivation and productive infection with subsequent EBV-induced lymphoproliferative diseases.

Jpn. J. Clin. Oncol. (4)

Ishida, H., H. Furukawa, et al. (2002). "The Novel Germline Mutation of hMSH2 Gene in a Case of a Colon Cancer Patient Without Family History." Jpn. J. Clin. Oncol. **32**(7): 266-269.

<http://jjco.oupjournals.org/cgi/content/abstract/32/7/266>

Hereditary non-polyposis colorectal cancer (HNPCC) is generally found from the patient's family history. The functional disorder of mismatch repair genes has been reported to be responsible for HNPCC. The proband was a 28-year-old Japanese female who was admitted to our hospital with

a diagnosis of descending colon cancer. Although there was no previous or family history of malignant disorders within the first- and second-degree relatives, the early onset of colon cancer prompted genetic analysis with suspicion of HNPCC. PCR analysis of the primary tumor showed DNA replication errors at the six microsatellite regions. PCR/direct sequential analysis of the peripheral lymphocytes revealed a germline frameshift mutation due to deletion of TTCAA at nt. position from 650 to 654 in exon 4 of the hMSH2 gene. According to the Human Mutation Database and International Collaborative Group on HNPCC Database, this type of the frameshift mutation is the first report in the hMSH2 gene.

Kamoto, T., Y. Isogawa, et al. (2005). "Association of a Genetic Polymorphism of the E-cadherin Gene with Prostate Cancer in a Japanese Population." *Jpn. J. Clin. Oncol.* **35**(3): 158-161.

<http://jjco.oupjournals.org/cgi/content/abstract/35/3/158>

The E-cadherin gene has been identified as having a physiological role in cellular attachment, and is hypothesized to participate in carcinogenesis. A polymorphism (an A to C substitution) in the 5'-untranslated region has a direct effect on E-cadherin gene transcriptional regulation. We explored the association between E-cadherin gene polymorphism and the risk of prostate cancer in a Japanese population. The subjects consisted of 236 patients with prostate cancer, 209 benign prostatic hyperplasia (BPH) patients and 139 male controls. A marginally significant difference was found between prostate cancer patients and male controls ($P = 0.053$). No significant difference was observed between prostate cancer and BPH patients. When patients with prostate cancer were divided into two groups, stage A+B and stage C+D, a significant difference was observed between progressive cancer patients (stage C+D) and male controls (odds ratio = 1.93, $P = 0.016$). It is possible that the presence of one A allele resulted in an increased risk of cancer progression.

Nomoto, K., M. Maekawa, et al. (2002). "Methylation Status and Expression of Human Telomerase Reverse Transcriptase mRNA in Relation to Hypermethylation of the p16 gene in Colorectal Cancers as Analyzed by Bisulfite PCR-SSCP." *Jpn. J. Clin. Oncol.* **32**(1): 3-8.

<http://jjco.oupjournals.org/cgi/content/abstract/32/1/3>

Background: The expression level of human telomerase reverse transcriptase (hTERT) is correlated with telomerase activity and is expressed at high levels in malignant tumors. It is of interest whether expression of hTERT is regulated by methylation of the CpG island in the promoter of the hTERT gene. We examined hTERT expression and methylation status of the hTERT and other genes including p16. Methods: We analyzed methylation status by bisulfite treatment and polymerase chain reaction with single-strand conformation polymorphism analysis (PCR-SSCP) and expression of the hTERT by RT-PCR, in 13 cancer cell lines, eight white blood cell samples and 24 colorectal cancer tissues. Results: In the cancer cell lines, hTERT was expressed and the CpG island of the hTERT promoter was methylated. Most colorectal cancer tissues showed similar results. The promoter of hTERT was methylated in six cases, partially methylated in 17 cases and unmethylated in one case. All cases with methylation of hMLH1 or p16 also showed methylation of hTERT; however, some of the cases lacking p16 methylation also had hTERT methylation. Conclusion: Increased expression of hTERT is related to hypermethylation of hTERT in colorectal cancerous tissues as well as some cancer cell lines and discordant with hypermethylation of p16.

Tsurusako, S.-I., H. Tanaka, et al. (2002). "Low Incidence of p53 Mutations in Well-differentiated Tongue Squamous Cell Carcinoma in Japan." Jpn. J. Clin. Oncol. **32**(9): 327-331.

<http://jjco.oupjournals.org/cgi/content/abstract/32/9/327>

Background: Despite an increasing number of patients suffering from squamous cell carcinomas of the tongue, little is known about the molecular mechanisms involved in the origin and development of these neoplasms. Methods: We screened microdissected tongue squamous cell carcinoma (TSC) specimens from 28 consecutive, previously untreated, Japanese patients for mutations in the p53 tumor-suppressor gene single-strand conformation polymorphism analysis (exons 5, 6, 7, 8) and direct genomic sequencing. Results: Among them, 24 tumor specimens were well differentiated, three moderately and one poorly differentiated, according to the WHO classification. Mutations in the p53 tumor-suppressor gene were detected in only two out of the 28 (7%) tumor specimens. One was well differentiated and the other was poorly differentiated. Conclusions: Our results suggest that p53 gene mutations are less frequent in well differentiated TSC. These results indicate that mutations in the p53 gene may not be strongly involved in the development of well differentiated TSC.

Lebensmittel-Wissenschaft und-Technologie (1)

Berthoud, H., F. Chavagnat, et al. (2005). "Comparison of partial gene sequences encoding a phosphoketolase for the identification of bifidobacteria." Lebensmittel-Wissenschaft und-Technologie **38**(1): 101.

<http://www.sciencedirect.com/science/article/B6WMV-4CPD5SX-1/2/189b1b8e5513319bb0125a030d6c1c8b>

In this study, a new identification method for Bifidobacterium species based on sequencing of a partial xylulose-5-phosphate/fructose-6-phosphate phosphoketolase gene (xfp) was evaluated. Approximately 500 bp sequences from 68 different strains including 34 type strains were compared. The results showed that this method discriminated between all bifidobacteria, generally with greater accuracy than 16S rDNA sequence analysis. It even clearly distinguished B. longum biovar infantis from B. longum biovar longum and B. longum biovar suis, as well as B. animalis from B. lactis.

Legal Medicine(13)

Imaizumi, K., K. Noguchi, et al. (2005). "DNA typing of bone specimens--the potential use of the profiler test as a tool for bone identification." Legal Medicine **7**(1): 31.

<http://www.sciencedirect.com/science/article/B6W7W-4DFT078-3/2/c87afd52a4262b65ab827a09ce3454f7>

Twenty-six bone DNA identification cases are described. The postmortem periods of the studied remains ranged from three days to over 30 years, and the locations where the remains were found varied resulting in a variety of postmortem conditions. Nuclear DNA typing using an AmpFLSTR Profiler kit and mitochondrial DNA (mtDNA) typing of hypervariable regions 1 and 2 (HV1 and HV2) in a control region were performed both with decalcified and non-treated bone powder samples. Decalcification was shown to improve the success of DNA typing. The nucleotide sequences of the HV1 and HV2 regions were successfully determined in all cases examined. Nuclear DNA typing was very successful, more than half of the loci were typed during multiple amplifications (10 loci in one reaction) in 23 cases. Polymerase chain reaction (PCR) inhibition was observed in five cases including three samples that were found buried in soil. This inhibitory effect was identified as the result of unbalanced multiple PCR during the profiler test. These results revealed that DNA typing targeting nuclear DNA is a potentially powerful tool for bone identification.

Inagaki, S., Y. Yamamoto, et al. (2002). "Typing of Y chromosome single nucleotide polymorphisms in a Japanese population by a multiplexed single nucleotide primer extension reaction." Legal Medicine 4(3): 202.

<http://www.sciencedirect.com/science/article/B6W7W-46NY92R-7/2/74250d16c167ccd263fe2064cdb49697>

We have developed a new method for typing single nucleotide polymorphisms (SNPs) on the human Y chromosome based on a multiplexed single nucleotide primer extension. This method has the advantage that several SNPs are typed rapidly and simultaneously. We examined 15 different SNP loci on Y chromosome, M9, M105, M122, M125, M128, M130, SRY465, IMS-JST006241, IMS-JST006841, IMS-JST002611, IMS-JST003305, IMS-JST008425, IMS-JST021354, IMS-JST021355 and IMS-JST055457, in 159 Japanese males. From the typing results of these 15 loci, we found 13 haplotypes. Gene diversity for each locus ranged from 0.025 to 0.486 and the haplotype diversity was estimated to be 0.838. This method could be readily applied for personal identification and paternity testing.

Ishida, K., B.-L. Zhu, et al. (2002). "A quantitative RT-PCR assay of surfactant-associated protein A1 and A2 mRNA transcripts as a diagnostic tool for acute asphyxial death." Legal Medicine 4(1): 7.

<http://www.sciencedirect.com/science/article/B6W7W-44CXRJJ-2/2/2aad436a6d7b1bce2371b397c4fa1ba1>

Although an immunohistochemical investigation of pulmonary surfactant-associated protein A (SP-A) suggested a characteristic increase in fatal asphyxiation, no particular change was observed in the total amount of SP-A mRNA. SP-A is encoded by two highly similar genes, SP-A1 and SP-A2, which are differentially regulated in the expression. In the present study, to investigate the molecular pathology of SP-A, we established a method for quantitative RT-PCR assay of SP-A1 and SP-A2 mRNA transcripts. Using this method, fatalities from acute mechanical asphyxia (n=12) and drowning (n=9) were examined in comparison with control groups (n=17) of acute myocardial infarction (n=11) and peracute death due to brain lacerations (n=6). The SP-A1/A2 ratio (mean value) was markedly elevated in mechanical asphyxia (6.72) and drowning (5.64), whereas it was low in controls (acute myocardial infarction, 2.80; brain lacerations, 2.56). The analysis of the SP-A1/A2 ratio may assist interpretation of the molecular alterations of SP-A related to acute asphyxial death.

Kobayashi, T. and A. Akane (2000). "ABO genotyping by inverse PCR technique." Legal Medicine 2(1): 15.

<http://www.sciencedirect.com/science/article/B6W7W-44G8C9H-1X/2/9a4db775a139c33fa45c365758c3db6d>

Inverse PCR technique was applied to type three major alleles (A1, B and O1) of the ABO blood group by simultaneously detecting separated allele-determining nucleotides (the 261st base in exon 6 and the 796th and 803rd nucleotides in exon 7) of the ABO gene. A sequence of about 1.7 kb from exons 6 to 7 of each allele was amplified, both termini of the fragment ligated, and allele-typing performed by the inverse PCR-restriction fragment length polymorphism (IP-RFLP) and allele-specific inverse-PCR (ASIP) methods. For intramolecular ligation, primers for the first PCR were designed to have Acc I-restriction sites within the sequences, and both termini of the 1.7-kb fragment were digested with Acc I. Using the IP-RFLP method, the inverse PCR product was digested with Kpn I, Nla III and Dde I, A1, B, O1-standard (OA) and O1-variant (OG) alleles were detected as 365-bp, 272-bp, 193-bp and 128-bp fragments, respectively. By the ASIP method using four allele-specific primers, 222-bp, 124-bp and 232-bp fragments were amplified from A1, B and O1 templates, respectively. These techniques would be applicable to detecting separated polymorphic regions of some other genes.

Michino, J., Y. Hata, et al. "Demonstration of A antigen and A allele of ABO histo-blood group in nail in a case with the absence of A antigen and anti-A antibody in blood." Legal Medicine In Press, Corrected Proof <http://www.sciencedirect.com/science/article/B6W7W-4FHKK65-1/2/6b7a481100166eda9371a00055e5bc8c>

We report a case with the inconsistency that the red blood cells lacked both A- and B-antigens while the serum showed reactivity with control B-red cells but not with A-red cells. A- and B-antigens were examined by serological blood typing and immunohistochemical staining, and DNA analyses were performed using polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP), DNA sequencing, and hot-stop PCR. A-antigens were demonstrable in the nail of the subject by serological study and immunostaining. DNA analyses showed that the nail retained a small amount of A-allele comparing to that of O-allele. Those genomic analyses of ABO genes were useful for demonstration of A allele in the nail of an individual with the absence of A antigen on red blood cells and the corresponding antibody in serum.

Mitani, T. and A. Akane (2003). "Mung bean nuclease treatment improves Se genotyping by allele-specific inverse polymerase chain reaction amplification." Legal Medicine 5(4): 233.

<http://www.sciencedirect.com/science/article/B6W7W-49PRDRY-5/2/a28e9cfd0f4e22e42bddfe7f0273f440>

The allele-specific inverse polymerase chain reaction (PCR) technique, which has been explored to detect two linked polymorphic regions simultaneously, was applied to genotype the Se system. The major alleles of the Se system in Japanese are Se, sej defined by a single nucleotide substitution in the Se allele, and sefus generated by recombination between the Sec1 and FUT2 genes. The first PCR products using gene-specific primers were self-ligated, and each allele was detected by the second inverse-PCR using allele-specific primers. The 340, 331 and 353-bp products were finally amplified from Se, sej and sefus templates, respectively. The first PCR products without mung bean nuclease treatment were not self-ligated and non-specific fragments were amplified in the second PCR, suggesting that non-templated adenylation occurred at the termini during the first PCR. Nuclease digestion of the first PCR products that blunts their termini

was found to reduce interference of non-templated adenylation with the intramolecular ligation and to improve the genotyping markedly. This modified allele-specific inverse-PCR method is applicable to analyze haplotypes consisting of separated single nucleotide polymorphisms and recombinant genes.

Mitani, T., H. Tsujita, et al. (2000). "A case of DNA analysis of ABO blood group variant allele A2." Legal Medicine 2(4): 197.

<http://www.sciencedirect.com/science/article/B6W7W-44G8CDV-37/2/c0849594b3bd4abba78e9f99d49a28be>

The ABO phenotype of a bloodstain (B) on a knife that was used as a weapon in an attempted murder case was found to be different from that of the Peruvian victim's blood (AB). Serological analysis showed that the A-antigenicity was much weaker than B antigenicity, suggesting that the victim's phenotype was A2B or A3B. So, the ABO genotypes of the knife bloodstain and the victim's blood were determined by DNA analysis. The 261st G deletion, specific to the O1 allele, was not detected in the specimens by restriction fragment length polymorphism analysis. Also, the 871st A, specific to the A3 allele, was not found by the allele-specific amplification method. Amplified product length polymorphism and direct sequencing methods finally demonstrated that the typical B sequence was found in one allele and a single C deletion in the 1,059th-1,061st C stretch in the other allele, indicating that the ABO phenotype of the bloodstain and victim's blood were A2B.

Mitani, T., H. Tsujita, et al. (2002). "Se genotyping following allele-specific polymerase chain reaction amplification." Legal Medicine 4(3): 193.

<http://www.sciencedirect.com/science/article/B6W7W-46NY92R-5/2/c500ad24184da7d34998b0624088fcdf>

The polymorphism of the Sec2 gene, which determines Se blood type, has been reported. This study presents an Se genotyping system by the allele-specific polymerase chain reaction amplification method. The Se, sej and sefus alleles were amplified using allele-specific primers. The Sec1, Sec2 and sefus genes were analyzed by DNA sequencing. The 299-bp Se, 146-bp sej and/or 312-bp sefus allele-specific products were amplified and detected in the native polyacrylamide gel. The 314th-316th nucleotides of the Sec1 gene were CCC, which were different from the nucleotides GGG reported previously by Kelly et al. [J Biol Chem 270 (1995) 4640]. This Se genotyping system is a simple method available for the forensic science field in Japan. The crossover region of the sefus gene is a 164-bp stretch corresponding to the regions between the 253rd and 416th of the Sec1 gene and between the 211th and 374th of the Sec2 gene.

Ogata, Y., T. Yamaba, et al. "Improvement of a multiplex PCR system for DYS441, DYS442, DYS443, DYS444 and DYS445, and a population study in 340 Japanese males." Legal Medicine In Press, Corrected Proof <http://www.sciencedirect.com/science/article/B6W7W-4F29HMY-2/2/11ef3690e341fc2ef3f8841231af91de>

A multiplex PCR system for five Y-STRs (DYS441, DYS442, DYS443, DYS444 and DYS445) has been improved to increase the probability of obtaining a DNA typing result from aged samples. Newly designed PCR primers for amplification of the DYS441 and DYS442 loci and optimization

of PCR conditions enabled successful typing from blood and semen stains that had been stored for more than seven years at room temperature. Analysis of 340 Japanese males revealed 7, 5, 6, 5 and 4 alleles at the DYS441, DYS442, DYS443, DYS444 and DYS445 loci, respectively, yielding 122 haplotypes with a cumulative haplotype diversity of 0.97.

Sato, Y., M. Hayakawa, et al. (2003). "HLA typing of aortic tissues from unidentified bodies using hot start polymerase chain reaction-sequence specific primers." Legal Medicine 5(Supplement 1): S191.

<http://www.sciencedirect.com/science/article/B6W7W-47PG72T-VI2/b078826e1f8ff1c4773883cc890098dd>

This study investigated the identification of unidentified bodies through HLA DNA typing of aortic tissues. Eight aortas were collected at autopsy from six bodies found in water, one burnt body, and one mummified body, respectively. DNA was extracted from 10-20 mg of aortic tissue with a PUREGENE(R) DNA Isolation Kit and phenol/chloroform. HLA (A, B, DR or DQ locus) alleles were typed using the hot start polymerase chain reaction-sequence specific primers (PCR-SSP) method with a Dynal AllSet+(TM) SSP "low resolution" kit for each locus. The aorta was still retained in degraded samples, those from the drowned, the burnt, and the mummified bodies. In each case, approximately 0.04-3.84 [μ]g of DNA was recovered from 1 mg of fixed tissue. We typed 8/8 for the DR, 4/4 for the DQ, 3/3 for the A, and 3/3 for the B locus from the samples. Based on these results and the finding that DNA extraction is easier from the aorta than from other samples such as bone or tooth, we considered this method to be useful for forensic samples.

Tanaka, M., N. Yamashita, et al. (2001). "RHC/c genotyping based on polymorphism in the promoter region of the RHCE gene." Legal Medicine 3(4): 205.

<http://www.sciencedirect.com/science/article/B6W7W-44B1Y7K-2I2/7a11b975f09f6bf92139ccfcde7eebe9>

Designing of PCR tests for the RHC allele is difficult because of the high DNA sequence homology between RHC and RHD genes, which differ by only a one-nucleotide substitution at position 48 in exon 1 of the RHCE gene. We sequenced the promoter region of the RHCE gene, and compared our results with the reported sequence. Genomic DNA was prepared from blood samples collected from 656 Japanese donors. The DNA segment encompassing the promoter region and exon 1 of the RHCE gene from 30 donors was amplified by PCR and analyzed by DNA sequencing. Four nucleotide differences between RHC/c and RHD were found at positions -468, -304, -58, and -46. On the basis of the nucleotide differences at positions -468 (RHCE vs. RHD) and -292 (RHC vs. RHc), we then developed a novel polymerase chain reaction-restriction fragment length polymorphism (PCR-RFLP) method for RHC/c genotyping. Analysis of the genomic DNA from the 656 donors revealed that this method could discriminate RHC from RHc, irrespective of the RHD genotype, with only a few exceptions. The combination of our system and the intron 2-based PCR-RFLP method previously reported may prove to be more accurate than either of the methods alone, and therefore, useful and valuable for RHC/c genotyping.

Tsukada, K., K. Takayanagi, et al. (2002). "Multiplex short tandem repeat typing in degraded samples using newly designed primers for the TH01, TPOX, CSF1PO, and vWA loci." Legal Medicine 4(4): 239.

<http://www.sciencedirect.com/science/article/B6W7W-473VVB-4/2/38fbbc45d0eba3df5040f1a71ee36bbb>

We performed multiplex polymerase chain reaction (PCR) for the TH01, TPOX, CSF1PO, and vWA loci using a newly designed pair of primers that yield smaller fragments than reported previously [Fujii et al., J Hum Genet 45 (2000) 303; Lederer et al., Int J Legal Med 114 (2000) 87]. These loci can be detected in the range of 74-143 bp amplifying products. This system required genomic DNA in a range of 80 pg to 2 ng, and proved to be a sensitive typing method. We compared our system against the GenePrint Fluorescent STR Multiplex Systems CTTv (Promega, Madison, WI, USA), using DNA extracted from old bloodstains left to stand for 17-26 years at room temperature. With our designed system, all allele-typing efforts were successful in the range of 1-5 ng DNA, while no signal peaks were detected, even with when using 10 ng of DNA GenePrint Fluorescent STR Multiplex Systems CTTv.

Yasuda, T., R. Iida, et al. (2004). "A novel 56-bp variable tandem repeat polymorphism in the human deoxyribonuclease I gene and its population data." Legal Medicine 6(4): 242.

<http://www.sciencedirect.com/science/article/B6W7W-4D4CYM6-3/2/b6d2fc3fd19e3baff81a8299bb012a24>

This study confirms the presence of a novel variable number of tandem repeats polymorphism, designated as HumDN1, in intron 4 of the human deoxyribonuclease I (DNase I) gene. Genotyping was performed without difficulty by PCR-amplification and separation by agarose gel electrophoresis in 423 Japanese, originating from four geographically diverse areas in Japan, and 89 Germans. The HumDN1 allele variability was due to different numbers of 56-bp repeat sequences, and five different alleles were distinguished with apparent size between 364 and 588 bp. Although there was a general uniformity for the polymorphism in the Japanese population, significant differences in genotype distribution were found between the Japanese and German populations. Furthermore, linkage disequilibrium between the HumDN1 and DNase I protein polymorphisms was revealed.

Leukemia Research (39)

Baker, E. J., D. A. Gerard, et al. (2002). "HL-60 cell growth-conditioned medium is an effective inducer of myeloperoxidase expression in K-562 human leukemia cells." Leukemia Research 26(11): 1017.

<http://www.sciencedirect.com/science/article/B6T98-45F8XF0-2/2/9fbb55bc4814f88f0861b34705005cff>

K-562 cells were cultured in HL-60 cell growth-conditioned medium (GCM) for up to 96 h. Myeloperoxidase (MPO) mRNA was transiently detected by reverse transcription-polymerase chain reaction (RT-PCR) techniques at 12, 24, and 48 h. The de novo expression of MPO protein was subsequently detectable by intracellular flow cytometry at 24, 48, 72 and 96 h. Immunogold staining and cytochemical analysis demonstrated granularly-sequestered MPO in approximately 40% of HL-60 GCM-cultured cells after 48 h of culture. The sequential detection of MPO mRNA and MPO biosynthesis is considered an indicator of serial maturation evocative of myeloblastic cells, and suggest that K-562 cells maintain the ability to differentiate along this lineage.

Busque, L., J. R. Ilaria, et al. (1994). "Clonality analysis of childhood all in remission: No evidence of clonal hematopoiesis." Leukemia Research **18**(2): 71.

<http://www.sciencedirect.com/science/article/B6T98-4BY4PSJ-S/2/40bba214793b8b2f88a7a0b2ec272542>

We studied 98 female patients in remission (2-240 months) from childhood ALL to determine the clonality status of their hematopoiesis. Thirty-one (31.6%) were heterozygous at the PGK locus for the BstX1 endonuclease restriction site, permitting X-linked clonality assays to be performed. Two patients were in relapse at the time of study and were excluded. We used the PGK-PCR clonality assay (PPCA) to analyze DNA from PMN and mononuclear cells of the remaining 29 female patients. All (29/29) patients demonstrated polyclonal hematopoiesis. These data show that remission from childhood ALL involves reestablishment of polyclonally derived hematopoiesis in all patients studied.

Chim, C. S., Y. L. Kwong, et al. (2004). "Methylation profiling in multiple myeloma." Leukemia Research **28**(4): 379.

<http://www.sciencedirect.com/science/article/B6T98-49J8T38-5/2/d448bddef37302cc24b2f6fc4e107973>

Background: We analysed the methylation status of a panel of 10 genes including p15, p16, DAPK, p73, VHL, E-CAD, MGMT, RAR[beta], RIZ1, and ER. Methods: The gene promoter methylation status was studied by methylation-specific polymerase chain reaction (MSP) with primers for methylated (M-MSP) and unmethylated (U-MSP) DNA in the bone marrow of 13 patients with myeloma, and one patient with plasmacytoma. Result: None of the 10 genes tested were methylated in eight normal bone marrow samples. For the positive control, the sensitivity of M-MSP ranged from 1×10^{-2} for E-CAD and MGMT, to 1×10^{-4} for p73. Of the eight diagnostic myeloma marrow samples, hypermethylation of p15, p16, E-CAD, DAPK and ER occurred in six (75%), four (50%), seven (87.5%), eight (100%), and six (75%) patients. Similarly, of the five samples from patients who progressed from plateau phase, hypermethylation of p15, p16, E-CAD, DAPK, and ER occurred in five (80%), two (40%), five (100%), five (100%), and three (60%). None of the cases had hypermethylation of RIZ1, p73, VHL, RAR[beta], and MGMT. At diagnosis, all patients had concurrent hypermethylation of at least three genes, and five (62%) had concurrent methylation of four or more genes. One patient with plasmacytoma had methylation of E-CAD, ER, and DAPK. Conclusion: p15, p16, ER, DAPK, and E-CAD (but not RAR[beta], p73, VHL, RIZ1, and MGMT) were frequently methylated in MM at both diagnosis and disease progression. Future studies of larger scale are needed to identify the genes responsible for disease progression.

Curry, J. D. and M. T. Smith (2003). "Measurement of SIL-TAL1 fusion gene transcripts associated with human T-cell lymphocytic leukemia by real-time reverse transcriptase-PCR." Leukemia Research **27**(7): 575.

<http://www.sciencedirect.com/science/article/B6T98-47GHMRS-1/2/c9c5178d5b0a0e95caef2fe167764065>

TAL1 disruption at 1p32 [del(1p)] is a common rearrangement in the development of T-cell acute lymphocytic leukemia (T-ALL). The del(1p) are usually interstitial 90 kb deletions placing TAL1

under control of the SCL interrupting locus (SIL) gene forming the SIL-TAL1 fusion product. A reverse transcriptase real-time PCR assay to quantify SIL-TAL1 fusion genes is described. A SIL-TAL1 fusion gene RNA transcript was built that permitted absolute standard curves to be generated. Sensitivity of the RT-PCR assay was determined to be 10 cells (CEM cell line) in 10⁶ human lymphocytes. Peripheral blood lymphocytes from 10 healthy adults and 10 neonates were assayed. None of the samples showed any SIL-TAL1 expression. However, when lymphocytes from three adults were cultured in vitro the SIL-TAL1 transcript was detectable in the RNA isolates. No RAG2 expression was detected in these expanded samples, suggesting that the clones bearing the SIL-TAL1 fusion gene may have existed at low levels prior to the ex vivo expansion.

de Souza Fernandez, T., J. Menezes de Souza, et al. (1998). "Correlation of N-ras point mutations with specific chromosomal abnormalities in primary myelodysplastic syndrome." Leukemia Research **22**(2): 125.

<http://www.sciencedirect.com/science/article/B6T98-3T0S8SP-4/2/c46a2749dacc4c7ed348d4c7ded628bf>

A cytogenetic and N-ras point mutation study was done in patients with primary myelodysplastic syndrome (MDS) from Rio de Janeiro, Brazil, in order to evaluate the progression of preleukemic states to overt leukemia. Cytogenetic analysis was performed in 50 patients with MDS and clonal chromosomal abnormalities were detected in 19 (38%) of them. Patients with refractory anemia (RA) or with ringed sideroblasts (RARS) presented normal karyotypes or single abnormalities as del(5q) or -Y, while patients in more advanced states as RA with excess of blasts (RAEB), RAEB in transformation (RAEB-t) and chronic myelomonocytic leukemia (CMML) showed complex karyotypes and single abnormalities involving chromosomes 7 or 8, which were related to poor prognosis and elevated risk of transformation to acute myeloid leukemia (AML). The frequency of ras activation was studied in these 50 patients with MDS. Samples of bone marrow were screened for oncogenic point mutations by DNA amplification followed by oligonucleotide hybridization analysis (PCR-ASO) at codon 12 of N-ras proto-oncogene. We detected N-ras point mutations in 21 patients (42%). Progression from MDS to AML was observed in 9 patients (18%). The correlation analysis between N-ras point mutations and specific chromosomal abnormalities indicated that although mutated N-ras was found in cells with del(5q) and monosomy 7, cells with those abnormalities and normal N-ras were also identified. Otherwise trisomy of chromosome 8 showed a correlation with N-ras point mutations and in all cases, patients showed progression of MDS to AML during the follow-up study. MDS comprises a heterogeneous group of hematopoietic disorders and probably several steps are implicated in the evolution to AML. In this work we suggest that one possible pathway of leukemogenesis in MDS includes N-ras point mutations in association with trisomy of chromosome 8.

Delforge, M., V. Raets, et al. (2003). "Amifostine does not preferentially stimulate the growth of residual polyclonal progenitor cells in myelodysplastic syndromes." Leukemia Research **27**(7): 593.

<http://www.sciencedirect.com/science/article/B6T98-46RD13X-2/2/f61e97d9e530df63640f976c892d5d04>

Amifostine is a phosphorylated aminothiols that has besides anti-oxidative and cytoprotective properties, also survival- and growth-promoting effects on hematopoietic progenitor cells. Clinical studies have demonstrated that infusions with amifostine are able to increase erythro-, myelo-, and thrombopoiesis in some patients with myelodysplastic syndromes (MDS). Since clonal and non-clonal progenitors can coexist in early phase MDS, we have studied if amifostine exerts a selective growth-promoting effect on clonal or non-clonal cells. For this purpose, purified CD34+

marrow progenitors from nine female MDS patients were grown in short- and long-term cultures. Clonality was studied on individual colonies using polymorphisms in the human androgen receptor assay (HUMARA) locus. Three patients had growth of residual non-clonal progenitors at baseline. Continuous exposure to 100 nM amifostine exerted a growth-promoting effect on progenitors in 50% of the patients. HUMARA patterns of individual colony-forming unit granulocyte macrophage (CFU-GM; 5/9) and 5 week long-term culture-initiating cells (LTC-IC; 2/9) were compared without and with amifostine exposure. We did not observe preferential stimulation of clonal or non-clonal progenitors. Based on these results, the stimulation of committed and immature progenitor growth in MDS by amifostine, is non-selective and does not favor nor suppress the growth of residual non-clonal cells.

Diamant, M., M. B. Hansen, et al. (1996). "Differential interleukin-6 (IL-6) responses of three established myeloma cell lines in the presence of soluble human IL-6 receptors." Leukemia Research **20**(4): 291.

<http://www.sciencedirect.com/science/article/B6T98-3VXNHRT-2/2/2dd731b53de8a77a0a3e24ae6c9c4daf>

We investigated the possible influence of recombinant (r) sIL-6R on the growth of three IL-6 non-responsive or weakly IL-6 responsive long-term myeloma cell lines. The three cell lines chosen for the study (U266, L363 and Fravel) all expressed gp130 but differed in their expression of IL-6R and IL-6. mRNA analysis by northern blot and reverse transcriptase polymerase reaction showed that the cell line U266 was the only one that expressed IL-6 mRNA. Only U266 and L363 expressed IL-6R mRNA. 125I-rIL-6 binding studies and FACS analysis, using biotinylated IL-6 and antibodies directed against the IL-6R and gp130, showed corresponding results on the protein level. Addition of rIL-6R resulted in induction of IL-6 responsiveness in L363 cells, whereas the 3H-thymidine incorporation of the cell lines U266 and Fravel was unaffected by rIL-6R addition. In conclusion, the IL-6 unresponsive growth of several long-term myeloma cell lines in vitro can in some, but not all cases, be due to a deficiency in exogenous sIL-6R.

Dybkaer, K., B. Pedersen, et al. (2000). "Identification of acute myeloid leukemia patients with diminished expression of CD13 myeloid transcripts by competitive reverse transcription polymerase chain reaction (RT-PCR)." Leukemia Research **24**(6): 497.

<http://www.sciencedirect.com/science/article/B6T98-40378GB-7/2/5c0820c31098d0aaa34f5d17ff9fcc52>

Normal myeloid cells of monocytic and granulocytic origin express the metallopeptidase cluster of differentiation 13 (CD13) on the surface just as leukemic blasts in most acute myeloid leukemias (AML). A minor percentage of AML patients, however, lack the surface expression of CD13 antigen. To study this difference in CD13 surface expression, specific CD13 mRNA from 44 individuals were quantified by competitive reverse transcription polymerase chain reaction (RT-PCR). Absolute values for CD13 transcripts were normalised against glyceraldehyde-3-phosphate dehydrogenase (GAPDH) transcript levels to control for variations in sample preparation and mRNA degradation. By correlating normalised CD13 transcript levels and CD13 surface expression, a subgroup of AML patients was identified, having simultaneous diminished levels of myeloid CD13 transcripts and surface expression of the corresponding antigen. For this subgroup we suggest CD13/aminopeptidase N (APN) gene expression to be restricted primarily by limited amounts of transcripts. For the majority of AML patients determinants in addition to transcript levels must be involved in regulating CD13/APN gene expression.

Ek, S., E. Ortega, et al. (2005). "Transcriptional profiling and assessment of cell lines as in vitro models for mantle cell lymphoma." Leukemia Research **29**(2): 205.

<http://www.sciencedirect.com/science/article/B6T98-4D99K2T-2/2/d9c824d4e2e03f82ed7ca85bcba47afc>

Mantle cell lymphoma (MCL) is an aggressive malignancy and new treatment modalities must be established to increase patient survival time. In the search for new therapeutic targets, reliable and well-characterised in vitro models are essential. In this study, we have characterised three MCL cell lines (SP53, Granta 519 and NCEB1) in comparison with primary tumours from MCL, follicular lymphomas (FL), a FL cell line (RL), a Burkitt lymphoma cell line (RAJI) and five different B cell populations from healthy individuals. Expression profiling was used to determine the relative expression of >12000 transcripts in these samples, and flow cytometry analysis was performed to establish a phenotypic signature for each of the cell lines. In addition, the cell lines were sequenced, and the frequency of somatic mutations and immunoglobulin (Ig) variable heavy chain (VH) usage were determined. We show by hierarchical clustering that the cell lines retain a genetic signature similar to primary MCL, which readily separated the MCL samples from the other lymphoma cell lines and the FL tumours. Furthermore, the MCL cell lines showed differences in the frequency of VH somatic mutations (0-2.1%). The increased number of mutations in NCEB1, compared to the other MCL cell lines, was in agreement with a decreased expression of CD31, CD44, CXCR5, CCR7 and CCR6. Taken together, our data show that the cell lines are clearly derived from MCL tumours and expressed similar genetic and phenotypic signatures compared to primary tumours, which confirmed their usefulness as in vitro models.

Hanawa, H., T. Koike, et al. (1997). "Novel analysis of minimal residual disease in leukemia with TCR [beta] rearrangement--Detection of monoclonality by single strand conformation polymorphism and PCR using a clonotype primer of leukemic T cell receptor [beta]-chain RNA." Leukemia Research **21**(3): 201.

<http://www.sciencedirect.com/science/article/B6T98-3RGSWRB-J/2/c2ac4410559a3c8c2f9d738f43de5a26>

Several means of analyzing minimal residual disease (MRD) in leukemia involving the rearranged T cell receptor (TCR) gene have been described. We investigated MRD in leukemia with TCR [beta] rearrangement by examining TCR [beta]-chain RNA. A complementary DNA (cDNA) corresponding to the variable region of the TCR [beta]-chains originating from the peripheral blood or bone marrow from four patients was amplified. Single strand conformation polymorphism (SSCP) analysis of amplified cDNA showed that all four patients had monoclonal leukemia with TCR [beta] rearrangement; two patients had V[beta]2+ leukemia, another patient had V[beta]14+ leukemia and the other had V[beta]9+ leukemia. Flow cytometry supported this finding. Sequencing of the V[beta]2-complementarity determining region 3 (CDR3), V[beta]9-CDR3 and V[beta]14-CDR3 revealed monoclonality. To investigate MRD using TCR [beta]-chain RNA, cDNA from each patient was diluted with the cDNA of a healthy person and amplified using a specific CDR3 clonotype primer. A band in the ethidium bromide-stained agarose gel was detected from samples diluted 10 000-fold. SSCP analysis determined which V region gene was utilized in monoclonal leukemic cells. The leukemic cell specific TCR, determined in such a manner, may be a target for immunotherapy. Because the MRD of T cell malignancy can be easily examined once the CDR3 clonotype primer is made, this novel analysis is considered to be a useful method.

Harashima, A., Y. Matsuo, et al. "Transcription factor expression in B-cell precursor-leukemia cell lines: preferential expression of T-bet." Leukemia Research **In Press, Corrected Proof**
<http://www.sciencedirect.com/science/article/B6T98-4FJTP45-1/2/bf4ea7c12d7ce1ec4cb23a79293a70ca>

A number of transcription factors (TFs) have been reported that play crucial roles in hematopoiesis. However, only little is known about how these factors are involved in the mechanisms of hematopoietic development and lineage commitment. To investigate the roles of TFs in human B-cell precursors (BCPs), the present study analyzed the expression of the following 16 hematopoietic TFs: AML1, C/EBP[alpha], C/EBP[beta], C/EBP[gamma], C/EBP[epsilon], E2A, Ets-1, GATA-1, GATA-2, GATA-3, Ikaros, IRF-1, Pax5, PU.1, T-bet and TCF-1 in 30 human BCP-leukemia cell lines. All BCP-leukemia cell lines were found to be positive for the expression of AML1, C/EBP[gamma], E2A, Ets-1, IRF-1, Pax5 and PU.1 at the mRNA level. The mRNA expression of C/EBP[alpha], C/EBP[beta], C/EBP[epsilon], GATA-2, Ikaros, T-bet and TCF-1 was detected in 2 to 29 of the cell lines. Eight BCP-cell lines showed positivity for the dominant negative Ikaros isoform Ik6, while others were positive for expression of Ik1, 2, 3 and 4. GATA-1 and GATA-3 were universally negative. The expression of C/EBP[alpha], PU.1 and T-bet was positive at the protein level in five, 29 and four out of 30 BCP-cell lines, respectively. Cell lines were stimulated with interleukin (IL)-7 and/or interferon (IFN)-[gamma] to investigate the regulation of TF expression. T-bet was clearly induced in the two cell lines NALM-19 and NALM-29 after stimulation. C/EBP[beta] and IRF-1 were up-regulated in both cell lines and TCF-1 was down-regulated in NALM-19. No significant changes were observed for the other 12 TFs. The present report could provide useful information in the study of the role of TFs on normal and malignant human BCPs.

Horikoshi, T., H.-J. Lenz, et al. (1994). "Quantitative determination of the ratio of mutated to normal ras genes in the blood of leukemia patients by allele-specific PCR." Leukemia Research **18**(9): 693.

<http://www.sciencedirect.com/science/article/B6T98-4BP9WBF-MV/2/a7288214b97a21de39a5c77e2bed4b2d>

By combining allele-specific PCR amplification and a PCR-based quantitation approach, a method has been developed to estimate the mutated K-ras gene content in the blood of AML patients as a percentage of total K-ras. One PCR primer set was designed not to discriminate between mutant K-ras and wild-type K-ras and thus amplified the total K-ras gene. The other PCR primer set was designed to be allele-specific for K-ras genes containing a G to C mutation at codon 12. This primer set could discriminate the mutant and wild-type genes when the proportion of the mutated sequence was 0.2% of the total K-ras gene. To test the method on biological specimens, genomic DNA samples were analyzed from the peripheral blood of a patient who had secondary AML with the same codon 12 K-ras mutation. Two samples taken from this patient 2 months apart during follow-up had myeloblast cell contents of 67 and 80%. However, the percentage of mutated K-ras was 50% in both samples, suggesting that this patient may be inherently heterozygotic in this particular mutation. This ratio of mutated to normal K-ras in the patient's cells was confirmed by RNA-SSCP analysis and RNA sequencing. This quantitation method can provide a sensitive and specific estimation of the content of mutated K-ras alleles in patient samples.

Illmer, T., M. Schaich, et al. (1999). "A new PCR MIMIC strategy to quantify low *mdr1* mRNA levels in drug resistant cell lines and AML blast samples." Leukemia Research **23**(7): 653.

<http://www.sciencedirect.com/science/article/B6T98-3WM54SD-7/2/b6c8713c0156735b57abd18936a82790>

Determination of the MDR-phenotype in patients suffering from AML is an important hallmark of treatment outcome but is often complicated by technical problems in P-gp assessment. A PCR-MIMIC strategy was employed to construct PCR-fragments for a competitive and quantitative *mdr1* reverse transcription-PCR-assay. Using K562 cells, which had been selected for drug resistance to the epipodophyllotoxin VP16, a stepwise increase of *mdr1* levels depending on the concentration of VP 16 was shown with the MIMIC technique. Comparison of *mdr1* levels in drug selected K562 cells with the corresponding levels for P-gp and functional data indicated a mRNA threshold that has to be exceeded for the full expression of the MDR-phenotype. Subsequently *mdr1* levels of 34 samples of de novo acute myeloid leukemia were determined with the PCR-MIMIC strategy. Ten patient samples could be identified with elevated *mdr1* levels which were substantially lower than the levels observed in the MDR-cell line K 562 0.7 [μ]M VP16. Outcome analysis revealed that eight of the ten patients had an unfavourable prognosis and did not achieve CR after induction chemotherapy. Coexpression of *mdr1* and CD 34 was not associated with CR in all examined cases. Moreover all these patients had unfavourable cytogenetic aberrations. These data indicate a sensitive technique with applicability in patient material.

Jahn, B., L. Bergmann, et al. (1995). "Bone marrow-derived T-cell clones obtained from untreated acute myelocytic leukemia exhibit blast directed autologous cytotoxicity." *Leukemia Research* **19**(2): 73.

<http://www.sciencedirect.com/science/article/B6T98-3YB565M-3R/2/22f2fbee714bbc9d4d290d932ca16e54>

The eradication of minimal residual blast populations by activation of autologous cytotoxic cells with interleukin 2 (IL-2) is a new promising tool in the treatment of acute myelocytic leukemia (AML). However, the immunological effector cells are not yet clearly defined. The present study was designed to investigate the presence of cytotoxic precursor cells in active AML and to identify phenotypical and functional characteristics of autologous anti-leukemic cytotoxic effector cells. For this purpose, mononuclear cells (MNC) containing at least 70% leukemic blasts were isolated from bone marrow of untreated AML and cultured in the presence of 3000 IU/ml recombinant IL-2 (rIL-2) for 6-8 weeks. Under these conditions, T-cells were selected in the bone marrow cultures and overgrew the leukemic blasts. The resulting T-cell populations were cloned by limiting dilution and the clones obtained were characterized for their phenotypical and functional patterns. Totally, cloning resulted in 68 clones and a few cell lines. The clonality was verified by RT PCR analysis of TCR V[beta] gene expression. All clones obtained stained positive for CD2, CD3, DR and CD56. The vast majority (68%) of T-cell clones/lines was CD4+, a few clones expressed CD8 (19%) or CD4 and CD8, and four clones were of TCR[gamma][delta] origin. Seven of 15 clones tested, including three CD4+, two CD8+ and two TCR[gamma][delta]+-clones were found to be cytotoxic against autologous leukemic blast cells. All except one clone expressed oncolytic activities against allogeneic blasts too. One of the TCR[gamma][delta]+-clones demonstrated NK activity by lysis of K562 targets. The majority of the T-cell-clones released IL-2, IL-8, TNF-[alpha], GM-CSF but only a few IFN[gamma] and expressed high levels of mRNA for IL-2, TGF-[beta] and IL-10. None of the clones was found to produce IL-3, IL-4, IL-7 and TNF-[beta]. The data provide evidence of the existence of T-cell precursors in untreated AML bone marrow differentiating to cytotoxic cells with activity against autologous and allogeneic AML blast cells.

Jordan, J.-H., R. Fritsche-Polanz, et al. (2001). "A case of 'smouldering' mastocytosis with high mast cell burden, monoclonal myeloid cells, and C-KIT mutation Asp-816-Val." *Leukemia Research* **25**(7): 627.

<http://www.sciencedirect.com/science/article/B6T98-433NP9N-G/2/7cf951a8077be0a8f660f02ed4267058>

Mastocytosis is a term used for a group of disorders characterized by abnormal growth and accumulation of tissue mast cells (MC) in one or more organ systems. In patients with systemic mastocytosis (SM) the clinical course may be indolent or aggressive or even complicated by leukemic progression or an associated clonal hematologic non mast cell lineage disease (AHNMD). However, at first presentation (diagnosis) it may be difficult to define the category of disease and the prognosis. We report on a 48-year-old female patient with SM with urticaria pigmentosa-like skin lesions and mediator-related symptoms. She was found to have splenomegaly, a high infiltration grade (MC) in bone marrow biopsies (>30%), mild anemia, and a high serum tryptase level (>500 ng/ml). In addition, she exhibited discrete histologic signs of myeloproliferation in the 'non-affected' marrow and monoclonal blood cells established by C-KIT 2468A -> T mutation (Asp-816-Val) -analysis and HUMARA assay. Despite these findings, however, the clinical course was stable over years and no AHNMD or organ impairment developed. Because of the 'intermediate' clinical signs and absence of progression to aggressive disease, we proposed the term 'smouldering mastocytosis'.

Kawasaki, H., K. Shindou, et al. (1996). "Deoxycytidine kinase mRNA Levels in leukemia cells with competitive polymerase chain reaction assay." Leukemia Research **20**(8): 677.

<http://www.sciencedirect.com/science/article/B6T98-3W258FG-8/2/41d24b57616471a39726f20dae6ae01f>

Deoxycytidine kinase (dCyd kinase) is important for the phosphorylation of several different nucleoside antimetabolites. To understand the significance of dCyd kinase levels in chemotherapy, dCyd kinase mRNA levels were evaluated in several cells with a quantitative competitive polymerase chain reaction (PCR) assay. dCyd kinase catalytic activity and intracellular ara-CTP production were also compared with the levels of dCyd kinase mRNA. The assay was able to show: (i) that dCyd kinase catalytic activity and dCyd kinase mRNA levels were correlated in cells; (ii) that dCyd kinase mRNA levels were more sensitive in lower levels of 10 amol/[μg] of total RNA; and (iii) in cytosine arabinoside (ara-C)-resistant cells, both dCyd kinase mRNA levels and intracellular ara-CTP levels were lower compared with levels in sensitive cells. The PCR assay for dCyd kinase mRNA could be useful in the selection and monitoring of patients treated with nucleosides that are activated by this enzyme.

Kishino, K., K. Muroi, et al. (2002). "Evaluation of engraftment by ABO genotypic analysis of erythroid burst-forming units after bone marrow transplantation." Leukemia Research **26**(1): 13.

<http://www.sciencedirect.com/science/article/B6T98-44J720S-3/2/acfe39f022efd1b367dea2746722a0e5>

Six patients received an allogeneic bone marrow transplant from HLA-identical ABO-mismatched donors. ABO genotype of erythroid burst-forming units (BFU-E) from peripheral blood was analyzed using polymerase chain reaction with sequence specific primers (PCR-SSP). After bone marrow transplantation (BMT), engraftment of donor cells by ABO genotypic analysis of BFU-E was compared with ABO phenotypic analysis of red blood cells (RBCs). During the early stage after BMT, ABO genotype of BFU-E in the recipients converted to that of the donors. In contrast, mixed ABO phenotype of RBCs persisted for about 3 months. In one patient, autologous hemopoietic cell recovery was detected by the ABO genotypic analysis before clinical manifestation. ABO genotypic analysis of BFU-E is relevant for engraftment after ABO-mismatched BMT.

Koiso, H., N. Tsukamoto, et al. (2002). "Quantitative analysis of Cyclin D1 and CD23 expression in mantle cell lymphoma and B-chronic lymphocytic leukemia." Leukemia Research **26**(9): 809.

<http://www.sciencedirect.com/science/article/B6T98-458P438-2/2/2520d3c3099a04d5806a9a689400e4d9>

We studied Cyclin D1 (CyD1) and CD23 mRNA expression with real-time quantitative reverse transcription polymerase chain reaction (RQ-PCR) method. CyD1 expression in peripheral blood of seven mantle cell lymphoma (MCL) patients was found to be 1305.4 times higher than in 24 B-chronic lymphocytic leukemia (CLL) patients. CD23 expression in CLL was found to be 54.8 times higher than in MCL. These differences were statistically significant, and no overlap was found in CyD1 expression intensities between MCL and CLL. RQ-PCR allows rapid, simple and accurate quantification of CyD1 and CD23 expression, even from small samples, and is thus useful for the diagnosis of MCL and CLL.

Kristensen, T., H. K. Jensen, et al. (1994). "Overexpression of human thymidine kinase mRNA without corresponding enzymatic activity in patients with chronic lymphatic leukemia." Leukemia Research **18**(11): 861.

<http://www.sciencedirect.com/science/article/B6T98-4C118PD-T/2/d2befeeaa1057c3d44522c4688537835>

The level of cytosolic thymidine kinase (TK1) mRNA in lymphocytes from six healthy people and in lymphocytes from five patients with untreated chronic lymphatic leukemia (CLL) was determined with competitive polymerase chain reaction (competitive PCR). Using this procedure we have shown that in patients with CLL, there is an overexpression of TK1 mRNA without corresponding enzymatic activity. The TK1 mRNA level is approximately 100-fold higher in lymphocytes from CLL patients than in lymphocytes from healthy persons. A high level of TK1 mRNA without corresponding enzyme activity may indicate a defect in the processing of the enzyme. This may disturb the cells' normal feedback system and thereby influence the development of malignant conditions.

Min, Y. H., G. X. Li, et al. (2002). "Long-term bone marrow culture-derived stromal fibroblasts as a potential target for gene therapy in acute myelogenous leukemia." Leukemia Research **26**(4): 369.

<http://www.sciencedirect.com/science/article/B6T98-452RBCH-7/2/7d00300d5750cdaba78f48d78f718258>

As a part of our continuing efforts to develop gene therapy for acute myelogenous leukemia (AML), this study was undertaken to evaluate the possibility of using autologous bone marrow stromal fibroblasts (BMSFs) as a target cell population. Autologous BMSFs in AML were isolated from the stromal layers of long-term bone marrow culture (LTBMC) using immunomagnetic beads. BMSFs exhibited rapid proliferation even in the absence of growth factors. Cultures stimulated with bFGF produced significantly increased numbers of BMSFs than cultures without added growth factors. Using LNC/LacZ retroviral vector, the transduction efficiency of BMSFs was 13+/-4% at a 5 multiplicity of infection (MOI). LNC/interleukin-2 (IL-2)-transduced BMSFs produced between 1200 and 4800 pg of IL-2/106 cells per 24 h. Using adenoviral vector AdV/LacZ, the transduction efficiency was 84+/-10% at 100, and 92+/-8% at a MOI of 1000. Although the addition of basic fibroblast growth factor, epidermal growth factor, or platelet-derived growth factor did not affect the transduction efficiency, they increased the numbers of transduced

cells significantly (P6 cells per 24 h. Our finding that the genetically engineered autologous BMSFs of AML could be successfully established in vitro implies that BMSFs obtained from LTBMK might be considered as a target cell population for certain types of clinical gene therapy in AML.

Miyauchi, J., Y. Inatomi, et al. (1997). "The in vitro effects of all-trans-retinoic acid and hematopoietic growth factors on the clonal growth and self-renewal of blast stem cells in acute promyelocytic leukemia." Leukemia Research **21**(4): 285.

<http://www.sciencedirect.com/science/article/B6T98-3RGT92H-2/2/68fb30d0061f3dc42b5a8141be4b4e16>

All-trans-retinoic acid (ATRA) has been used as a potent therapeutic agent to induce differentiation of acute promyelocytic leukemia (APL) cells, and granulocyte colony-stimulating factor (G-CSF) has been reported to enhance this effect of ATRA in vitro. We investigated the effects of ATRA and three myeloid growth factors, including G-CSF, on the growth of the leukemic stem cells of 10 APL patients. G-CSF was the most powerful stimulator of leukemic colony formation in five out of 10 patients, but was neither the major stimulant of self-renewal of the blast stem cells nor an inducer of maturation. In contrast, ATRA was highly effective in inducing morphological maturation of leukemic promyelocytes, but variable results were obtained in regard to its effects on the growth of blast stem cells: ATRA suppressed both clonal growth and self-renewal in some patients, but was inactive or even had stimulating effects in the other patients. Similar variable effects were observed with the combination of ATRA and G-CSF. These findings indicate that the differentiation-inducing effect of ATRA is not always associated with growth inhibition of leukemic stem cells in vitro and justify the use of chemotherapy in conjunction with ATRA in the treatment of APL.

Nakagawa, Y., S. Yamaguchi, et al. (2004). "Differential expression of survivin in bone marrow cells from patients with acute lymphocytic leukemia and chronic lymphocytic leukemia." Leukemia Research **28**(5): 487.

<http://www.sciencedirect.com/science/article/B6T98-4B5JM6V-6/2/1136f69233c135c369191fdbcb166f915>

Survivin, a member of the inhibitor of apoptosis protein (IAP) gene family, has been detected widely in fetal tissue and in a variety of human malignancies. In the current study, we investigated the expression of IAP family proteins in bone marrow samples from acute lymphocytic leukemia (ALL), chronic lymphocytic leukemia (CLL) and control cases by quantitative real-time RT-PCR method and an immunohistochemical approach. Overexpression of survivin and cIAP2 mRNA was significant in CLL bone marrow cells ($P < 0.05$, respectively) compared with control samples. By immunohistochemistry, survivin was detected in a few scattered myeloid cells in all cases of control bone marrow. Concerning the ALL bone marrow, more than half the cases demonstrated positive expression of survivin (8 out of 13), while the majority of CLL cases (20 out of 21) exhibited intense expression of survivin. The differential subcellular localization of survivin was distinct between ALL and CLL cases. ALL cells essentially revealed nuclear localization of survivin as well as cytoplasmic signals in some cases, while CLL cells from the majority of cases predominantly showed cytoplasmic expression. Next, RT-PCR was performed for the expression of survivin and its splicing variant, survivin-2B and survivin- Δ Ex3 in ALL and CLL cells, as the distribution of these variants would be regulated by nuclear/cytoplasmic transport system. In both ALL and CLL bone marrow samples, the expression of wild-type survivin was more predominant than that of survivin-2B or survivin- Δ Ex3, although the expression of survivin- Δ Ex3 was prominent in samples from survivin-expressing ALL cases. Thus, the splicing of

survivin mRNA may be differently regulated in ALL and CLL cells, causing distinct manners of nuclear/cytoplasmic transport of survivin protein. In conclusion, our observations indicate a differential regulatory mechanism for the expression of IAP family proteins in ALL and CLL cells, although the functions of IAP families and the mechanisms of nuclear/cytoplasmic transport of survivin should be clarified in future studies.

Niemeyer, P., O. Tureci, et al. (2003). "Expression of serologically identified tumor antigens in acute leukemias." Leukemia Research **27**(7): 655.

<http://www.sciencedirect.com/science/article/B6T98-47K2J0N-2/2/4311d691880f917ee6e25676eef094f0>

Cancer/testis antigens (CTA) are an expanding family of immunogenic proteins selectively expressed in human neoplasms. As little is known about the expression of serologically identified CTA in leukemias so far, we investigated the expression of 5 CT genes (SSX-1, HOM-MEL-40/SSX-2, HOM-TES-14/SCP-1, SCP-3 and NY-ESO-1) in leukemic blood samples obtained from patients with either acute lymphatic leukemias (ALL) or myelocytic leukemia (AML). RT-PCR-analyses showed no expression of any of the CT-genes in the leukemia samples of 19 patients with AML, whereas frequent expression was found in ALL. In the 17 ALL cases studied, SCP3a, SSX-1, HOM-MEL-40/SXX-2 and HOM-TES-14/SCP-1 were expressed in 47, 29, 29 and 12%, respectively, whereas no case was positive for NY-ESO-1. 65% of patients with ALL showed expression of at least one, 41% of two or more of the five CT-genes investigated. We conclude that a majority of the ALLs might be amenable for specific immunotherapeutic interventions. However, the identification of additional antigens with a frequent expression in leukemias is warranted to allow the development of widely applicable polyvalent leukemia vaccines.

Pallis, M., C. Seedhouse, et al. (2003). "Flow cytometric measurement of phosphorylated STAT5 in AML: lack of specific association with FLT3 internal tandem duplications." Leukemia Research **27**(9): 803.

<http://www.sciencedirect.com/science/article/B6T98-47YH3V0-7/2/0c199dfb3517c8bcc8105056d0971133>

STAT5 phosphorylation has been noted in 69-95% of AML cases by Western blotting. We used flow cytometry to measure phosphorylated STAT5 on a semi-quantitative scale. The method was validated on K562 cells, which constitutively express phosphorylated STAT5, but lose this when BCR-abl tyrosine kinase activity is blocked by STI571. Phosphorylated STAT5 was found to measure 2.22 ± 0.09 relative fluorescence units (RFU) falling to 0.925 ± 0.005 RFU in the presence of STI571. Phosphorylated STAT5 expression was 0.99 to 2.09 RFU in 28 primary AML samples. There was no logical cut-off point between positive and negative fluorescence. FLT3 internal tandem duplications, found in 11/28 samples, were not significantly associated with the level of phosphorylated STAT5 expression. We conclude that STAT5 phosphorylation can be measured sensitively by flow cytometry in AML and that its expression should not be dichotomised as present or absent.

Perkel, J. M., M. C. Simon, et al. (2002). "Identification of a c-myc attenuator-binding factor." Leukemia Research **26**(2): 179.

<http://www.sciencedirect.com/science/article/B6T98-44PK59K-7/2/fee056022186d26f0c890ae0e894629a>

Expression of the c-myb proto-oncogene is developmentally regulated at the level of transcription elongation. In pre-B cells, complete c-myb transcripts are produced, whereas transcripts are attenuated near or within a 300-base pair (bp) interval of the first c-myb intron in mature cells. Hypothesizing that transcription attenuation results from a protein complex that physically impedes the progress of RNA polymerase II through the intron, we used electrophoretic mobility shift assays (EMSA) to search for DNA-binding activities that correlated with downregulation of c-myb transcription. We identified a stage-specific DNA binding activity, termed ABF, present in mature B cells but not in pre-B cells. ABF binds to a 15-bp DNA element located within a 300-bp BstEII-XbaI fragment. DMSO-treatment of murine erythroleukemia cells results in rapid downregulation of c-myb transcription and upregulation of ABF DNA binding activity. Thus, ABF binding activity correlates with downregulation of c-myb transcription in two systems. Preliminary biochemical characterization of ABF from mature B cells demonstrates that its primary DNA-binding component is a 64-kDa-protein. We hypothesize that this factor may represent a member of the transcriptional attenuation complex.

Scott, S., T. Kimura, et al. (2003). "Microsatellite mutations of transforming growth factor-[beta] receptor type II and caspase-5 occur in human precursor T-cell lymphoblastic lymphomas/leukemias in vivo but are not associated with hMSH2 or hMLH1 promoter methylation." Leukemia Research **27**(1): 23.

<http://www.sciencedirect.com/science/article/B6T98-460WG9P-1/2/5a29859452a0816e29dd5c0a99988491>

In solid cancers, defective DNA mismatch repair (MMR) is most commonly caused by hMSH2 or hMLH1 mutations, or epigenetic silencing of hMLH1 by promoter hypermethylation, and results in the acquisition of characteristic frameshift microsatellite mutations of mononucleotide repeats located within the coding regions of defined target genes. We previously identified hMSH2 mutations in T-cell lymphoblastic lymphoma (T-LBL) patient tumor samples and others have reported coding region microsatellite mutations in T-cell acute lymphoblastic leukemia (T-ALL) cell lines. Thus, while MMR gene mutations are known to occur in some human T-lymphoblastic tumors in vivo, it is still unknown if the coding region microsatellite mutations detected in human cell lines also occur in vivo or if hMLH1 or hMSH2 promoter hypermethylation contributes to defective MMR in these tumors. We analyzed the TGF[beta]RII (A)10 and caspase-5 (A)10 coding region repeats in 16 human T-LBL/ALL patient tumor samples and identified six with microsatellite mutations in one or both repeats. There was no evidence of hMSH2 or hMLH1 promoter methylation as assessed by standard methylation specific PCR or by a novel temporal temperature gradient electrophoresis (TTGE) method that analyzed 25 and 30 CpG sites in the hMLH1 and hMSH2 promoters, respectively. Our results indicate that coding region microsatellite mutations characteristic of defective MMR occur in some human T-LBL/ALL in vivo but not as a consequence of hMLH1 or hMSH2 promoter hypermethylation. Furthermore, the identification of TGF[beta]RII and caspase-5 coding region mutations in vivo implicates these genes in the pathogenesis of human T-LBL/ALL.

Sotlar, K., C. Fridrich, et al. (2002). "Detection of c-kit point mutation Asp-816 -> Val in microdissected pooled single mast cells and leukemic cells in a patient with systemic mastocytosis and concomitant chronic myelomonocytic leukemia." Leukemia Research **26**(11): 979.

<http://www.sciencedirect.com/science/article/B6T98-45JPFS6-2/2/15310005c90f62c646ffb6a8e9040709>

The c-kit mutation Asp-816->Val is detectable not only in neoplastic mast cells (MCs) in patients with systemic mastocytosis (SM) but also in most associated hematologic non-MC lineage disease (AHNMD). In order to prove a monoclonal disease evolution we investigated DNA of pooled microdissected single cells for the presence of the mutation in a patient with SM and concomitant chronic myelomonocytic leukemia (CMML). LightCycler melting curve analysis and direct sequencing of nested polymerase chain reaction (PCR) products revealed the c-kit mutation in tryptase-positive MC and in leukemic CD15-positive cells in bone marrow infiltrates, but not in colonic epithelial cells, thus, suggesting a monoclonal evolution of SM and concurrent CMML on the basis of a somatic mutation in a common hematologic progenitor.

Stacchini, A., M. Aragno, et al. (1999). "MEC1 and MEC2: two new cell lines derived from B-chronic lymphocytic leukaemia in prolymphocytoid transformation." Leukemia Research **23**(2): 127.

<http://www.sciencedirect.com/science/article/B6T98-3VWP0J1-10/2/f36f4b109d79d2e8544506a86ea45e4e>

We report the establishment and characterization of two cell lines, MEC1 and MEC2, that grew spontaneously on two subsequent occasions from the peripheral blood (PB) of a patient with B-chronic lymphocytic leukemia (B-CLL) in prolymphocytoid transformation. The patient was EBV-seropositive, his leukemic cells were EBNA negative, but the spontaneously grown cell lines are EBNA-2 positive. In liquid culture MEC1 cells grow adherent to the vessel wall and as tiny clumps; MEC2 cells do not adhere and form large clumps. The doubling time of MEC1 is 40h and of MEC2 is 31h. Both cell lines express the same light ([kappa]) and heavy chains ([mu], [delta]) as the fresh parental B-CLL cells at the same high intensity, share the expression of mature B cell markers (CD19, CD20, CD21, CD22), differ in the expression of CD23 and FMC7, are CD11a+, CD18+, CD44+, CD49d+, CD54+ and express at high levels both CD80 and CD86. CD5 is negative on MEC1 cells (as on the vast majority of parental cells) and it has been lost by MEC2 cells after several months of culture. The cells have a complex karyotype. The tumour origin of MEC1 and MEC2 has been demonstrated by Southern blot analysis of the IgH loci and by Ig gene DNA sequencing. They use the VH4 Ig family and have not undergone somatic mutations (94.8% homology with germline Ig gene 4-59). Cytofluorographic analysis and RT-PCR reveal that MEC1 and MEC2 overexpress Bcl-2 together with Bax, express large amounts of Bcl-xL and trace amounts of Bcl-xS.

Toba, K., H. Hanawa, et al. (2003). "Fc[epsilon]R1 and CD22 mRNA are expressed in early B-lineage and myeloid leukemia cell lines." Leukemia Research **27**(2): 173.

<http://www.sciencedirect.com/science/article/B6T98-461XG0N-4/2/dab009b9623e60e262c6385c8f94042f>

CD22, one of the important markers for diagnosing B-lineage acute leukemia, was expressed in mature basophil granulocytes. We then investigated the expression of CD22 and other B cell- and basophil-related molecules in 25 human acute leukemia cell lines to find the phenotype of the virtual common progenitor of B and myeloid lineage. Surface and cytoplasmic expressions of antigens were analyzed using a flow cytometer and an essential antibody panel used for diagnosing acute leukemia as well as cytokine receptors and basophil-related enzymes. Messenger RNA expression of Fc[epsilon]R1 and CD22 was also analyzed. Peroxidase-positive and -negative myeloid leukemias showed eosinophil- and basophil-type expression of enzymes, respectively. Early myeloid and B-lineage cells expressed basically similar combinations of cytokine receptors and various combinations of mRNA listed above, while T-lineage cells did not. The virtual common progenitor of B and myeloid lineage cells may be defined as immature cells simultaneously expressing B and basophil phenotypes.

Tokura, Y., M. Shikami, et al. (2002). "Augmented expression of P-gp/multi-drug resistance gene by all-trans retinoic acid in monocytic leukemic cells." Leukemia Research **26**(1): 29.

<http://www.sciencedirect.com/science/article/B6T98-44J720S-5/2/b4e49ab605ef5bc6cf990a9619272c2e>

P-glycoprotein (P-gp)/multi-drug resistance 1 (MDR1) gene is recognized to be, at least in part, responsible for the refractoriness to chemotherapy of leukemia. The transcriptional mechanism of MDR1 gene is largely unknown. However, recent reports have clarified that early growth response 1 gene (Egr1) positively regulates MDR1 transcription, while Wilms' tumor suppressor gene (WT1) does negative regulation of MDR1 gene expression in 12-O-tetradecanoylphorbol-13-acetate treated K562 cells. In addition, Egr1 and WT1 are structurally related transcription factors and bind to quite similar DNA sequences. Our study of mRNA expression profile of Egr1, WT1 and MDR1 in fresh AML samples demonstrated that there are disease-specific patterns. Egr1 mRNA was frequently and strongly expressed in monocytic leukemia cells, especially in AML M4 cells. WT1 mRNA was undetectable in t(8;21) AML cells. mRNA expression of MDR1 was frequent in AML M1 and t(8;21) AML cells, in which the expression level was highest in AML M1 and was low in monocytic leukemia (M4 and M5). Then, expression level of MDR1 was inversely correlated with Egr1. By liquid culture of leukemia cell lines and fresh AML cells with the addition of all-trans retinoic acid (ATRA), modulation of P-gp/MDR1 and Egr1 was observed and the pattern of modulation was divided into four groups: (1) blastic AML type, in which distinct expression of P-gp/MDR1 and CD34 was not influenced by ATRA; (2) t(8;21)AML type, in which P-gp/MDR1 expression was augmented by ATRA, while CD34 was kept high; (3) AML M3 type, in which P-gp/MDR1 expression was reduced with granulocytic differentiation by ATRA; (4) monocytic AML type, in which P-gp/MDR1 expression was augmented by ATRA, while CD34 expression decreased, and strong Egr1 expression was downregulated just prior to the augmentation of P-gp/MDR1 expression. WT1 expression was not influenced by the addition of ATRA in each group. Previous reports have suggested that P-gp/MDR1 plays an important role in resistance to chemotherapy, and is recognized as one of the stem cell marker. However, P-gp/MDR1 expression augmented by ATRA, which was observed in monocytic AML, was recognized as a functional molecule of mature monocyte/macrophage, because CD34 expression decreased and CD13 expression increased by ATRA. Finally, expression of P-gp/MDR1 in monocytic leukemia, which was functionally confirmed by Rh123 efflux study, was thought to be closely related to the characteristic modulation of Egr1 expression by ATRA.

Ullmannova, V., P. Stockbauer, et al. (2003). "Relationship between cyclin D1 and p21Waf1/Cip1 during differentiation of human myeloid leukemia cell lines." Leukemia Research **27**(12): 1115.

<http://www.sciencedirect.com/science/article/B6T98-48XCCH3-2/2/a9f4ee6a1ed1b17866109baea76c4e75>

Expression of cell cycle-regulating genes was studied in human myeloid leukemia cell lines ML-1, ML-2 and ML-3 during induction of differentiation in vitro. Myelomonocytic differentiation was induced by phorbol ester (12-o-Tetradecanoyl-phorbol-13-acetate, TPA), tumor necrosis factor [alpha] (TNF[alpha]) or interferon [gamma] (INF[gamma]), or their combination. Differentiation (with the exception of TNF[alpha] alone) was accompanied by inhibition of DNA synthesis and cell cycle arrest. Inhibition of proliferation was associated with a decrease in the expression of cdc25A and cdc25B, cdk6 and Ki-67 genes, and with increased p21Waf1/Cip1 gene expression, as measured by comparative RT-PCR. Expression of the following genes was not changed after induction of differentiation: cyclin A1, cyclin D3, cyclin E1 and p27Kip1. Surprisingly, cyclin D1 expression was upregulated after induction by TPA, TNF[alpha] with INF[gamma] or BA. Cyclin D2 was upregulated only after induction by BA. The results of the expression of the tested genes

obtained by comparative RT-PCR were confirmed by quantitative real-time (RQ) RT-PCR and Western blotting. Quantitative RT-PCR showed as much as a 288-fold increase of cyclin D1 specific mRNA after a 24 h induction by TPA. The upregulation of cyclin D1 in differentiating cells seems to be compensated by the upregulation of p21Waf1/Cip1. These results, besides others, point to a strong correlation between the expression of cyclin D1 and p21Waf1/Cip1 on the one hand and differentiation on the other hand in human myeloid leukemic cells and reflect a rather complicated network regulating proliferation and differentiation of leukemic cells.

Verstovsek, S., F. J. Giles, et al. (2004). "Telomerase activity is not a prognostic factor in chronic lymphocytic leukemia." Leukemia Research **28**(7): 707.

<http://www.sciencedirect.com/science/article/B6T98-4CC7RWX-1/2/1a9d7b04f3f19635cab58b22d4959038>

We measured telomerase activity (TA) in bone marrow samples from 214 patients with CLL and correlated it with patients' characteristics and survival. In >50% of cases (126/214; 59%) no detectable TA was found. There was no difference in TA between previously treated (n=153) and untreated (n=61) patients (P=0.4), or patients with various Rai (0-IV) stages (P=0.85). TA correlated significantly with white blood cell and lymphocyte count (P=0.02 and 0.01, respectively) but not with bone marrow cellularity, [beta]2-microglobulin ([beta]2M), or other patient characteristics. Patients who had no TA had slightly lower [beta]2M and lower lymphocyte counts (P=0.5 and 0.04, respectively) as compared with patients with detectable TA. However, there was no correlation between TA and survival. This data suggests that TA may not play a significant role in the clinical behavior of CLL.

Wan, M., J. Chow, et al. (2004). "Allelotyping of gastrointestinal nasal-type NK/T-cell lymphoma." Leukemia Research **28**(4): 339.

<http://www.sciencedirect.com/science/article/B6T98-49J8T38-3/2/f236d83bc38692b07017a31131c66cf1>

Nasal-type natural killer/T-cell lymphoma (NKL) is a rare but distinct malignancy that often involves the mid-facial region and the gastrointestinal tract. This study is the first genome-wide allelotyping analysis on this rare lymphoma. We applied 382 microsatellite markers covering loci which spanned 22 autosomes to screen for allelic imbalances (AI) in six intestinal NKL. The most common chromosomal regions of allelic imbalances were found in 11p, 9q and 13q. Novel spots of allelic losses were found at 2p21, 2q37.22, 18p11.21 and 18q12.1. In spite of presence of a few recurrent loci of imbalances, the allelotyping results show that NKL is heterogeneous.

Wang, J. C. and C. Chen (1998). "N-RAS oncogene mutations in patients with agnogenic myeloid metaplasia in leukemic transformation." Leukemia Research **22**(7): 639.

<http://www.sciencedirect.com/science/article/B6T98-3V4JR3R-R/2/d4bee82a0c748588b745e316a3062f8f>

From 5% to 20% of patients with agnogenic myeloid metaplasia (AMM) will evolve into a terminal leukemic phase; N-RAS gene mutations are the most common gene abnormalities detected in patients with leukemia. The present study was designed to see if N-RAS gene mutations are associated with the leukemic transformation in AMM. Over a 9 year period, in a single institution,

43 patients with AMM were studied. Of these, ten patients were found to be in leukemic phase. The results showed that none of the patients in chronic phase (40 patients) had N-RAS gene mutations, while two patients in leukemic phase showed this gene mutation. One patient was found to have a codon 12 mutation with arginine substituting for glycine (GGT->CGT); the other was a codon 12 mutation with glutamine substituting for glycine (GGT->GAT). The present study suggests that N-RAS mutations are rare events in the chronic phase of AMM, and are only occasionally found when patients have evolved into leukemic transformation. Further studies to search for other gene abnormalities in AMM may be warranted.

Wu, S., A. Korte, et al. (2005). "Interaction of bone marrow stromal cells with lymphoblasts and effects of prednisolone on cytokine expression." Leukemia Research **29**(1): 63.

<http://www.sciencedirect.com/science/article/B6T98-4D48XF7-1/2/17a581d689f0dea6e71df5c0b4a167c9>

Cytokines play a key role in the differentiation, growth and survival of hematopoietic cells in the bone marrow (BM) stroma microenvironment. The mechanisms by which stromal derangements may contribute to the evolution of hematopoietic neoplasias are largely unknown. Here, we characterized BM stromal cells isolated from children with acute lymphoblastic leukemia and determined the effect of the interaction between stromal cells and lymphoblasts on cytokine expression as well as the effect of prednisolone using mono- and co-culture models. The analyses demonstrate that (1) stromal cells and lymphoblasts display different patterns of cytokine gene expression individually. (2) Stromal cells influence gene expression of cytokines in lymphoblasts and vice versa. (3) Glucocorticoid substitution inhibit cytokine gene expression in stromal cells. These findings indicate that stromal cells are important components involved in malignant hematopoiesis and also in response to therapy.

Yamamoto, K., S. Abe, et al. (2004). "Expression of IAP family proteins in myelodysplastic syndromes transforming to overt leukemia." Leukemia Research **28**(11): 1203.

<http://www.sciencedirect.com/science/article/B6T98-4CJV8YV-7/2/e2860d193f75b9263669da1ab8a92086>

Bone marrow cells of patients with myelodysplastic syndromes (MDS) frequently undergo apoptosis, though the apoptotic cell ratio decreases when overt leukemia (OL) develops. Thus, we compared the expression of the inhibitor of apoptosis protein (IAP) gene family proteins in bone marrow samples from control, MDS, OL transformed from MDS (MDS -> OL), and de novo acute myelogenous leukemia (AML) subjects by the quantitative real-time RT-PCR method and an immunohistochemical approach. Overexpression of mRNA for survivin, cIAP1, NAIP and XIAP was significant in MDS bone marrow cells compared with control samples. However, the expression of mRNA for survivin, cIAP1 and cIAP2 exhibited a remarkable decrease after the development of OL (MDS -> OL). By immunohistochemistry, survivin was found to localize to the nucleus of myeloid cells in the majority of MDS cases. Next, the chronological changes in the expression of IAPs were determined in cases of MDS with evolution of OL. Although the expression of cIAP1 and cIAP2 revealed a sudden or gradual decrease as OL developed, survivin in many cases and XIAP in the majority of cases exhibited a peak of expression before a decline, indicating that these IAPs could be associated with the early events in the development of OL.

Yashima, A., C. Maesawa, et al. (2003). "Quantitative assessment of contaminating tumor cells in autologous peripheral blood stem cells of B-cell non-Hodgkin lymphomas using immunoglobulin heavy chain gene allele-specific oligonucleotide real-time quantitative-polymerase chain reaction." Leukemia Research **27**(10): 925.

<http://www.sciencedirect.com/science/article/B6T98-48JC9WM-2/2/d4faba8ea800b8eb0154204cdbcdf87c>

A real-time quantitative-polymerase chain reaction (RQ-PCR) targeting the immunoglobulin heavy chain (IgH) gene has been used for the quantification of minimal residual disease (MRD) in B-cell hematological malignancies. In non-Hodgkin lymphoma (NHL), experimental costs are increased, as a large number of primer-probe sets are required because of diversity, due to somatic and ongoing mutations of the IgH gene. We developed an allele-specific oligonucleotide (ASO) combined with a germline consensus probe-based RQ-PCR assay and examined MRD in peripheral blood stem cells (PBSC). The IgH consensus probes were adapted in seven (50%) of 14 amplifiable cases. Patients with heavily contaminating tumor cells in PBSC relapsed after PBSC transplantation. Our strategy will contribute to the development of a cost-efficient, precisely quantitative and systemic detection assay for MRD in NHL.

Yokohama, A., M. Karasawa, et al. (2001). "Molecular detection of tumor cells at diagnosis invading the bone marrow and peripheral blood of patients with aggressive or indolent lymphomas." Leukemia Research **25**(9): 749.

<http://www.sciencedirect.com/science/article/B6T98-4599B2H-3/2/a15755c7fc0c884b564b67fcd7c90479>

We studied tumor cell invasions of bone marrow and peripheral blood in patients with various types of advanced non-Hodgkin's lymphoma by amplifying complementarity determining region III using the polymerase chain reaction (PCR) method and developing patient-specific probes. After molecular engineering, we could detect tumor cells in bone marrow from seven of 11 cases and in peripheral blood from six of 11 cases, despite negative results in four cases studied morphologically. Indolent cases were more likely to yield positive results than aggressive cases. The reason may be different biological behaviors among the histological types.

Zhou, R., M. Frostvik Stolt, et al. (2002). "Real-time RT-PCR for the determination of topoisomerase II mRNA level in leukaemic cells." Leukemia Research **26**(5): 487.

<http://www.sciencedirect.com/science/article/B6T98-45CX73K-D/2/628b2ca821241d47ba9852010e2a9eb6>

We developed a real-time RT-PCR assay for the quantification of topoisomerase II (topo II) mRNA level. It was applied on peripheral leukaemic cells from 23 patients with acute myelogenous leukaemia (AML) and 23 with chronic lymphocytic leukaemia (CLL). RNA template dilutions from 0.25 to 25 ng per reaction were used as standard curves for topo II[alpha], [beta] and the internal control 18S rRNA. About 57% (26/46) and 26% (12/46) of the specimens had detectable topo II[beta] and [alpha] mRNA, respectively. The correlation between these two factors was $r=0.7$ and $P=0.0001$. No relationship between topo II[alpha] or [beta] mRNA level and response to chemotherapy was found in AML patients ($n=19$ assessable for response). Our method is rapid and convenient for quantification of topo II[alpha] and [beta] mRNA levels, and could be suitable for investigation in a larger population.

Bogdarina, I., H. C. Murphy, et al. (2004). "Investigation of the role of epigenetic modification of the rat glucokinase gene in fetal programming." Life Sciences **74**(11): 1407.

<http://www.sciencedirect.com/science/article/B6T99-4B42FPW-4/2/a9308159457ab5a29ef64848d6018514>

Fetal malnutrition is associated with development of impaired glucose tolerance, diabetes and hypertension in later life in humans and several mammalian species. The mechanisms that underlie this phenomenon of fetal programming are unknown. We hypothesize that adverse effects in utero and early life may influence the basal expression levels of certain genes such that they are re-set with long-term consequences for the organism. An excellent candidate mechanism for this re-setting process is DNA methylation, since post-natal methylation patterns are largely established in utero. We have sought to test this hypothesis by investigating the glucokinase gene (Gck) in rat offspring programmed using a maternal low protein diet model (MLP). Northern blot reveals that fasting levels of Gck expression are reduced after programming, although this distinction disappears after feeding. Bisulphite sequencing of the hepatic Gck promoter indicates a complete absence of methylation at the 12 CpG sites studied in controls and MLP animals. Non-expressing cardiac tissue also showed no DNA methylation in this region, whereas brain and all fetal tissues were fully methylated. These findings are not consistent with the hypothesis that programming results from differential methylation of Gck. However, it remains possible that programming may influence methylation patterns in Gck at a distance from the promoter, or in genes encoding factors that regulate basal Gck expression.

Caronti, B., C. Calderaro, et al. (1998). "Dopamine receptor mRNAs in the rat lymphocytes." Life Sciences **62**(21): 1919.

<http://www.sciencedirect.com/science/article/B6T99-3T0TY5N-2/2/20f3c6d6de1728310fc1466e4fcd090e>

It has been suggested that dopamine might play a role in the regulation of the immune system. In this study, reverse transcriptase-polymerase chain reaction (RT-PCR) was used to investigate the expression of mRNA for the different subtypes of dopamine receptors in the rat lymphocytes. D1, D3 and D5 receptor mRNAs were identified. These results provide further evidence for the interaction of dopamine systems and the immune system, and suggest to further investigate whether the immunosuppressive actions of dopamine and dopaminergic drugs might depend on a direct interaction with dopamine receptors on the lymphocyte membrane. Moreover, they suggest the suitability of this animal species to further investigate the correlation between changes in the expression of central and peripheral dopamine receptors produced by manipulations of the dopamine systems.

Chang, S. L., J. Bersig, et al. (2000). "Chronic cocaine alters hemodynamics and leukocyte-endothelial interactions in rat mesenteric venules." Life Sciences **66**(24): 2357.

<http://www.sciencedirect.com/science/article/B6T99-40B7XB5-5/2/0e750bce2094b175774c2b5a74ca74aa>

We investigated the effects of chronic cocaine exposure on the microcirculation in the rat mesenteric venules under both non-inflammatory and FMLP-induced inflammatory conditions. Chronic cocaine significantly increased WBC rolling flux in both conditions, and potentiated FMLP-induced leukocyte-endothelial cell adhesion (LEA). In cocaine-treated animals, total WBC number increased by 91%, and the ratio of white blood cell to red blood cell velocity was significantly lower, while vessel diameter was unchanged. Chronic cocaine decreased serum levels of tumor necrosis factor alpha (TNF-[alpha]) and interleukin-6 (IL-6), but had no effect on interleukin-1 beta (IL-1[beta]). Expression of intercellular adhesion molecule-1 (ICAM-1) was increased in mesenteric venules following chronic cocaine exposure, and may be one of the mechanisms underlying enhancement of FMLP-induced LEA. The increase in WBC count, WBC flux and LEA, and the change in cell velocity seen in the cocaine-treated animals could cause a decrease in effective vessel diameter and a change in intravascular resistance, and may underlie the progressive vascular damage seen in chronic cocaine-abusing individuals.

Cushing, D. J., M. Baez, et al. (1994). "Serotonin-induced contraction in canine coronary artery and saphenous vein: Role of a 5-HT_{1D}-like receptor." *Life Sciences* **54**(22): 1671.

<http://www.sciencedirect.com/science/article/B6T99-4751TMH-2NR/2/e8c4e22c9af4e5021bce604d3757f5d3>

The identity of the serotonin (5-HT) receptor(s) that mediate(s) contraction in canine coronary artery and saphenous vein remains controversial. Ring segments of endothelium-denuded coronary artery and helical strips of saphenous vein were suspended in organ chambers for measurement of isometric force. 5-HT, [alpha]Me-5-HT and sumatriptan contracted both coronary artery and saphenous vein and the non-selective 5-HT receptor antagonist 1-naphthylpiperazine (100nM) blocked 5-HT- and sumatriptan-induced contraction in both tissues. The agonist rank order potency for contraction (5-HT>sumatriptan>[alpha]Me-5-HT>5-MeOT>5-MeT) was similar in both tissues and was consistent with that for a 5-HT_{1D} receptor. Oligonucleotide primers specific for the 5-HT_{1D} receptor sequence were designed for use in a polymerase chain reaction (PCR). cDNA derived from total RNA or mRNA from canine tissues was used in the PCR. PCR resulted in the amplification of a 632 base pair sequence in both canine coronary artery and saphenous vein; consistent with that expected for the 5-HT_{1D} receptor. Southern blot analysis, with an oligonucleotide probe internal to the sequence amplified by the PCR primers, confirmed that the sequence amplified by PCR was the 5-HT_{1D} receptor. Thus, the 5-HT_{1D} receptor is expressed in canine coronary artery and saphenous vein and taken together with the pharmacological data, supports the possibility that a 5-HT_{1D}-like receptor mediates contraction in these two tissues.

Farooqui, S. M. (1994). "Induction of adenylate cyclase sensitive dopamine D₂-receptors in retinoic acid induced differentiated human neuroblastoma SHSY-5Y cells." *Life Sciences* **55**(24): 1887.

<http://www.sciencedirect.com/science/article/B6T99-4754KHC-2/2/cdd8ff78ab5e53087ad8ea0f96dcfc3d>

Dopamine D₂ receptor (D₂-receptor) expression and its coupling to Gi sensitive adenylate cyclase was investigated in human neuroblastoma SHSY-5Y cells. Incubation of SHSY-5Y cells in the presence of 100 nM retinoic acid (RA) for 24 hours resulted in phenotypic differentiation accompanied by a 47% increase in D₂-receptor mRNA and a significant increase in the specific binding of a D₂-receptor antagonist, [³H]YM09151-2. Stimulation of D₂-receptors in differentiated

cells by LY171-555, a D2-agonist, attenuated cellular cAMP levels by 30%. The effect of LY171-555 on cAMP levels was blocked by the D2-antagonist, (-)-sulpride. Application of these drugs to control undifferentiated cells or differentiated cells incubated with vehicle only had no effect on cellular cAMP levels. These studies suggest that differentiated SHSY-5Y cells express functional D2-receptors and will provide a useful model for future studies on the regulation of expression and function of D2-receptors in cellular differentiation of neuronal cells.

Fujii, T., T. Okuda, et al. (2003). "Detection of the high-affinity choline transporter in the MOLT-3 human leukemic T-cell line." *Life Sciences* **72**(18-19): 2131.

<http://www.sciencedirect.com/science/article/B6T99-47X0WMJ-1/2/bd4a23563cf1c232fb845e187c9bc057>

We previously showed that lymphocytes possess the necessary components to constitute an independent, non-neuronal cholinergic system; these include acetylcholine (ACh) itself, choline acetyltransferase (the ACh-synthesizing enzyme), and both muscarinic and nicotinic ACh receptors (AChRs). In addition, we showed that stimulation of AChRs with their respective agonists elicits a variety of biochemical and functional effects, suggesting that lymphocytic cholinergic system is involved in the regulation of immune function. In nerve terminals, choline taken up via the high-affinity choline transporter (CHT1) is exclusively utilized for ACh synthesis. In the present study, therefore, we investigated the expression of CHT1 in T-lymphocytes. Reverse transcription-polymerase chain reaction analysis revealed that MOLT-3 cells, a human leukemic T-cell line used as a T-lymphocyte model, expressed CHT1 mRNA, but that the CEM and Jurkat T-cell lines did not. Consistent with that finding, specific binding of [3H]hemicholinium-3 (HC-3), an inhibitor of CHT1, and HC-3-sensitive [3H]choline uptake were also detected in MOLT-3 cells. These results suggest that CHT1 plays a role in mediating choline uptake in T-lymphocytes and provides further evidence for the presence of an independent lymphocytic cholinergic system.

Funaki, N., J. Tanaka, et al. (1995). "Highly-sensitive identification of [alpha]-fetoprotein mRNA in circulating peripheral blood of hepatocellular carcinoma patients." *Life Sciences* **57**(17): 1621.

<http://www.sciencedirect.com/science/article/B6T99-3YYTH72-41/2/8c8e01ec8bc3030febce7238e62e5249>

In order to capture hepatocellular carcinoma (HCC) cells in circulating peripheral blood, we made analysis to see if a -fetoprotein (AFP) mRNA exists in the peripheral blood obtained from patients with HCC and also, as a control, from hepatitis-viral-marker-positive patients without HCC and a healthy volunteer. As the number of HCC cells in peripheral blood and the quantity of AFP mRNA are expected to be very small, the analysis was performed by the reverse transcription followed by an original three-step polymerase chain reaction. By this highly sensitive method, 5 of 7 HCC patients were positive for AFP mRNA. These 5 positive patients consisted of three with clinically apparent recurrence, one preoperative patient with tumor thrombus in the portal vein and one recurrence-free patient who developed clinically detectable recurrence three months after this analysis. Neither 4 patients with positive viral markers nor a healthy volunteer was positive. The results suggest that detection of AFP mRNA from HCC patients' peripheral blood by our highly-sensitive RT-PCR may be a practical and powerful tool to diagnose the preoperative spreading of HCC and to monitor its recurrence.

Funaki, N. O., J. Tanaka, et al. (1998). "Quantitative analysis of alpha-fetoprotein mRNA in circulating peripheral blood of patients with hepatocellular and alpha-fetoprotein-producing gastric carcinomas." Life Sciences **62**(21): 1973.

<http://www.sciencedirect.com/science/article/B6T99-3T0TY5N-9/2/b812097676b1bdb7537297815312ae12>

In conjunction with strategies introduced in recent years to identify cancer micrometastasis through amplification of cancer-associated mRNA, we developed a highly sensitive system to detect [alpha] -fetoprotein mRNA in circulating peripheral blood of hepatocellular carcinoma patients. The aim of the present study was to make our original system quantitative. Peripheral venous blood from patients with hepatocellular carcinoma and [alpha] -fetoprotein-producing gastric carcinoma was subjected to reverse transcription followed by our original three-step polymerase chain reaction co-amplifying both the original sequence and our synthetic competitor. We succeeded in modifying our system for quantitative analysis, and investigated the perioperative change, the postoperative change and the change after chemotherapy in order to illustrate the possible application of this method. The quantitative analysis of [alpha]-fetoprotein mRNA present in the peripheral blood represents a useful tool for analyzing the relationship of surgery to recurrence, the effect of chemotherapy, and to predict impending recurrence in patients with hepatocellular and [alpha]-fetoprotein-producing gastric carcinomas.

Funaki, N. O., J. Tanaka, et al. (1997). "Detection of colorectal carcinoma cells in circulating peripheral blood by reverse transcription-polymerase chain reaction targeting cytokeratin-20 mRNA." Life Sciences **60**(9): 643.

<http://www.sciencedirect.com/science/article/B6T99-3RHNJK5-N/2/02703f4bc1c5fff59b100070ea40087f>

For the detection of circulating colorectal carcinoma cells, we investigated the presence of cytokeratin 20 (CK 20) mRNA in the peripheral blood of colorectal carcinoma patients. Application of our published technique resulted in analysis by reverse transcription followed by three-step nested polymerase chain reaction. This analysis could detect a single Colo 205 colon cancer cell mixed with 1 ml of blood. Our system also successfully detected the presence of CK 20 mRNA in actual patients' peripheral blood samples. Our highly sensitive and specific system for the detection of CK-20 mRNA from patients' peripheral blood thus seems to be useful for screening for circulating colorectal carcinoma cells.

Hattori, M.-a., T. Fujioka, et al. (2002). "Preferential expression of ADP-ribosylation factor gene in the chick embryonic gonads." Life Sciences **70**(17): 2031.

<http://www.sciencedirect.com/science/article/B6T99-459BCHR-1/2/5c86818754f4e6794f8644e39de94a3d>

cDNA cloning from chick embryonic gonads subtracted from tissues of the brain, heart, liver, gizzard, mesonephros and skeletal muscle was performed to identify genes with expression unique to embryonic gonads. Several cDNA clones encoding characterized as well as many uncharacterized genes were obtained. ADP-ribosylation factor (ARF) of these identified genes was preferentially expressed in the chick embryonic ovary and testis as revealed by reverse transcription-polymerase chain reaction analysis. Expression of the ARF was evaluated through embryonic development, but no difference in the transcript (relative to glyceraldehyde-3-phosphate dehydrogenase transcript) was observed between the left and right ovaries, and

between the ovary and testis. In addition, the ARF transcript was detected in the gonads on embryonic days 5 to 21. These findings indicate that the ARF is constantly, but preferentially expressed in the embryonic gonads during development.

Hou, M., M. Malmsjo, et al. (1999). "Increase in cardiac P2X1- and P2Y2-receptor mRNA levels in congestive heart failure." Life Sciences **65**(11): 1195.

<http://www.sciencedirect.com/science/article/B6T99-3X9YSFN-C/2/3370cafd4258c51d9079609e7f1413b8>

We wanted to study the expression of P2-receptors at the mRNA-level in the heart and if it is affected by congestive heart failure (CHF). To quantify the P2 receptor mRNA-expression we used a competitive RT-PCR protocol which is based on an internal RNA standard. The P2 receptor mRNA-expression was quantified in hearts from CHF rats and compared to sham-operated rats. Furthermore, the presence of receptor mRNA was studied in the myocardium from patients with heart failure. In the sham operated rats the G-protein coupled P2Y-receptors were expressed at a higher level than the ligand gated ion-channel receptor (P2X1). Among the P2Y-receptors the P2Y6-receptor was most abundantly expressed (P2Y6 > P2Y1 > P2Y2 = P2Y4 > P2X1). A prominent change was seen for the P2X1- and P2Y2-receptor mRNA levels which were increased 2.7-fold and 4.7-fold respectively in the myocardium from the left ventricle of CHF-rats. In contrast, the P2Y1-, P2Y4- and P2Y6-receptor mRNA levels were not significantly altered in CHF rats. In human myocard the P2X1-, P2Y1-, P2Y2-, P2Y6- and P2Y11-receptors were detected by RT-PCR in both right and left atria and ventricles, while the P2Y4-receptor band was weak or absent. In conclusion, most of the studied P2-receptors were expressed in both rat and human hearts. Furthermore, the P2X1- and P2Y2-receptor mRNA were upregulated in CHF, suggesting a pathophysiological role for these receptors in the development of heart failure.

Inoue, K., S. Koizumi, et al. (2003). "Signaling of ATP receptors in glia-neuron interaction and pain." Life Sciences **74**(2-3): 189.

<http://www.sciencedirect.com/science/article/B6T99-49W2118-2/2/24d745003441ab7ebfb44ddabb096dbb>

ATP causes the activation of p38 or ERK1/2, mitogen activated protein kinases (MAPKs) resulting in the release of tumor necrosis factor-[alpha] (TNF) and Interleukin-6 (IL-6) from microglia. We examined the effect of TNF and IL-6 on the protection from PC12 cell death by serum deprivation. When PC12 cells were incubated with serum-free medium for 32 hr, their viability decreased to 30 %. IL-6 alone slightly protected the death of PC12 cells, whereas TNF alone did not show any protective effect. In the meanwhile, when PC12 cells were pretreated with TNF for 6 hr and then incubated with IL-6 under the condition of serum-free, the viability of PC12 cells dramatically increased. TNF induced an increase of IL-6 receptor (IL-6R) expression in PC12 cells at 4-6 hr. These data suggested that 6 hr pretreatment with TNF increased IL-6R expression in PC12 cells, leading to an enhancement of IL-6-induced neuroprotective action. To elucidate the role of p38 in pathological pain, we investigated whether p38 is activated in the spinal cord of the neuropathic pain model. In the rats displaying a marked allodynia, the level of phospho-p38 was increased in the microglia of injury side in the dorsal horn. Intraspinal administration of p38 inhibitor suppressed the allodynia. These results demonstrate that neuropathic pain hypersensitivity depends upon the activation of p38 signaling pathway in microglia in the dorsal horn following peripheral nerve injury.

Kageyama, H., T. Osaka, et al. (2003). "Fasting increases gene expressions of uncoupling proteins and peroxisome proliferator-activated receptor-[gamma] in brown adipose tissue of ventromedial hypothalamus-lesioned rats." Life Sciences **72**(26): 3035.

<http://www.sciencedirect.com/science/article/B6T99-487F0PJ-2/2/4938700a27ee12f04f24566883c266c9>

Uncoupling proteins (UCPs) are supposed to be involved in diet-induced thermogenesis. Their activities are usually elevated by feeding and reduced by fasting in normal animals. To investigate whether fasting affects the expression of UCPs mRNA in brown adipose tissue (BAT) of bilateral ventromedial hypothalamus (VMH)-lesioned rats, we determined the gene expression of UCP1, UCP2 or UCP3 in BAT of VMH-lesioned rats and examined oxygen consumption in these rats under fed or 48-h fasted conditions. Northern blotting revealed no difference in the expression of UCPs mRNA in BAT between VMH-lesioned and sham-operated rats under the fed condition, however, expressions were increased markedly in BAT of VMH-lesioned rats under the fasted condition. Under the fed condition, no difference in oxygen consumption was observed between VMH-lesioned and sham-operated rats. Under the fasted condition, oxygen consumption decreased in both rats, however, it decreased in VMH-lesioned less than in sham operated rats. To explore the mechanism that fasting elevated BAT UCPs mRNA in VMH-lesioned rats, we measured peroxisome proliferator-activated receptor (PPAR)-[gamma] mRNA and protein in BAT, because PPAR-[gamma] agonist can elevate UCPs mRNA levels in BAT. Under the fed condition, no differences in the expression of PPAR-[gamma] mRNA and protein content were observed between in BAT of VMH-lesioned and sham-operated rats. Under the fasted condition, however, both increased in BAT of VMH-lesioned rats. These results suggest that VMH-lesions enhance the gene expression of UCPs in BAT under long-term fasting as a defensive reaction to inhibit the reduction of body temperature through an increase in PPAR-[gamma] activity.

Katavic, V., D. Grcevic, et al. (2003). "Non-functional Fas ligand increases the formation of cartilage early in the endochondral bone induction by rhBMP-2." Life Sciences **74**(1): 13.

<http://www.sciencedirect.com/science/article/B6T99-49STN7H-3/2/6e893ea6358ff4848b9dad50ce6aacb0>

It has previously been shown that mice with a defect in Fas ligand-mediated apoptosis have an enhancement of ectopic bone formation. We investigated the expression of bone-related markers - alkaline phosphatase, collagen, bone sialoprotein, osteocalcin, osteopontin, and bone morphogenetic proteins (BMP) -2, -4, and -7; and cytokines interleukin-1[alpha] (IL-1), IL-1[beta], and tumor necrosis factor-[alpha] (TNF-[alpha]) in ectopic new bone induced by recombinant human (rh) BMP-2 in mice without functional Fas-ligand (gld mice). At day 6 after rhBMP-2 implantation, gld mice formed more cartilage and mesenchyme compared with their wild type littermates. At later stages, gld mice did not differ from the control mice in the volume of newly formed tissue, expressing higher level of BMP genes and lower levels of genes involved in osteoblast maturation - bone sialoprotein and osteopontin. Differences in the levels of expression of IL-1[alpha] and TNF-[alpha] were observed only at day 12 after rhBMP-2 implantation. These results suggest that gld mice have an increased recruitment of cells of mesenchymal origin and an abnormal pattern of differentiation and maturation of the newly formed mesenchymal tissues.

Kishimoto, Y., K. Wada, et al. (1997). "Quantitative analysis of cyclooxygenase-2 gene expression on acute gastric injury induced by ischemia-reperfusion in rats." Life Sciences **60**(8): PL127.

<http://www.sciencedirect.com/science/article/B6T99-3RHNJK5->

15/2/8852d99180513dfe8666b1461fa88f5b

The rat model of acute gastric damage induced by ischemia-reperfusion (I-R) has been used to evaluate the protective effect of various drugs on gastric injury. However, the quantitative expression state of cyclooxygenase-2 (COX-2), a protein which induces cytoprotective prostaglandins during inflammation, is still unknown in acute gastric injury induced by I-R. Therefore, we have quantitatively investigated the level of expression of COX-2 mRNA in injured gastric tissue of this model using the reverse transcription-competitive polymerase chain reaction method. The mRNA for COX-2 was expressed at low or undetectable levels in the normal gastric tissues in control rats, which were fasted for 18 hrs without I-R. The mRNA levels of COX-2 in injured gastric tissues were higher than those of control tissues between 6 hrs and 48 hrs after I-R. The maximum expression of COX-2 mRNA was recorded at 24 hrs (approximately a 200-fold increase). The expression state of COX-2, which has been ascertained in this study, should be useful in evaluating the effect of various drugs on the expression of COX-2 in acute gastric damage.

Liu, Z.-J., M. Maekawa, et al. (2003). "The multiple promoter methylation profile of PR gene and ER[alpha] gene in tumor cell lines." *Life Sciences* **73**(15): 1963.

<http://www.sciencedirect.com/science/article/B6T99-490H4NG-1/2/792c1e218beb6e76ecf29256ce844f35>

The changes of methylation status of various gene promoters are a common feature of malignant cells and these changes can occur early in the progression process. Therefore, abnormal methylation can be used as cancer marker. Such studies will first require the development of a panel of methylated markers that are methylated in cancer tissues but unmethylated in normal tissues or methylation status is different between cancer tissues and normal tissues. By using methylation-specific PCR (MSP) assay method, we observed alterations in DNA methylation at the double promoter regions of the progesterone receptor (PR) gene and estrogen receptor (ER[alpha]) gene in various tumor cell lines. Compared with normal white blood cell, the methylation status of PRA promoter in various cancer cell lines changed from unmethylation pattern to methylation pattern. That of PRB promoter changed from both unmethylated and methylated alleles to only methylated allele. The methylation status of ER[alpha]-A and ER[alpha]-B promoter in various cancer cell lines are cell -specific. This study indicates that PR promoter methylation may be a molecular marker in various cancer detections. And the methylation status of ER[alpha]-A and ER[alpha]-B is cell-specific.

Mao, T. K., J. Powell, et al. (2000). "The effect of cocoa procyanidins on the transcription and secretion of interleukin 1[beta] in peripheral blood mononuclear cells." *Life Sciences* **66**(15): 1377.

<http://www.sciencedirect.com/science/article/B6T99-3YXB9SD-1/2/71a41c13f5ebaf4156571a6df0ac2a89>

Recent data has demonstrated that cacao liquor polyphenols (procyanidins) have antioxidant activity, inhibit mRNA expression of interleukin-2 and are potent inhibitors of acute inflammation. Given the widespread ingestion of cocoa in many cultures, we investigated whether cocoa, in its isolated procyanidin fractions (monomer through decamer), would modulate synthesis of the pro-inflammatory cytokine, interleukin-1[beta]. Both resting and phytohemagglutinin (PHA)-stimulated peripheral blood mononuclear cells (PBMC) were investigated at the levels of transcription and protein secretion. Individual cocoa fractions were shown to augment constitutive IL-1[beta] gene expression, although values varied between subjects. Interestingly, the smaller fractions of cocoa

(monomer-tetramer) consistently reduced IL-1[β] expression of PHA-stimulated cells by 1-15%, while the larger oligomers (pentamer-decamer) increased expression by 4-52%. These data, observed at the transcription level, were reflected in protein levels in PHA-induced PBMC. The presence or absence of PHA did not alter the effects of the cocoa procyanidins with the exception of the pentamer. This study offers additional data for the consideration of the health-benefits of dietary polyphenols from a wide variety of foods, including those benefits associated specifically with cocoa and chocolate consumption.

Mengheri, E., L. Ciapponi, et al. (1996). "Cytokine gene expression in intestine of rat during the postnatal developmental period: Increased IL-1 expression at weaning." *Life Sciences* **59**(15): 1227.

<http://www.sciencedirect.com/science/article/B6T99-3W2T831-6/2/2f8bf146ca53c502e0d6302462c6e5ac>

In the present study we have investigate whether cytokines are constitutively and differently expressed in intestine during the differentiative processes that take place at weaning. We have analyzed the expression of IL-1[β], IL-2, IL-4 and IFN[γ] by polymerase chain reaction in Peyer's patches (PP) and in intestine deprived of PP (I-PP) of rats from 16 to 30 days of age. The results showed a constitutive and marked expression of the cytokines already before weaning, with the exception of IL-2 in PP and IFN[γ] in I-PP. IL-[β] was the only cytokine to show a different expression at various ages with an initial increase at 19 days and a further elevation at 21 days when intestinal epithelium passes through major differentiative stages, suggesting an involvement of this cytokine in intestinal development. We have also tested whether treatment of rats with the immunosuppressor cyclosporin A (CsA) could affect intestinal differentiation. The results showed that only some markers of differentiation were affected (proliferation of staminal crypt cells and length of crypts). This was probably due to a direct effect rather than an immunomediated effect of CsA, since treatment of three intestinal cell lines (Caco-2, HT-29, FRIC) with CsA indicated that this drug can exert a cytostatic activity on intestinal cells.

Miyamoto, A., Y. Yamazaki, et al. (2003). "Enhancement of endotoxin-induced vascular hyporeactivity to phenylephrine in the thoracic aortas of Mg-deficient rats ex vivo." *Life Sciences* **73**(21): 2713.

<http://www.sciencedirect.com/science/article/B6T99-49H6BGJ-3/2/731d1f2fc76fbed391d32945c0e9ae05>

Since endotoxin lethality is enhanced by Mg deficiency in animals, we determined whether endotoxin-induced vascular hyporeactivity to phenylephrine (PE) is enhanced in Mg-deficient rats. Normal and Mg-deficient adult male Wistar rats were injected with *Escherichia coli* 011: B4 lipopolysaccharide (1 or 5 mg/kg, i.p.). Six h later, rings prepared from their thoracic aortas showed severe hyporeactivity to PE. This was more pronounced in the Mg-deficient rats, and was reversed by in vitro treatment with a highly selective inducible nitric oxide (NO) synthase inhibitor, 1400 W, or a highly selective soluble guanylyl cyclase inhibitor, ODQ. However, reversal required high doses of both inhibitors in Mg-deficient rats. Endotoxemia for 6 h was associated with elevated serum interleukin (IL)-1[β] and tumor necrosis factor (TNF)-[α] levels, and strong TNF receptor mRNA expression in the abdominal aortas, which were significantly greater in the Mg-deficient rats. Treatment of the thoracic aortas, isolated from control and Mg-deficient rats before endotoxic challenge, with IL-1[β] or TNF-[α] for 6 h in vitro caused hyporeactivity to PE, but its severity did not differ significantly between the two groups. These results suggest that high serum IL-1[β] and TNF-[α] levels, and increased TNF receptor production in the vascular tissue, contribute to vascular hyporeactivity to PE in endotoxemia, and to its enhancement in Mg-deficient rats, via NO/cGMP signaling.

Nara, M., T. Kanda, et al. (1999). "Running exercise increases tumor necrosis factor-[alpha] secreting from mesenteric fat in insulin-resistant rats." Life Sciences **65**(3): 237.

<http://www.sciencedirect.com/science/article/B6T99-3X05HTX-11/2/e914656134de1d8140d842a2cce532c8>

Tumor necrosis factor-[alpha] (TNF-[alpha]) is an important mediator of insulin resistance in obese subjects, through its overexpression in fat tissue. However, how exercise can modify the expression of TNF-[alpha] is controversial. We examined TNF-[alpha] in adipose tissue using an animal model of insulin resistance that was produced by feeding rats a diet high in sucrose. The rats were allocated to one of three groups: those receiving a starch-based diet (control group): those fed a high-sucrose diet (sucrose-fed group): and those fed a high-sucrose diet and given wheel exercise (exercised group). The animals were allowed to eat and drink ad lib for 4 or 12 weeks (4 wk: control N = 7, sucrose-fed N = 7, exercised N = 10; 12 wk: control N = 5, sucrose-fed N = 5, exercised N = 9). The voluntary wheel exercise was initiated with the feeding of the high-sucrose diet. The rats in the exercise groups ran 15 +/- 3 km/week. We showed that 12-week voluntary running exercise significantly (P Eq/L vs 141 +/- 11 Eq/L) and free fatty acid (0.98 +/- 0.07 Eq/L vs 1.4 +/- 0.05 mEq/L) concentrating in portal vein blood were reduced compared to sucrose-fed group. The amounts of fatty tissue both in mesenteric and subcutaneous tissues were significantly (P < 0.05) decreased through running exercise. We consider that up-regulation of TNF-[alpha] in mesenteric fat may be a compensatory mechanism for the reduction of fatty acid in adipose tissues and this change could control metabolic homeostasis during exercise to modulate a hyperinsulinemic state.

Ohashi, S.-i., H. Kaji, et al. (1995). "Effect of fasting and growth hormone (GH) administration on gh receptor (GHR) messenger ribonucleic acid (mRNA) and GH-binding protein (GHBP) mRNA levels in male rats." Life Sciences **57**(18): 1655.

<http://www.sciencedirect.com/science/article/B6T99-3YYTH6C-3F/2/edc23366ae0c793fbaa6989260c5f20c>

To elucidate whether GHR and GHBP are coordinately regulated or not, we studied the effect of fasting with or without GH administration on the GHR and GHBP mRNAs in the liver as well as in extrahepatic tissues in rats. Tissues were collected from 7-week-old male rats by decapitation 1, 3, and 7 days after the start of fasting. Liver GHR mRNA levels were not affected 1 day after the start of fasting but progressively decreased for the subsequent 3 and 7 days of fasting as compared with those in control rats fed ad libitum. In contrast, liver GHBP mRNA levels significantly rose after 1 day fasting, returned to the control level after 3 days and further reduced after 7 days of fasting. Changes in GHBP mRNA level after fasting were different among the tissues. A transient increase in GHBP mRNA levels was observed in muscle and heart as well as liver, while the GHBP mRNA levels in fat tissues did not change throughout 7 days of fasting. Next, bovine GH(bGH) was administered ip to the fasted rats and control fed rats for either 1 day(100mg, tid) or 5 days(150mg, daily). In fed rats, liver GHR mRNA level was significantly increased by 1 day bGH treatment, but after 5 days treatment with bGH it was not different from the level in saline-injected control. Accordingly, net increment of plasma IGF-I was 296.0 ng/ml with 1 day bGH treatment and 234.2 rig/ml with bGH administration for 5 days. In fasted rats, liver GHR mRNA level did not changed after 1 day treatment with bGH, but markedly decreased 5 days after bGH administration. Net increment of plasma IGF-I was slightly reduced to 284 ng/ml with 1 day treatment with bGH, and markedly decreased to 37.0 with bGH administration for 5 days. The effect of GH administration on liver GHBP mRNA level was virtually absent in either fasting or fed state. These findings suggest that GHR and GHBP mRNAs in the liver are expressed in different ways and that expression of GHBP mRNA is differently regulated among

tissues.

Pietruck, C., G.-X. Xie, et al. (1999). "Alternative exon splicing of cyclic AMP response element-binding protein in peripheral sensory and sympathetic ganglia of the rat." Life Sciences **65**(21): 2205.

<http://www.sciencedirect.com/science/article/B6T99-3XX6KNH-5/2/e72d01f6881ea6e50ce27b975671c1d8>

Alternative splicing patterns of cyclic AMP response element-binding protein (CREB) in dorsal root ganglia, lumbar sympathetic ganglia and several peripheral tissues of the rat have been investigated by an exon-flanking polymerase chain reaction strategy. A series of RT-PCR with primer pairs flanking all possible alternative splicing sites (corresponding to a genomic region with at least one full exon and two flanking introns) has revealed multiple tissue specific splice variants. These include some novel transcripts that lack the phosphorylation site and part of the leucine zipper region which is crucial for dimerization and DNA binding. Some isoforms previously reported as testis-specific were also detected in rat peripheral ganglia and other tissues. Notably, splicing patterns are specific for some regions. Some of the splice variants indicate inhibitory functions due to lacking phosphorylation sites or partially missing DNA-binding or leucine zipper domains. These findings suggest a complex expression and functional regulation of CREB in peripheral tissues including dorsal root and sympathetic ganglia.

Sango, K., H. Horie, et al. (2002). "Diabetes is not a potent inducer of neuronal cell death in mouse sensory ganglia, but it enhances neurite regeneration in vitro." Life Sciences **71**(20): 2351.

<http://www.sciencedirect.com/science/article/B6T99-46R0BWM-4/2/f467496d5906f8373aff8b0e50f81e08>

We examined the effects of diabetes on the morphological features and regenerative capabilities of adult mouse nodose ganglia (NG) and dorsal root ganglia (DRG). By light and electron microscopy, no apoptotic cell death was detected in the ganglia obtained from either streptozotocin (STZ)-induced diabetic or normal C57BL/6J mice in vivo. Neurite regeneration from transected nerve terminals of NG and DRG explants in culture at normal (10 mM) and high (30 mM) glucose concentrations was significantly enhanced in the diabetic mice. Chromatolytic changes (i.e. swelling and migration of the nucleus to an eccentric position in the neurons, and a loss of Nissl substance in the neuronal perikarya) and apoptotic cell death (less than one-fifth of the neurons) in the cultured ganglia were present, but neither hyperglycemia in vivo nor high glucose conditions in vitro altered the morphological features of the ganglia or the ratios of apoptotic cells at 3 days in culture. By semiquantitative RT-PCR analysis, the mRNA expressions of ciliary neurotrophic factor (CNTF) in DRG from both mice were down-regulated at 1 day in culture. The expression in diabetic DRG, but not in control DRG, was significantly up-regulated at later stages (3 and 7 days) in culture. In summary, hyperglycemia is unlikely to induce cell death in the sensory ganglia, but enhances the regenerative capability of vagal and spinal sensory nerves in vitro. The up-regulation of CNTF mRNA expression during the culture of diabetic DRG may play a role in the enhanced neurite regeneration.

Takahata, T., N. Yasui-Furukori, et al. (2003). "Nucleotide changes in the translated region of SCN5A from Japanese patients with Brugada syndrome and control subjects." Life Sciences **72**(21): 2391.

<http://www.sciencedirect.com/science/article/B6T99-481N39K-4/2/4e19138efc777137fcbd5aa218911e2c>

The mutations of the SCN5A gene have been implicated to play a pathogenetic role in Brugada syndrome, which causes ventricular fibrillation. To determine the Brugada-associated mutations in Japanese patients, facilitate pre-symptomatic diagnosis, and allow genotype-phenotype studies, we screened unrelated patients with Brugada syndrome for mutations. DNAs from 6 Japanese patients were obtained and the sequence in the translated region of SCN5A was determined. We could not find the mutations reported previously, but found 17 sites of nucleotide change, consisting of 7 synonymous and 10 non-synonymous nucleotide changes in our patients. Among them, two non-synonymous nucleotide changes (G1663A and G5227A) are specific to our patients and these changes were not found in 53 healthy controls. In 4 patients out of 6, no specific nucleotide change for Brugada syndrome could be detected. Our findings demonstrating no patient-specific change in the translated region of the SCN5A gene among two thirds of the small number of patients examined here imply that another gene other than the SCN5A may be associated with this disease, supporting previous investigations in Japan and other countries.

Takase, S., K. Suruga, et al. (1995). "Relationship between perinatal appearance of cellular retinol-binding protein, type II and retinal reductase activity in chick liver." *Life Sciences* **58**(2): 135.

<http://www.sciencedirect.com/science/article/B6T99-3VX9XS9-J/2/9ab373902d2a0d9bb11ee3e3eb6587ee>

To explore a role of the transiently appearing cellular retinol-binding protein, type II (CRBP(II)) in perinatal chick liver, we have examined whether the relationships exist among the perinatal changes in hepatic CRBP(II) protein and mRNA levels, retinal reductase activity and [beta]-carotene levels in liver and serum. Northern blot analysis for hepatic CRBP(II) revealed a transient expression of CRBP(II) mRNA around hatching. The protein of CRBP(II) was also expressed transiently and the highest levels of CRBP(II) were found in the livers 1-3 days after birth. The retinal reductase activity was very low at embryonic age, but its activity rapidly rose at hatching, peaking at 1 day after birth, followed by a gradual decrease to a lower level in 7-day-old chicks. This perinatal pattern of the retinal reductase activities was similar to the pattern of transient appearance of the hepatic CRBP(II), and was also paralleled to the developmental changes in serum and liver [beta]-carotene concentrations. These findings suggest that hepatic CRBP(II) transiently appearing during the perinatal period may involve in metabolizing hepatic [beta]-carotene, directing the retinal to the retinal reductase and leading further to the subsequent esterification of the converted retinol.

Tsukiji, J., K. Sango, et al. (2004). "Long-term induction of [beta]-CGRP mRNA in rat lungs by allergic inflammation." *Life Sciences* **76**(2): 163.

<http://www.sciencedirect.com/science/article/B6T99-4DN8G64-2/2/01b21ab2616ec51174cf28114fcd3aef>

Calcitonin gene-related peptide (CGRP) is one of the major neuropeptides released from sensory nerve endings and neuroendocrine cells of the lung. Two CGRP isoforms, [alpha]- and [beta]-CGRP, have been identified in rats and humans, but no studies have attempted to reveal direct evidence of differences in action or location of these isoforms in allergic inflammation (AI). We investigated mRNA expressions of [alpha]- and [beta]-CGRP in lungs, nodose ganglia (NG), and dorsal root ganglia (DRG) of an animal model for AI of the airways, utilizing a model created by sensitizing Brown Norway (BN) rats with ovalbumin (OVA). By semiquantitative RT-PCR analysis,

long-lasting enhanced expression of the [beta]-CGRP mRNA was shown in the lungs of the AI rats (14.5-fold enhancement at 6 hr, 8.1-fold at 24 hr, and 3.7-fold at 120 hr after OVA-challenge compared to the level in the lungs of phosphate-buffered saline (PBS)-challenged control rats). In contrast, the mRNA expression of the [alpha]-CGRP in AI lungs showed only a transient increase after OVA-challenge (2.7-fold at 6 hr) followed by a lower level of expression (0.5-fold at 48 hr and 0.6-fold at 120 hr). The mRNA expressions of both isoforms in NG, but not in DRG, were transiently up-regulated at 6 hr after antigen challenge. In situ RT-PCR in combination with immunohistochemical analysis revealed that [beta]-CGRP was expressed in neuroendocrine cells in clusters (termed neuroepithelial bodies [NEBs]) in AI lungs. These results indicate that the long-term induction of [beta]-CGRP in NEBs may play an important role in pulmonary AI such as bronchial asthma.

Vrana, K. E., P. J. Rucker, et al. (1994). "Recombinant rabbit tryptophan hydroxylase is a substrate for cAMP-dependent protein kinase." *Life Sciences* **55**(13): 1045.

<http://www.sciencedirect.com/science/article/B6T99-47548Y8-J9/2/dc9a0f329fed636149e1588fa867f2a6>

A full-length cDNA clone for rabbit tryptophan hydroxylase (TPH) was modified and subcloned into a bacterial expression vector. Expression of this gene in the protease-deficient strain of bacteria, BL21[DE3], produced TPH immunoreactive protein which exhibited enzyme activity. Treatment of the recombinant enzyme (in bacterial extracts) with the purified catalytic subunit of the cAMP-dependent protein kinase and [γ -³²P]-ATP resulted in specific phosphorylation of TPH. This expression system provides a means of generating and purifying large amounts of this important enzyme. Moreover, these experiments establish that TPH will serve as an in vitro substrate for cAMP-dependent protein kinase.

Xie, G.-X., T. Meuser, et al. (1999). "Presence of opioid receptor-like (ORL1) receptor mRNA splice variants in peripheral sensory and sympathetic neuronal ganglia." *Life Sciences* **64**(22): 2029.

<http://www.sciencedirect.com/science/article/B6T99-3WWTD97-7/2/acfaf4d19afdbd2d008092822c9c1353>

The expression of ORL1 receptor mRNA splice variants is determined in peripheral sensory and sympathetic ganglia and compared to mRNA expression for the three classic opioid receptor subtypes (mu, delta, and kappa) using the method of reverse transcription-polymerase chain reaction. ORL1, mu, delta and kappa receptor subtype mRNAs are present in human dorsal root ganglia (DRG) and trigeminal ganglia and rat DRG. ORL1, mu and delta receptor subtype mRNAs are present in rat superior cervical ganglia and only ORL1 and delta receptor mRNAs are present in rat lumbar sympathetic ganglia. Both the ORL1 mRNA splice variants are present in sensory and sympathetic ganglia, however, expression of the shorter ORL1 receptor mRNA dominates over expression of the longer splice variant in rat brain and DRG, whereas, expression of the longer splice variant is dominant in sympathetic ganglia.

Xu, Z., B. Dai, et al. (1994). "Gastrin gene expression in human colon cancer cells measured by a simple competitive PCR method." *Life Sciences* **54**(10): 671.

<http://www.sciencedirect.com/science/article/B6T99-474YKY4-1DP/2/2be6dbe850711eed068bb3dbae6a7f12>

Gastrin is mitogenic for several colon cancers and is postulated as an autocrine growth factor for colon cancer cells. In the present study we report the development of a simple competitive polymerase chain reaction (PCR) method for measuring relative abundance of gastrin gene expression in colon cancer cells. Primers flanking exons 2 and 3 of the gastrin gene were utilized for co-amplification of cDNA and genomic DNA. The amplification of genomic DNA was distinguished from that of cDNA by the presence of the 130 bp intron sequence which was resolved by electrophoresis on agarose gels. A standard reaction of competitive PCR, using known concentrations of genomic DNA and cDNA, was first established. The steady state levels of gastrin mRNA were next quantitated in three human colon cancer cell lines (HCT-116, Colo-205 and DLD-1) by competitive PCR. Gastrin mRNA levels in these cell lines ranged from ~0.1 to 1.0 fmoles/mg total RNA (~2-25 copies of gastrin mRNA per cell). This low to moderate levels of gastrin were expressed by human colon cancer cell lines which may function as autocrine growth factors for colon cancers.

Yamamoto, J., K. Ihara, et al. (2004). "Characteristic expression of aryl hydrocarbon receptor repressor gene in human tissues: Organ-specific distribution and variable induction patterns in mononuclear cells." *Life Sciences* **74**(8): 1039.

<http://www.sciencedirect.com/science/article/B6T99-4B0T00G-3/2/532bf5586dc34fd737653c127c049dac>

To investigate the expression of aryl hydrocarbon receptor repressor (AhRR) and related molecules in various tissues and the effects of aromatic hydrocarbons (AHs) on their expression, we developed a reliable technique of quantification of human AhRR as well as aryl hydrocarbon receptor (AhR), AhR nuclear translocator (ARNT) and cytochrome P450 1A1 (CYP1A1) mRNA by real-time TaqMan PCR method. First, we examined the expression of these genes in human adult or fetal tissues. The levels of AhRR expression were extremely high in testis, very high in lung, ovary, spleen and pancreas from adults, whereas those were low in those from fetuses. On the other hand, CYP1A1 expression was extremely high in lung, and AhR and ARNT were ubiquitously expressed in almost all tissues. Second, we compared the expression levels of these genes in mononuclear cells (MNCs) from various sources. Comparison of the basal expression levels of these genes in MNCs demonstrated that MNCs from umbilical cord blood showed higher AhRR or CYP1A1 expression than those from adults. The induction of AhRR or CYP1A1 expression by 3-methylcholanthrene (3-MC) was observed in MNCs from adults but not from umbilical cord blood. Consequently, there existed characteristic differences in the basal levels of AhRR and CYP1A1 expression in MNCs, as well as in their inducibility by 3-MC among MNCs from various types of human bloods. These results will provide basic information for a possible application of AhRR and CYP1A1 measurements to evaluate AH exposure in vivo.

Ying, S.-Y., S.-Q. Li, et al. (1995). "Expression and localization of inhibin [alpha]-subunit in rat retinal photoreceptor cells." *Life Sciences* **57**(1): 45.

<http://www.sciencedirect.com/science/article/B6T99-3YYTHNJ-BP/2/53a8f632190c92b468921a2ecb1717b1>

To determine whether rat retinal photoreceptor cells produce inhibin, a molecule closely related to activin, a multifunctional growth factor in the transforming growth factor [beta] superfamily (TGF[beta]), we have conducted immunohistochemistry using specific antibodies for inhibin which were raised against a synthetic N-terminal fragment of the [alpha]-subunit of inhibin. The mature inhibin molecule was identified at both the inner and outer segments of photoreceptor cells. To determine if messenger RNA for the [alpha]-subunit of inhibin is expressed in the retinal cells, both in situ hybridization with a specific probe and the reverse transcription-polymerase chain

reaction (RT-PCR) technique with primers specific for the [alpha]-subunit of inhibin were used. Messenger RNA expression of the [alpha]-subunit of inhibin was detected by RT-PCR and localized in the photoreceptor cells as determined by in situ hybridization. In addition, the identity of the cDNA product of RT-PCR was verified with Southern analysis and DNA sequencing. The localization of mature inhibin protein and its corresponding message to photoreceptor cells suggest that inhibin may have a paracrine function in the retina, perhaps in the photoreceptor cells themselves.

Lung Cancer (15)

Breuer, R. H. J., P. J. F. Snijders, et al. "Expression of the p16INK4a gene product, methylation of the p16INK4a promoter region and expression of the polycomb-group gene BMI-1 in squamous cell lung carcinoma and premalignant endobronchial lesions." *Lung Cancer In Press, Corrected Proof* <http://www.sciencedirect.com/science/article/B6T9C-4FCG28Y-3/2/de413e8a15c8585ba1ca3ef9e593ab31>

SummaryIt is generally assumed that squamous cell carcinoma develops in a stepwise manner from normal bronchial epithelium towards cancer by the accumulation of (epi)genetic alterations. Several mechanisms including mutations and homozygous deletions or hypermethylation of the p16INK4a promoter region can cause loss of p16 expression. Recent studies suggest overexpression of the polycomb-group gene BMI-1 might also down-regulate p16 expression. In this study, we analyzed the p16 expression in relation to the methylation status of the p16 promoter region of the p16INK4a gene and the expression of BMI-1 in bronchial squamous cell carcinomas (SCC) and its premalignant lesions. Nine (69%) SCC showed loss of p16 expression and 10 (77%) showed expression of BMI-1. Of four p16 positive samples two (50%) were BMI-1 positive, whereas among nine p16 negative samples, eight (89%) revealed BMI-1 staining. Four (44%) p16 negative samples were hypermethylated at the p16INK4a promoter region; the other p16 negative tumors that showed no hypermethylation revealed BMI-1 staining. Only two premalignant lesions showed absence of p16 expression, of which one (carcinoma in situ) was hypermethylated at the p16INK4a promoter region and the other (severe dysplasia) showed BMI-1 expression. In total, 11 precursor lesions (48%) revealed BMI-1 expression. In conclusion, the results of this study suggest that loss of p16 expression by promoter hypermethylation is inconsistently and occurs late in the carcinogenic process at the level of severe dysplasia. To what extent overexpression of the polycomb-group protein BMI-1 attributes to down regulating of p16 expression remains unclear.

Gao, W.-M., H. H. Mady, et al. (2003). "Comparison of p53 mutations between adenocarcinoma and squamous cell carcinoma of the lung: unique spectra involving G to A transitions and G to T transversions in both histologic types." *Lung Cancer* **40**(2): 141.

<http://www.sciencedirect.com/science/article/B6T9C-480CRM1-2/2/cf958b9032120f2627c75f528fb15014>

The p53 gene is frequently mutated in lung tumors, and mutations may be caused by both polycyclic aromatic hydrocarbons (PAHs) and nitrosamines found in tobacco smoke. The two major forms of lung cancer, adenocarcinoma (AC) and squamous cell carcinoma (SCC), are known to differ in the proportion of tumors exhibiting p53 mutation, and may also differ in the

mutational spectra produced. Previous studies comparing p53 mutational spectra between AC and SCC of the lung have been limited by small sample size. We examined p53 mutations in exons 5-8 in 202 cases of AC and 82 cases of SCC from smoking lung cancer patients in the Western Pennsylvania region. The percent of cases with p53 mutation was significantly lower in ACs (40/202, 20%) compared to SCCs (29/82, 35%, $P=0.006$). The proportion of mutations present that were G to T transversions was not significantly different between the two tumor types (52% of p53 mutations in AC compared to 32% in SCC). G to A transitions either did not differ in frequency in the two types of lung cancer (20% of mutations in AC and 24% of mutations in SCC). A distinct spectrum was observed, however, in the p53 mutation pattern in the two types of lung cancer. ACs showed a strong preference for a mutational hotspot at codons 248 and 249, while squamous cell tumors showed mutational events spread throughout exons 5-8, with a preference for codon 267. Mutations at codon 267 in SCC were all C to T transitions that occurred at CpG sites. Both tumor types demonstrated preferential mutation of the non-transcribed strand (100% of all G to T transversions and 55% of the G to A transitions). These results suggest that p53 mutations in both types of lung tumors may arise from adduction by both PAHs and nitrosamines. Mutations arising in ACs appear selectively in regions of p53 that produce more rigid proteins, suggesting a drastic change in p53 function is needed to result in ACs, while less constrained changes in p53 function can result in SCCs. Mutation in p53 was not found to be related to patient survival in this group of patients, while tumor size and degree of differentiation were poor survival predictors.

Gessner, C., H. Kuhn, et al. (2004). "Detection of p53 gene mutations in exhaled breath condensate of non-small cell lung cancer patients." *Lung Cancer* **43**(2): 215.

<http://www.sciencedirect.com/science/article/B6T9C-4B4VPNH-2/2/92db0969ccb19672e3d02e5b779c1463>

Early diagnosis of lung carcinoma is greatly desired. A potential source of early information regarding the process of cancerisation in the airways is exhaled breath condensate (EBC). The direct approach to detecting cancerisation is examining DNA from the area of chronic damage, i.e. airways and lung parenchyma. We therefore investigated DNA in EBC of patients with NSCLC and healthy volunteers. Human DNA was amplified by PCR in exhaled breath condensate and used to detect p53 mutations. A PCR of the [beta]-actin gene fragment was used to detect human DNA in each of the EBC samples. In 65.7% of the samples, the [beta]-actin gene was found. Extracted DNA as well as native EBC were equally suited as starting material for amplification. Mutations of the p53 gene were investigated in all EBC samples of NSCLC patients. p53 exons 5-8 were amplified using nested PCR and subsequently sequenced. Mutations were found in four of the patients ($n=11$; 36.4%) while no mutation was found in volunteers ($n=10$). Mutations detected in EBC were also compared with those of corresponding tumor tissue. Different point mutations in EBC and tumor tissue were revealed in all cases. Our findings demonstrate that exhaled breath condensate may be used for analysis of somatic gene mutations in an area of direct tobacco-related DNA damage.

Gotoh, K., Y. Yatabe, et al. (1998). "Frequency of MAGE-3 gene expression in HLA-A2 positive patients with non-small cell lung cancer." *Lung Cancer* **20**(2): 117.

<http://www.sciencedirect.com/science/article/B6T9C-3VCKRM0-6/2/2eaa0a27e5a02d1bf2f81b7179db520e>

Melanoma tumor antigens, MAGE-1 and -3 are presented on HLA-A1 and -Cw*1601, or -A1 and -A2, respectively, to the corresponding cytotoxic T lymphocytes (CTL). If CTL recognizing these antigens were generated in patients, clones of positive tumor cells should be eliminated. To

ascertain whether such an immunological response is active in patients with lung cancer and to determine what fraction of lung cancer patients are candidates for MAGE oriented immunotherapy, we assessed the relationship between HLA-A1 or -A2 expression and MAGE-1 or -3 gene expression in their tumors. MAGE-1 and -3 were detected in 18/55 (33%) and 23/55 (42%), respectively, by reverse transcriptase (RT)-polymerase chain reaction (PCR). Allele specific PCR revealed HLA-A1 and -A2 alleles to be expressed in 0/55 (0%) and 22/55 (40%) of our cohort, respectively. Among the 22 patients with HLA-A2 genotype, expression of HLA class I antigens detectable by immunohistochemistry was lost in five (23%) cases. The frequency of MAGE-3 expression in HLA-A2 patients was 5/17 (29%), somewhat lower than that of patients without HLA-A2 expression, 18/38 (47%), although the difference was not statistically significant ($P=0.17$). Neither was there a significant association between HLA-A2/MAGE-3 co-expression and survival ($P=0.15$, logrank test). We conclude that there is no clear evidence for elimination of lung cancers co-expressing HLA-A2 and MAGE-3 in vivo. Approximately 10% (5/55) of Japanese lung cancer patients are potential candidates for MAGE-3-based immunotherapy.

Junker, N., J. S. Johansen, et al. "Expression of YKL-40 by peritumoral macrophages in human small cell lung cancer." Lung Cancer **In Press, Corrected Proof**

<http://www.sciencedirect.com/science/article/B6T9C-4F6MDHH-2/2/be2ce66bcd2f12a7a0217340b75d56b>

Summary YKL-40 is a 40 kDa protein with possible involvement in tissue remodeling, cell proliferation and angiogenesis. Elevated serum YKL-40 levels in patients with metastatic cancers (including small cell lung cancer (SCLC)) are associated with poor prognosis. The aim of this study was to identify the cellular source of YKL-40 in SCLC patient biopsies and in a panel of 20 human SCLC lines cultured in vitro and in vivo in nude mice. In general, the SCLC cell lines had no or very limited (human) YKL-40 expression, whereas, by RT-PCR a pronounced murine (i.e., stromal) YKL-40 expression was present in all tumors. YKL-40 mRNA transcripts were detected by in situ hybridization in 9 of 10 biopsies from SCLC patients, and in each case the signal was localized in the peritumoral stroma in cells of typical macrophage morphology (confirmed by a CD68 macrophage specific stain). No YKL-40 mRNA expression was found in the cancer cells, in macrophages infiltrating the solid tumor areas, or in non-malignant tissue. In conclusion, the predominant source of elevated serum YKL-40 in SCLC is peritumoral macrophages.

Kawai, H., K. Kiura, et al. (2002). "Characterization of non-small-cell lung cancer cell lines established before and after chemotherapy." Lung Cancer **35**(3): 305.

<http://www.sciencedirect.com/science/article/B6T9C-453598H-6/2/281ca568028ee048134c6feb3c89922>

We established several in vitro drug-resistant cell lines after continuous, long-term exposure of each drug to elucidate mechanisms of drug resistance. Whether drug resistance in these in vitro resistant cell lines reflects clinical drug resistance still remains unanswered. In this study, a pair of lung cancer cell lines was established from one patient with squamous cell carcinoma of the lung, with one line being established before and one line after combination chemotherapy (cisplatin/ifosfamide/vindesine). Combination chemotherapy selected resistant EBC-2/R cells, which showed cross-resistance to 4-hydroxyifosfamide (3.2-fold), cisplatin (2.3-fold), and methotrexate (3.7-fold) and collateral sensitivity to vindesine (0.77-fold) compared with parent EBC-2 cells. EBC-2/R cells showed decrease in intracellular accumulation of cisplatin, increase in intracellular concentration of glutathione (GSH), and overexpression of multidrug resistance-associated protein (MRP) 3 when compared with EBC-2 cells. A single cycle of chemotherapy was not sufficient to select other mechanisms of drug resistance, such as multidrug resistance-1/P-glycoprotein, MRPs 1, 2, 4, and 5, lung resistance-related protein, metallothionein IIa,

glutathione S-transferase [pi], [gamma]-glutamylcysteine synthetase (light and heavy chain), and excision repair cross complementing 1. Sequentially we established two cell lines, which cell lines showed the differences of the cisplatin resistance, expression level of MRP3, intracellular GSH level and intracellular accumulation of cisplatin. A pair of cell lines will be useful to elucidate resistant mechanisms of cisplatin in heterogeneous lung cancer cells.

Koty, P. P., H. Zhang, et al. (1999). "Antisense bcl-2 treatment increases programmed cell death in non-small cell lung cancer cell lines." Lung Cancer **23**(2): 115.

<http://www.sciencedirect.com/science/article/B6T9C-3W19GP9-2/2/467e50c723c5e3b4732a532ffa01b9e6>

Programmed cell death (PCD) is a genetically regulated pathway that is altered in many cancers. This process is, in part, regulated by the ratio of PCD inducers (Bax) or inhibitors (Bcl-2). An abnormally high ratio of Bcl-2 to Bax prevents PCD, thus contributing to resistance to chemotherapeutic agents, many of which are capable of inducing PCD. Non-small cell lung cancer (NSCLC) cells demonstrate resistance to these PCD-inducing agents. If Bcl-2 prevents NSCLC cells from entering the PCD pathway, then reducing the amount of endogenous Bcl-2 product may allow these cells to spontaneously enter the PCD pathway. Our purpose was to determine the effects of bcl-2 antisense treatment on the levels of programmed cell death in NSCLC cells. First, we determined whether bcl-2 and bax mRNA were expressed in three morphologically distinct NSCLC cell lines: NCI-H226 (squamous), NCI-H358 (adenocarcinoma), and NCI-H596 (adenosquamous). Cells were then exposed to synthetic antisense bcl-2 oligonucleotide treatment, after which programmed cell death was determined, as evidenced by DNA fragmentation. Bcl-2 protein expression was detected immunohistochemically. All three NSCLC cell lines expressed both bcl-2 and bax mRNA and had functional PCD pathways. Synthetic antisense bcl-2 oligonucleotide treatment resulted in decreased Bcl-2 levels, reduced cell proliferation, decreased cell viability, and increased levels of spontaneous PCD. This represents the first evidence that decreasing Bcl-2 in three morphologically distinct NSCLC cell lines allows the cells to spontaneously enter a PCD pathway. It also indicates the potential therapeutic use of antisense bcl-2 in the treatment of NSCLC.

Merrick, D. T., J. Haney, et al. (2005). "Overexpression of vascular endothelial growth factor and its receptors in bronchial dysplasia demonstrated by quantitative RT-PCR analysis." Lung Cancer **48**(1): 31.

<http://www.sciencedirect.com/science/article/B6T9C-4DYW52N-1/2/56eba500fd3aabbf03160f605bf42fb84>

SummaryNeoangiogenesis is required for the growth of invasive lung carcinoma, however, the role of angiogenesis in the progression of premalignant changes to carcinoma of the lung is less clear. We have evaluated vascular endothelial growth factor (VEGF) expression and microvessel densities (MVDs) in 62 bronchoscopic biopsies from normal, reactive (basal cell hyperplasia (BCH)) and dysplastic bronchial epithelium and in tissue from twenty-seven invasive lung carcinomas in an effort to demonstrate angiogenic activity in these preneoplastic lesions and determine whether it is associated with increased bronchial epithelial VEGF expression. MVDs and VEGF RNA expression measured by quantitative RT-PCR were found to be elevated in comparison to normal bronchial tissue in bronchial dysplasias and invasive lung carcinomas but not in basal cell hyperplasias. Immunohistochemical (IHC) analyses revealed that expression of VEGF arose predominantly from bronchial epithelium. ELISA analysis of lung tumor tissue showed that elevated VEGF protein expression correlated with VEGF RNA levels ($r = 0.59$, $p = 0.004$). Increased expression of VEGF RNA was also found in histologically normal bronchial

mucosa from patients with either dysplasia at other sites or a history of heavy tobacco use suggesting a possible field effect in regard to the elaboration of VEGF. Furthermore, analysis of VEGF isoforms and VEGF receptors by semi-quantitative RT-PCR in dysplastic and invasive lesions revealed characteristic altered patterns of expression in dysplasia and early cancer as compared to normal tissue. These results indicate that angiogenesis develops early in lung carcinogenesis and is associated with overexpression of VEGF.

Oyanagi, H., K. Takenaka, et al. (2004). "Expression of LUN gene that encodes a novel RING finger protein is correlated with development and progression of non-small cell lung cancer." Lung Cancer **46**(1): 21.

<http://www.sciencedirect.com/science/article/B6T9C-4CGNT0T-1/2/777a75c799a0ee1355c8e552e63b0637>

LUN is a novel RING finger protein that is highly expressed in the lung and might be a transcriptional regulator of E-cadherin [J. Biol. Chem. 276 (2001) 14004]. It might be possible that LUN plays important roles in the development and progression of lung cancer through regulating expression of E-cadherin, but no clinical study on LUN expression has been reported. In the present study, we quantitatively examined gene expression of the LUN in surgical specimens resected from non-small cell lung cancer (NSCLC) patients. In normal lung tissues, the LUN gene expression was down-regulated in smokers (the mean LUN/GAPDH ratios, 0.222 for non-smokers and 0.144 for smokers; $P=0.030$). In addition, the mean LUN/GAPDH ratio in lung cancer tissues was significantly lower than that in normal lung tissues (0.072 versus 0.162; PLUN gene expression was slightly down-regulated along with progression of primary tumors, and strongly down-regulated along with nodal metastases (the mean LUN/GAPDH ratios, 0.091 for pN0, 0.073 for pN1, and 0.034 for pN2 diseases; $P=0.001$). These results suggested that LUN might play important roles in inhibition of nodal metastases as well as in suppression of smoking-related oncogenesis in NSCLC.

Seike, M., A. Gemma, et al. (2002). "The promoter region of the human BUBR1 gene and its expression analysis in lung cancer." Lung Cancer **38**(3): 229.

<http://www.sciencedirect.com/science/article/B6T9C-46WWBBY-B/2/96b7574d05564c6148d6af763269b85b>

Mitotic checkpoint impairment is present in human lung cancers with chromosomal instability (CIN). Spindle-checkpoint genes have been reported to be mutated in several human cancers, but these mutations are infrequent. Recent reports suggest that the hBUBR1 gene may play an important role in mitotic checkpoint control and in mitotic checkpoint impairment in human cancers. We analyzed the expression of hBUBR1 in lung cancer cell lines using real time quantitative RT-PCR. The expression of BUBR1 was found to be up-regulated in all of these cell lines. In addition, we cloned and characterized the promoter region of hBUBR1 and determined its genomic structure, which includes 23 exons. The open reading frame (ORF) of the hBUBR1 gene comprises exons 1 through 23. There are GC-rich regions located at the flanking region and about 150 bp upstream from exon 1. The promoter region (424 bp upstream from exon 1) showed promoter activity and includes multiple transcription factor consensus binding motifs, including those for Sp1, Nkx-2, CdxA, SRY, MyoD, Ik-2, HNF-3b, Staf, Oct-1, Nkx-2, v-Myb, and AML 1a. Multiple pathways leading to activation of those binding factors may contribute to hBUBR1 gene transcription. Knowledge of the genomic structure and the promoter region of the hBUBR1 gene will facilitate investigation of its role in mitotic checkpoint control and tumor progression in human cancers.

Tajima, K., Y. Obata, et al. (2003). "Expression of cancer/testis (CT) antigens in lung cancer." Lung Cancer **42**(1): 23.

<http://www.sciencedirect.com/science/article/B6T9C-48VTJFX-3/2/46b22f84e8b2a04c070e5efbe0f41f23>

Cancer/testis (CT) antigens are considered promising candidates for vaccine-based immunotherapy. The aim of this study was to investigate which CT antigens should be targeted in immunotherapy of Japanese lung cancer. To determine the expression of 12 CT antigens in Japanese primary lung cancers and cell lines, a reverse-transcription polymerase chain reaction (RT-PCR) analysis was performed. Among 46 primary lung cancers, high expression rates were found for MAGE-3 (41%, 19/46), and SSX-4 (35%, 16/46). A similar pattern of CT antigen expression was observed in 29 lung cancer cell lines. The expression frequency of a certain CT antigen, namely NY-ESO-1, in Japanese cases was drastically different from that in Caucasians. Polyvalent CT antigen vaccine may be effective to increase the number of lung cancer patients eligible for cancer-specific immunotherapy. Vaccination with MAGE-3 and SSX-1 would cover 57% of all patients, with three antigens, MAGE-3, SSX-1, and MAGE-4, would cover 65%, and with four antigens, MAGE-3, SSX-1, MAGE-4 and SSX-4, would cover 70%. Simultaneous expression of two or more CT antigens was observed in 25/46 (54%) primary lung cancers and 18/29 (62%) lung cancer cell lines. Polyvalent CT antigen vaccines may be also effective to reduce a chance of emergence of antigen loss variants, thus preventing tumors from escaping from the immune system. For this purpose, vaccination with combinations of MAGE-3 with MAGE-6, SSX-4, MAGE-1 or BAGE may be effective for a quarter of Japanese lung cancer patients. In addition, in silico surveys of dbEST database were used for identification of new CT antigens. We identified a novel gene, TES101RP, expressed only in some small cell lung cancers (SCLC) and in testis, as confirmed by RT-PCR analysis.

Tsai, Y.-Y., K. A. McGlynn, et al. (2003). "Genetic susceptibility and dietary patterns in lung cancer." Lung Cancer **41**(3): 269.

<http://www.sciencedirect.com/science/article/B6T9C-48V964D-1/2/9a761b0002ab1d455068a5ddf9e7b28e>

Cigarette smoking is the dominant risk factor for lung cancer, but only a minority of smokers ever develops tumors. Though genetic susceptibility is likely to explain some of the variability in risk, results from previous studies of genetic polymorphisms have been inconclusive. As diet may also affect the risk of lung cancer, it is possible that the degree of risk produced by smoking and genetic susceptibility varies, depending on diet. To assess this hypothesis, we conducted a case-control study to examine the effect of cigarette smoking, dietary patterns and variation in genes involved in phase II metabolism. A total of 254 individuals with lung cancer and 184 healthy controls were recruited for the study. To identify persons with similar dietary patterns, cluster analysis was performed using nutrient densities of four major dietary constituents: protein, carbohydrate, animal fat, and dietary fiber. Two groups of individuals were identified with distinct dietary patterns: (1) a group (n=2241) with a high intake of animal fat and protein and a low intake of carbohydrates and dietary fiber (the 'healthy' pattern) (2) a group (n=197) with a high intake of fiber and carbohydrate and a low intake of protein and animal fat (the 'unhealthy' pattern). On stratified analysis, several genotype/dietary pattern combinations were found to affect risk of lung cancer. Smokers who were not homozygous for the most common GSTP1 allele and had a healthy dietary pattern were at significantly lower risk than smokers who were homozygous for the GSTP1 common allele and who had an unhealthy dietary pattern (OR=0.16, 95%CI: 0.04-0.57). Among smokers who were GSTM1 null, persons with a healthy dietary pattern were at lower risk than persons with an unhealthy dietary pattern (OR: 0.46, 95%CI: 0.21-1.01). Among

smokers with an unhealthy dietary patterns, persons with a His/His genotype in the exon 3 polymorphism of EPHX1 were at significantly lower risk than persons who were not homozygous. These data suggest that dietary factors may affect the risk imposed by genetic susceptibility at detoxification loci. Adjustments using dietary pattern may be useful in elucidating the effects of polymorphisms in genes responsible for carcinogen metabolism.

Yang, H.-K., F. M. Scott, et al. (1998). "Correlation of expression of bombesin-like peptides and receptors with growth inhibition by an anti-bombesin antibody in small-cell lung cancer cell lines." Lung Cancer **21**(3): 165.

<http://www.sciencedirect.com/science/article/B6T9C-3TYVX73-2/2/db3e6557c518d36d35e95a50f6509d97>

The murine anti-bombesin monoclonal antibody, 2A11, has been demonstrated to inhibit growth of some small-cell lung cancer (SCLC) cells in nude mice xenografts and in a clinical trial. To determine if the expression of bombesin-like peptides (BLP) and their receptors (GRP-R and NMB-R) correlate with an in vitro response to 2A11, we measured these parameters in seven SCLC cell lines. Gastrin releasing peptide (GRP) mRNA was detected in three of seven cell lines (NCI-H69, NCI-H345, NCI-H510) and neuromedin B (NMB) mRNA was detected in all seven lines using an RNase protection assay (RPA). Immunoreactive BLP was detected in the cell pellets of all lines (range 0.11-59.90 pmol/mg protein) by a solid phase GRP radioimmunoassay (RIA) using ¹²⁵I-labeled 2A11. RPA detected GRP-receptor mRNA in two cell lines (NCI-H69 and NCI-H345) and NMB-receptor in three lines (NCI-H345, NCI-H510, and NCI-H660). Reverse transcriptase-PCR confirmed the presence of receptor mRNA in these lines and detected NMB-receptor in an additional three lines (NCI-H69, NCI-H82, and NCI-H187). Calcium mobilization in response to BLP stimulation was detected in the six cell lines expressing either GRP-R or NMB-R mRNA but not in NCI-N417, which had no detectable BLP-receptor. 2A11 (5 [μg/ml]) inhibited colony formation by 26-61% after 2 weeks in all cell lines except NCI-N417. Thus, growth inhibition by 2A11 requires the presence of at least one BLP-receptor. These findings may be useful in selecting patients with SCLC for treatment with 2A11.

Yano, T., K. Sugio, et al. (2000). "Direct IFN influence of interferon-[gamma] on proliferation and cell-surface antigen expression of non-small cell lung cancer cells." Lung Cancer **30**(3): 169.

<http://www.sciencedirect.com/science/article/B6T9C-41Y86HW-3/2/5aa88284cb7d8d2e94c14691fb729f7d>

In order to clarify the anti-tumor activity of IFN-[gamma], we investigated the direct IFN influence of IFN-[gamma] on both the growth and cell-surface antigen expression of tumor cells. In the present study, four human lung cancer cell lines were used; two squamous cell lines (QG-56, QG-95) and two adenocarcinoma cell lines (PC-9, PC-12). In all four tumor cell lines, mutations were detected in exon 7 of the p53 gene by a PCR-FSSCP analysis. The proliferation of QG-56 or QG-95 was inhibited by IFN-[gamma] in a dose-dependent manner with about 70% inhibition at 1000 JRU/ml while that of PC-9 was slightly inhibited with maximally 25% inhibition at 1000 JRU/ml. The growth of PC-12 was not inhibited at all. In QG-56, QG-95 and PC-9, the fraction of cells in G1 phase increased while the fractions of cells in both S and G2/M phases decreased after exposure to IFN-[gamma] (200 JRU/ml) for 72 h. The growth inhibition by long-term exposure to IFN-[gamma] was irreversible in QG-56. After culture in the presence of IFN-[gamma] (200 JRU/ml) for 14-16 days, tumor cells were examined for expression of various antigens, including HLA-class I, HLA-class II, and CEA. In all cell lines but PC-12, 100% of cells expressed HLA-class I after incubation with IFN-[gamma]. Both HLA-class II and CEA were also induced in those cell lines. The proportion of HLA-class II-positive cells or that of CEA-positive cells varied

among the cell lines. Of the three antigens, the degree of HLA-class II expression paralleled that of growth inhibition by IFN-[gamma] treatment. These results suggested that in various function of IFN-[gamma] against tumor cells, the anti-proliferative effect might be closely linked with the induction of HLA-class II probably through a similar posttranscriptional process, independent of the function of p53 gene.

Zhou, J. X., G. A. Niehans, et al. (2001). "Mechanisms of G1 checkpoint loss in resected early stage non-small cell lung cancer." Lung Cancer **32**(1): 27.

<http://www.sciencedirect.com/science/article/B6T9C-42MW5KD-5/2/780af80a7813174545e5a37f0469d857>

Loss of the G1 checkpoint appears to be extremely common among virtually all neoplasms. A variety of genetic and epigenetic mechanisms have been demonstrated to play significant roles in this process. In a consecutive series of early stage non-small cell lung cancer (NSCLC), we have established the loss of expression of the G1 Cdk inhibitors p15INK4b and p16INK4a by DNA methylation is very common (37%), and methylation of p16INK4a is tightly correlated with loss of expression of p16INK4a protein ($P=0.0018$). Furthermore, methylation of p15INK4b and p16INK4a appear inversely correlated, although methylation of p15INK4b is an infrequent event in this cohort (4%). Methylation was detected in all stages of NSCLC equally, and did not correlate with survival in these patients. Evidence for methylation was more frequent in squamous cell carcinomas in comparison to other tumor histologies ($P=0.0156$). In addition, over-expression of cyclin D1 was found to be tightly restricted ($P=0.0032$) to those tumors that had retained wild-type expression of pRB, and did not correlate with methylation or expression of p16INK4a gene product. Although loss of p16INK4a function remains tightly correlated with pRB expression, loss of other regulatory elements in NSCLC such as p53 mutation and cyclin D1 over-expression appear independent of loss of the p16INK4a gene product.

Mammalian Biology - Zeitschrift fur Saugetierkunde (1)

Lorenzini, R., R. Fico, et al. "Mitochondrial DNA evidence for a genetic distinction of the native red deer of Mesola, northern Italy, from the Alpine populations and the Sardinian subspecies." Mammalian Biology - Zeitschrift fur Saugetierkunde **In Press, Corrected Proof**

<http://www.sciencedirect.com/science/article/B7GX2-4FG898J-4/2/78df556a535b4f9660eab24cad6deaad>

Native red deer of Mesola Wood, northern Italy, were compared with the Sardinian subspecies and with some populations from the Italian Alps and Austria using the analysis of restriction fragment length polymorphism (RELP) of mitochondrial (mt) DNA segments. The results highlight the existence of four main genetic lineages, and provide evidence for a structuring of populations according to their geographic occurrence. Two mitochondrial lineages, although highly distantly related, are shared between the populations from the centre-eastern Alps of Italy and Austria, while the other two lineages characterize the Sardinian and Mesola red deer, respectively. The exclusive haplotype found in the Mesola population appears as being an offshot of one of the two main Alpine lineages, suggesting a presumed origin of these deer from a panmictic population which dwelt in mid-southern Europe, prior to the fragmentation of populations caused by human activities and manipulations. Considering their distinctiveness in morphologic and genetic traits,

as well as their historical background and biogeographical value, these native deer should be regarded as a national conservation priority. The Sardinian red deer is highly divergent from both Mesola and Alpine populations. However, the controversial question of the phylogeographic origin of this subspecies remains unresolved. The utility of RFLP analyses of mtDNA segments as a tool to discriminate among red deer populations as well as to develop effective strategies for their conservation and management. Zusammenfassung Mitochondrien-DNA-Daten zur genetischen Unterscheidung der autochthonen Rothirsche von Mesola, Norditalien, von jenen aus alpinen Populationen und von der Unterart auf Sardinien. Autochthone Rothirsche aus dem Mesola-Waldgebiet in Norditalien wurden mittels Restriktionsfragmenteangelpolymorphismen (RFLPs) von Abschnitten der mitochondrialen (mt)DNA mit Rotwild der sardischen Unterart und Tieren aus alpinen Populationen verglichen. Die Ergebnisse weisen auf die Existenz von vier genetischen Hauptlinien hin und belegen auch eine Strukturierung der Populationen gemäß ihrer geographischen Herkunft. Zwei entfernt verwandte mtDNA-Linien wurden in Beständen aus dem Zentral- und Ostalpenbereich von Italien und Österreich gefunden. Die beiden anderen Linien waren jeweils charakteristisch für Rotwild auf Sardinien und Rotwild in Mesola. Der exklusive Haplotyp der Mesola-Population scheint ein Abkommling einer der beiden alpinen Hauptlinien zu sein. Dies legt eine Abstammung der Mesola-Rothirsche von einer großräumigen, panmiktischen Population nahe, wie sie vor der anthropogen bedingten Fragmentierung und Isolation von Beständen im Bereich von Mittel- und Südeuropa existiert haben sollte. Sowohl nach der Eigenständigkeit in morphologischen und molekularen Merkmalen als auch im Hinblick auf die Bestandsgeschichte und den biogeographischen Wert sollte der letzten autochthonen Rotwildpopulation in Mesola eine nationale Priorität im Rahmen von Arterhaltungsprogrammen zugewilligt werden. Das sardinische Rotwild unterschied sich in hohem Maße von den alpinen Beständen und der Mesola-Population. Die phylogeographische Herkunft bleibt allerdings unklar. Die Brauchbarkeit von mtDNA-RFLPs zur Abgrenzung von Rothirschbeständen sowie zur Entwicklung von Arterhaltungs- und Management-Konzepten wird diskutiert.

Asuncion, L., B. Fogelgren, et al. (2001). "A novel human lysyl oxidase-like gene (LOXL4) on chromosome 10q24 has an altered scavenger receptor cysteine rich domain." Matrix Biology **20**(7): 487.

<http://www.sciencedirect.com/science/article/B6VPM-44B213D-9/2/64a14940501849e3d4af5a8c8e8d5050>

We have identified a novel 14-exon human lysyl oxidase-like gene, LOXL4, on chromosome 10q24. The cDNA and derived amino acid sequence of LOXL4 demonstrates a conserved C-terminal region including the characteristic copper-binding site, lysyl and tyrosyl residues and a cytokine receptor-like domain. One of the four N-terminal SRCR domains contains a 13 amino acid insertion encoded by a short exon not present within the closely homologous LOXL2 and LOXL3 genes. The 3.5-kb LOXL4 mRNA is present in pancreas and testis and at lower levels in several other tissues. Fibroblasts, smooth muscle and osteosarcoma (HOS) cells express LOXL4. No expression was detected in HCT-116 and DLD-1 colon, MCF-7 breast and DU-145 prostate cancer cell lines.

Azizan, A., J. U. Gaw, et al. (2000). "Chondromodulin I and pleiotrophin gene expression in bovine

cartilage and epiphysis." Matrix Biology **19**(6): 521.

<http://www.sciencedirect.com/science/article/B6VPM-41JTP8W-8/2/b7c91962c0e234eb8a9de9474362d01e>

Pleiotrophin and chondromodulin-I are low molecular weight proteins that are abundant (20 [mu]g/g tissue) in fetal cartilage and difficult to detect in adult cartilage. We characterized their gene and protein expression patterns to gain a better understanding of their roles in the regulation of limb development and growth. In order to compare and contrast the relative amounts of the respective mRNA species within the developing epiphysis, a competitive PCR assay was developed. The results showed that the mRNAs for both proteins were abundant in fetal cartilage and while present in adult cartilage, were at 20-60-fold lower levels. Northern blotting revealed gradients of mRNA for both of these proteins in growth plate cartilage, with the highest levels in the resting zone, and the lowest in the hypertrophic zone. In contrast to pleiotrophin, chondromodulin-1 is down-regulated by retinoic acid with a pattern of expression similar to collagen type II and link protein, and may play a more specific role than pleiotrophin in modulating the chondrocyte phenotype.

Botella, L. M., F. Sanz-Rodriguez, et al. (2004). "Lumican is down-regulated in cells expressing endoglin. Evidence for an inverse correlation between Endoglin and Lumican expression." Matrix Biology **22**(7): 561.

<http://www.sciencedirect.com/science/article/B6VPM-4BSW8KC-5/2/ce9b85ce637808f11e5fc5a99d1ca51a>

Endoglin (CD105) is a homodimeric membrane glycoprotein, which acts as a TGF-[beta] coreceptor in the vasculature and plays an important role in cardiovascular development and vascular remodelling. To isolate putative genes regulated by endoglin expression, a PCR-based RNA fingerprinting technique was carried out. Myoblasts stably transfected with endoglin showed a decrease in the expression of lumican both at the RNA and protein levels. Lumican is a proteoglycan of the extracellular matrix, belonging to the SLRP (Small Leucine-Rich Repeat Proteoglycans) family. Lumican down-regulation by endoglin appeared to be controlled, at least in part, at the transcriptional level, as indicated by RT-PCR, and transient transfection experiments using a lumican promoter reporter based vector. This inverse correlation between endoglin and lumican expression was substantiated by immunohistochemical staining of vessels from human tissues. Thus, cells belonging to the high endothelia, such as tonsil, express a large amount of endoglin, and the lumican content of their matrix is considerably reduced. Conversely, in resting endothelia, such as that of large vessels, the expression of endoglin is reduced whereas the amount of lumican is greatly increased. The inverse regulation in the expression of endoglin and lumican was also evident after TGF-[beta] treatments since endoglin was up-regulated, whereas lumican was down-regulated by this cytokine. This report describes for the first time a relationship between endoglin and lumican expression.

Clark, A. G., A. L. Rohrbach, et al. (2002). "The effects of ascorbic acid on cartilage metabolism in guinea pig articular cartilage explants." Matrix Biology **21**(2): 175.

<http://www.sciencedirect.com/science/article/B6VPM-44PVT88-1/2/1dab29c60aa570ed11d39fc00c27f674>

Ascorbic acid has been associated with the slowing of osteoarthritis progression in guinea pig and man. The goal of this study was to evaluate transcriptional and translational regulation of

cartilage matrix components by ascorbic acid. Guinea pig articular cartilage explants were grown in the presence of -ascorbic acid (-Asc), -isoascorbic acid (-Asc), sodium -ascorbate (Na -Asc), sodium -isoascorbate (Na -Asc), or ascorbyl-2-phosphate (A2P) to isolate and analyze the acidic and nutrient effects of ascorbic acid. Transcription of type II collagen, prolyl 4-hydroxylase (alpha subunit), and aggrecan increased in response to the antiscorbutic forms of ascorbic acid (-Asc, Na -Asc, and A2P) and was stereospecific to the -forms. Collagen and aggrecan synthesis also increased in response to the antiscorbutic forms but only in the absence of acidity. All ascorbic acid forms tended to increase oxidative damage over control. This was especially true for the non-nutrient -forms and the high dose -Asc. Finally, we investigated the ability of chondrocytes to express the newly described sodium-dependent vitamin C transporters (SVCTs). We identified transcripts for SVCT2 but not SVCT1 in guinea pig cartilage explants. This represents the first characterization of SVCTs in chondrocytes. This study confirms that ascorbic acid stimulates collagen synthesis and in addition modestly stimulates aggrecan synthesis. These effects are exerted at both transcriptional and post-transcriptional levels. The stereospecificity of these effects is consistent with chondrocyte expression of SVCT2, shown previously to transport -Asc more efficiently than -Asc. Therefore, this transporter may be the primary mechanism by which the -forms of ascorbic acid enter the chondrocyte to control matrix gene activity.

Ilic, M. Z., M. N. Vankemmelbeke, et al. (2000). "Bovine joint capsule and fibroblasts derived from joint capsule express aggrecanase activity." Matrix Biology **19**(3): 257.

<http://www.sciencedirect.com/science/article/B6VPM-40WDVPV-8/2/d2f1992f0b009049ad0caaa4773f63fc>

Bovine joint capsule was maintained in explant culture in the presence of bovine aggrecan monomer and it was shown that the aggrecan monomer was degraded. Amino-terminal sequence analysis of the resulting aggrecan core protein fragments revealed that the core protein was cleaved at five specific sites attributed to glutamyl endopeptidases referred to as aggrecanase activity. Fibroblast cultures were established from explant cultures of joint capsule and when these cells were exposed to aggrecan, cleavage of the core protein of aggrecan at the aggrecanase sites was observed. Inclusion of either retinoic acid or interleukin-1[alpha] in medium of either joint capsule explant cultures or fibroblast cultures did not increase the rate of cleavage of exogenous aggrecan present in the culture medium. When aggrecan monomer was incubated with conditioned medium from explant cultures of joint capsule maintained in medium, degradation could be detected after 10 min. After a 6-h incubation period the same fragments of aggrecan core protein were observed as those for tissue or cells incubated directly with aggrecan monomer. RT-PCR analysis of mRNA extracted from joint capsule fibroblasts showed that these cells express both aggrecanase-1 and -2 [ADAMTS-2 (Tang) and ADAMTS-5].

Kerkvliet, E. H. M., I. C. Jansen, et al. (2003). "Collagen type I, III and V differently modulate synthesis and activation of matrix metalloproteinases by cultured rabbit periosteal fibroblasts." Matrix Biology **22**(3): 217.

<http://www.sciencedirect.com/science/article/B6VPM-48N3JC5-2/2/09b5c676bc243cfa7f1c7add918040b1>

In the present study we investigated whether the collagen types I, III and V affect the activity of fibroblasts obtained from rabbit periosteum. The cells were cultured on plates either or not coated with different amounts of collagen type I, III or V and analyzed for their attachment, DNA synthesis and the expression and activity of matrix metalloproteinases (MMPs). Our data show that the three collagen types promoted attachment and spreading of the cells and stimulated DNA synthesis when used in relatively low concentrations. High concentrations of type V--but not of

type I or III--proved to inhibit thymidine incorporation. The expression and activity of matrix metalloproteinase 1 (MMP-1; interstitial collagenase) decreased under the influence of relatively low amounts of collagen (1-integrin or echistatin increased the level of MMP-1 but had no effect on MMP-2. All parameters tested were similarly affected by type I and III collagen, whereas the effect of type V was always less. We conclude that the collagen types I, III and V provide different sets of signals for fibroblasts that differently modulate their proliferation and MMP expression.

Konttinen, Y., S. Halinen, et al. (1998). "Matrix metalloproteinase (MMP)-9 type IV collagenase/gelatinase implicated in the pathogenesis of Sjogren's syndrome." Matrix Biology **17**(5): 335.

<http://www.sciencedirect.com/science/article/B6VPM-46YXFH8-9/2/20e3abd241f27ab103ecef45e8742c53>

Type IV collagenases/gelatinases (matrix metalloproteinases MMP-2 and MMP-9) in labial salivary glands (LSG) and saliva in Sjogren's syndrome (SS) and healthy controls were studied. Zymograms and Western blots disclosed that SS saliva contained 92/82 kD MMP-9/type IV collagenase duplex. Specific activity measurement disclosed 53.1 +/- 9.8 U/mg protein MMP-9 in SS compared to 16.5 +/- 2.6 U/mg in healthy controls (p = 0.01). MMP-2 did not differ between SS and controls. In SS salivary glands, MMP-2 and MMP-9 were also expressed, in addition to stromal fibroblasts and occasional infiltrating neutrophils, respectively, in acinar end piece cells. In addition, an effective proMMP-9 activator, human trypsin-2 (also known as tumor-associated trypsin-2 or TAT-2), was found in acinar end piece cells and in saliva. Interestingly, proteolytically processed MMP-9 was found in saliva (vide supra), and in vivo activated MMP-9 was significantly higher in SS than in controls (p = 0.002). LSGs, particularly in SS, were characterized ultrastructurally by areas containing small cytoplasmic vesicles in the basal parts of the epithelial cells associated with areas of disordered and thickened basal lamina. Based on our results, we conclude here that SS saliva contains increased concentrations of MMP-9, which is of glandular origin in part. Pro MMP-9 is to a large extent proteolytically activated. This is probably mediated by the most potent pro MMP-9 activator found in vivo thus far, namely trypsin-2. Therefore, the MMP-9/trypsin-2 cascade may be responsible for the increased remodelling and/or structural destruction of the basement membrane scaffolding in salivary glands in SS. Due to the role of basal lamina as an important molecular sieve and extracellular matrix-cell signal, these pathological changes may contribute to the pathogenesis of the syndrome.

Lorenzo, P., P. Aman, et al. (1999). "The human CILP gene: exon/intron organization and chromosomal mapping." Matrix Biology **18**(5): 445.

<http://www.sciencedirect.com/science/article/B6VPM-3Y3XR41-4/2/29b7d42200c08062426066ea150a7481>

The human cDNA for cartilage intermediate layer protein (CILP) codes for a larger precursor protein that consists of CILP and a homologue to porcine Nucleotide pyrophosphohydrolase (NTPPHase) [Lorenzo et al. 1998a. J. Biol. Chem. 273, 23469-23475]. The human gene has now been isolated and characterized. Southern blot analysis indicated a single copy of the CILP gene in the human genome. The gene spans approximately 15.3 kbp of genomic DNA, and is organized in nine exons. The 5' flanking region contains a putative promoter region with a TATA-like box localized from -29 to -23 bp upstream of the transcription start site. Analysis of the putative promoter region revealed potentially cis-regulatory eukaryotic elements such as GATA-1, MyoD, MZF1, and CdxA. The protein coding region begins in exon 2 with the putative signal peptide. CILP is encoded from exon 3 to exon 9. In addition, exon 9 also codes for the entire NTPPHase homologue and contains the 3' untranslated region of the gene. All the introns follow the 'gt-ag' rule, except the last intron, intron 8, that belongs to the minor class of pre-mRNA

introns that contain 'at-ac' at their 5' and 3' ends, respectively. The CILP gene was mapped to human chromosome 15q22.

Mates, L., E. Korpos, et al. (2002). "Comparative analysis of the mouse and human genes (Matn2 and MATN2) for matrilin-2, a filament-forming protein widely distributed in extracellular matrices." Matrix Biology **21**(2): 163.

<http://www.sciencedirect.com/science/article/B6VPM-44V2101-1/2/98d11c77df0765fe3767c67d2dd15ab0>

We previously identified matrilin-2 (MATN2), the largest member of the novel family of matrilins. These filament-forming adapter proteins expressed in a distinct, but partially overlapping, pattern in all tissues were implicated in the organization of the extracellular matrix. Matrilin-2 functions in a great variety of tissues. Here, we present the genomic organization of the highly conserved mouse and human MATN2 loci, which cover >100 kb and 167.167 kb genomic regions, respectively, and are composed of 19 exons. RT-PCR analysis revealed that alternative transcripts with identical protein coding regions are transcribed from two promoters in both species. The upstream, housekeeping type promoter is functional in all tissues and cell types tested. The activity of the downstream, TATA-like promoter preceded with putative motifs for the homeobox transcription factor PRRX2 is restricted to embryonic fibroblasts and certain cell lines. The oligomerization module is split by an U12-type AT-AC intron found in conserved position in all four matrilin genes. We assigned Matn2 to mouse chromosome 15, linked to Trhr and Sntb1 in a region syntenic to human chromosome 8q22-24.

Mates, L., C. Nicolae, et al. (2004). "Mice lacking the extracellular matrix adaptor protein matrilin-2 develop without obvious abnormalities." Matrix Biology **23**(3): 195.

<http://www.sciencedirect.com/science/article/B6VPM-4CPDFTP-5/2/e61391f65a1ed6f4c4943fa2fbebcb9>

Matrilins are putative adaptor proteins of the extracellular matrix (ECM) which can form both collagen-dependent and collagen-independent filamentous networks. While all known matrilins (matrilin-1, -2, -3, and -4) are expressed in cartilage, only matrilin-2 and matrilin-4 are abundant in non-skeletal tissues. To clarify the biological role of matrilin-2, we have developed a matrilin-2-deficient mouse strain. Matrilin-2 null mice show no gross abnormalities during embryonic or adult development, are fertile, and have a normal lifespan. Histological and ultrastructural analyses indicate apparently normal structure of all organs and tissues where matrilin-2 is expressed. Although matrilin-2 co-localizes with matrilin-4 in many tissues, Northern hybridization, semiquantitative RT-PCR, immunohistochemistry and biochemical analysis reveal no significant alteration in the steady-state level of matrilin-4 expression in homozygous mutant mice. Immunostaining of wild-type and mutant skin samples indicate no detectable differences in the expression and deposition of matrilin-2 binding partners including collagen I, laminin-nidogen complexes, fibrillin-2 and fibronectin. In addition, electron microscopy reveals an intact basement membrane at the epidermal-dermal junction and normal organization of the dermal collagen fibrils in mutant skin. These data suggest that either matrilin-2 and matrilin-2-mediated matrix-matrix interactions are dispensable for proper ECM assembly and function, or that they are efficiently compensated by other matrix components including wild-type levels of matrilin-4.

Sztrolovics, R., M. Van Der Rest, et al. (1994). "Identification of type I collagen gene polymorphisms:

Tolerance of sequence variation at an $[\alpha]2(I)$ Helix Y position." *Matrix Biology* **14**(1): 9.

<http://www.sciencedirect.com/science/article/B6VPM-47T8XVT-3/2/09c76fbc8fd8f57337779f517b6f9721>

This study has examined the frequency and distribution of polymorphisms in the type 1 collagen coding sequences. RNA from a group of human skin fibroblast cell lines, was analyzed by the chemical cleavage mismatch detection method using hydroxylamine, a reagent specific for C base mismatches, and overlapping cDNA probes covering the entire prepro $[\alpha]1(I)$ and prepro $[\alpha]2(I)$ coding regions. Mismatches were detected at only two nucleotide positions, one in each of the type I collagen sequences, suggesting that polymorphisms are relatively rare within these cDNAs. cDNA sequence analysis demonstrated that the prepro $[\alpha]1(I)$ mismatch, detected in only one cell line, was due to a sequence polymorphism involving the wobble position of the codon for arginine residue 59 within the amino-propeptide globular subdomain of the pro $[\alpha]1(I)$ chain and not resulting in a change in the polypeptide primary structure. In contrast, the prepro $[\alpha]2(I)$ mismatch, detected in 6 of the 16 cell lines, was shown to arise from a sequence polymorphism affecting the identity of Y-position residue 459 of the $[\alpha]2(I)$ triple helical domain, resulting in an alanine/proline dimorphism at this position. This study is the first to identify a type I collagen coding sequence polymorphism resulting in an alteration at the level of the amino acid sequence. The data suggest that at least some $[\alpha]1(I)$ and $[\alpha]2(I)$ helix Y positions may be tolerant of sequence variation, particularly if the replacing amino acid is proline, a residue involved in stabilizing the collagen triple helix.

Sztrolovicz, R., D. L. Rimoin, et al. (1994). "Single-strand conformation polymorphism analysis of human decorin, biglycan and fibromodulin cDNAs." *Matrix Biology* **14**(4): 307.

<http://www.sciencedirect.com/science/article/B6VPM-47GH9YC-5/2/6d785b226dfcb2d2c6a39f04cef75db0>

The coding regions of the human decorin, biglycan and fibromodulin cDNAs have been examined utilizing the method of single-strand conformation polymorphism analysis. Analysis of total RNA from a group of eight human skin fibroblast cell lines did not detect any sequence variations in the decorin cDNA. In contrast, the analysis detected three sequence variations in the biglycan cDNA and one in the fibromodulin cDNA from the same group of cell lines. For the biglycan cDNA, one variation involved a position in the 5'-untranslated region, while the other two affected the wobble bases of triplets encoding serine residues 10 and 143 of the mature core protein. For the fibromodulin cDNA, the variation involved the wobble position of the codon for glutamic acid residue 61 of the putative mature core protein. Single-strand conformation polymorphism analysis of these proteoglycan cDNAs was also applied to study patients exhibiting a variety of connective tissue pathologies, including chondrodysplasia punctata, Desbuquois syndrome, Dyggve-Melchior-Clausen syndrome, dyssegmental dysplasia, Ehlers-Danlos syndrome types I and III, Ellis van Creveld syndrome and thanatophoric dysplasia, though no additional sequence variations were detected.

Walker, L. C., M. A. Overstreet, et al. (2005). "Tissue-specific expression and regulation of the alternatively-spliced forms of lysyl hydroxylase 2 (LH2) in human kidney cells and skin fibroblasts." *Matrix Biology* **23**(8): 515.

<http://www.sciencedirect.com/science/article/B6VPM-4F0GR57-1/2/b93bfdf39d962c515c0244713b5e9d57>

Lysyl hydroxylases 1, 2, and 3 catalyse the hydroxylation of specific lysines in collagen. A small percentage of these hydroxylysine residues are precursors for the cross-link formation essential for the tensile strength of collagen. Lysyl hydroxylase 2 (LH2) exists as two alternatively-spliced forms; the long transcript (the major ubiquitously-expressed form) includes a 63 bp exon (13A) that is spliced out in the short form (expressed, together with the long form, in human kidney, spleen, liver, and placenta). This study shows that this alternative splicing event can be regulated by both cell density and cycloheximide (CHX). Although only the long form of LH2 is detected in untreated confluent human skin fibroblasts, after 24 h treatment with CHX the short LH2 transcript is also expressed. In kidney cells, in which both LH2 transcripts are equally expressed, the long LH2 transcript is significantly decreased after 24 h CHX treatment, whereas expression of the short transcript is slightly increased. This suggests that, in kidney cells, the splicing mechanism for the inclusion of exon 13A in LH2 requires a newly-synthesized protein factor that is suppressed by CHX, whereas, in skin fibroblasts in which levels of LH2 (long) are unaffected, CHX appears to suppress a factor that inhibits exclusion of exon 13A, thereby promoting expression of LH2 (short). As these alternate transcripts of LH2 may have specificity for hydroxylation of lysines in either telopeptide or helical collagen domains, their relative expression determines the type of cross-links formed, thereby affecting collagen strength. Therefore, any perturbation of the regulation of LH2 splicing could influence the stability of the extracellular matrix and contribute to specific connective tissue disorders.

Yao, L. Y., C. Moody, et al. (1994). "Identification of the proteoglycan versican in aorta and smooth muscle cells by DNA sequence analysis, in situ hybridization and immunohistochemistry." Matrix Biology **14**(3): 213.

<http://www.sciencedirect.com/science/article/B6VPM-47T2M7S-3/2/49c7a02a82d775d3b05fe4fea36e0b23>

Versican is a large chondroitin sulfate proteoglycan (CSPG) initially identified in cultured human fibroblasts. Previous studies have shown that there is a versican-like molecule in cultured monkey smooth muscle cells. In this study, we have cloned and sequenced the large CSPG from cultured monkey smooth muscle cells, fetal and juvenile monkey aorta, and human fetal aorta. The cDNA sequence from human fetal aorta is completely homologous to the human fibroblast versican. We obtained 2.5 kb of cDNA sequence from monkey aortic RNA and cultured monkey smooth muscle cell RNA. This sequence covers three distinct domains of versican (hyaluronic acid binding domain, glycosaminoglycan attachment domain and protein binding domain) and demonstrates over 90% homology to the human versican sequence. In situ hybridization histochemistry indicates that the versican RNA transcript is located in the epithelium throughout the tunica media of the aorta. Western blot analysis and immunohistochemistry also confirm the presence of versican in human and monkey aorta.

Yoon, S., H. Kuivaniemi, et al. (2002). "MMP13 promoter polymorphism is associated with atherosclerosis in the abdominal aorta of young black males." Matrix Biology **21**(6): 487.

<http://www.sciencedirect.com/science/article/B6VPM-470KM47-4/2/52aa52578ad341bd4c2a9e7b974c6211>

Previous studies suggested that remodeling of connective tissue is important in progression of atherosclerosis. We investigated the importance of matrix metalloproteinase 13 (MMP13), in the pathogenesis of atherosclerosis using 995 samples from the Pathobiological Determinants of Atherosclerosis in Youth collection in an association study. We identified two new MMP13 promoter polymorphisms. The genotype for one of the MMP13 polymorphisms was associated with fibrous plaque ($P=0.024$) in black males. Immunohistochemistry using antibodies for MMP13

showed that MMP13 is expressed in all layers of the aorta. In-vitro transfection experiments with reporter gene constructs and electrophoretic mobility-shift assays showed that the MMP13 polymorphism was a functional variant. MMP13 is therefore, a genetic risk factor for extent of fibrous plaque in the abdominal aorta in young black males. Elucidation of the currently unknown mechanism of the MMP13 polymorphism's action may provide for pharmacological intervention to reduce the severity of atherosclerotic changes in susceptible individuals.

Maturitas (5)

Arko, B., J. Prezelj, et al. "Association of the osteoprotegerin gene polymorphisms with bone mineral density in postmenopausal women." **Maturitas In Press, Corrected Proof**
<http://www.sciencedirect.com/science/article/B6T9F-4DF4D3G-1/2/0bed3adc5adb1ce693b7eda24819ba76>

Objectives: Osteoprotegerin (OPG) is a recently discovered member of the tumour necrosis factor receptor superfamily. It plays a crucial role in the control of bone resorption and its gene could therefore be a good candidate gene for osteoporosis. The aim of our work was to find polymorphisms in the OPG gene and to investigate their possible contribution to the genetic susceptibility to osteoporosis by testing for their association with bone mineral density (BMD). **Methods:** The whole OPG gene coding region was screened for the presence of polymorphisms in a group of 60 osteoporotic women by single-strand conformation polymorphism analysis (SSCP) approach. Association of the discovered polymorphisms with bone mineral density was investigated in 136 Slovenian postmenopausal women. **Results:** We detected eight OPG gene polymorphisms that were confirmed by direct DNA sequencing, deletion 4752_4753delCT and nucleotide substitutions 1181G > C, 1217C > T, 1284G > A, 4501C > T, 6893A > G, 6950A > C and 8738T > A. Nucleotide substitutions 1284G > A and 8738T > A have not been previously described. Polymorphisms 4752_4753delCT, 6893A > G and 6950A > C were in complete linkage and the same was true for 1217C > T and 4501C > T. The association with BMD was found only for polymorphism 1181G > C. Subjects with genotype 1181GG had significantly lower lumbar spine BMD than subjects displaying 1181GC. **Conclusions:** By our approach we detected eight polymorphisms in the OPG gene. According to our analysis polymorphism 1181G > C is associated with BMD and could therefore be considered as an element of genetic susceptibility to osteoporosis.

Chen, H.-Y., W.-C. Chen, et al. (2001). "Relation of the estrogen receptor [alpha] gene microsatellite polymorphism to bone mineral density and the susceptibility to osteoporosis in postmenopausal Chinese women in Taiwan." **Maturitas** **40**(2): 143.

<http://www.sciencedirect.com/science/article/B6T9F-44F6SB1-4/2/43554eca3c2a947ad222558cba6da90a>

Objective: Osteoporosis is a common disorder with a strong genetic component. Our aim was to investigate the correlation of the estrogen receptor [alpha] gene microsatellite polymorphism (TA dinucleotide repeat polymorphism 5' upstream of exon 1) with bone mineral density and their relationship to osteoporosis. **Methods:** We determined the estrogen receptor [alpha] gene microsatellite polymorphism using polymerase chain reaction-based microsatellite analysis in postmenopausal Chinese women in Taiwan. Bone mineral density of the lumbar spine and

proximal femur were measured using dual-energy X-ray absorptiometry. Results: The ER[alpha] genotype was classified into '12' through '27' according to the number of TA dinucleotide repeats they contained, as a 'signpost'. After adjustment for potential confounding factors including age, height, and weight, subjects with genotype 18+ (n=4) had lower bone mineral density values and a 54.5 times greater risk for osteoporosis when compared with subjects with genotype 18- (n=170) at the lumbar spine. This should be interpreted with caution because of the small number of subjects with the unfavorable genotype 18+. According to mean number of TA dinucleotide repeats, women with a high number of repeats (TA[gE]20) (n=38) had the lowest bone mineral density and a 6.1 times greater risk for osteoporosis than women with a low number of repeats (TA[lE]15) (n=61) at the femoral neck, after adjustment for potential confounding factors such as age, height, and weight. Conclusion: The present study suggests that the estrogen receptor [alpha] gene microsatellite polymorphism may be a candidate genetic marker for risk of osteoporosis in postmenopausal Chinese women in Taiwan.

Chen, H.-Y., W.-C. Chen, et al. (2003). "Interleukin-1[beta] and interleukin-1 receptor antagonist gene polymorphism in postmenopausal women: correlation to bone mineral density and susceptibility to osteoporosis." *Maturitas* **44**(1): 49.

<http://www.sciencedirect.com/science/article/B6T9F-47FDMSJ-2/2/b48f6a5d87faf376308ea0ba64999eb6>

Objective: Osteoporosis is a common disorder with a strong genetic component. Our aim was to investigate the correlations of the interleukin-1[beta] (IL-1[beta]) and interleukin-1 receptor antagonist (IL-1Ra) gene polymorphisms with bone mineral density (BMD) and their relationship to osteoporosis. Methods: The IL-1[beta] (promoter and exon 5) and IL-1Ra (intron 2) gene polymorphisms were determined using polymerase chain reaction. BMD of the lumbar spine and proximal femur were measured using dual-energy X-ray absorptiometry. Results: The prevalence of each genotype of the interleukin-1 related genes in the study population was: (1) 14% C/C, 71.5% C/T, and 14.5% T/T in IL-1[beta] promoter; (2) 95.3% E1/E1 and 4.7% E1/E2 in IL-1[beta] exon 5; (3) 92.4% I/I, 6.4% I/II, and 1.2% II/II in IL-1Ra intron 2. After adjustment for potential confounding factors such as age, height, weight, years since menopause, and daily calcium intake, subjects with genotype E1/E2 (n=8) in IL-1[beta] exon 5 had lower BMD values and a significantly greater risk for osteoporosis (OR 10.6, 95% CI 1.3-83.8) at the lumbar spine when compared with subjects with genotype E1/E1 (n=164) in IL-1[beta] exon 5. Conclusion: The Taq I IL-1[beta] exon 5 gene polymorphism is associated with reduced BMD and predisposes women to osteoporosis at the lumbar spine, but our results should be interpreted with caution because of the small number of subjects with the unfavorable E1/E2 genotype.

O'Toole, S. A., E. Dunn, et al. "Oestrogen regulated gene expression in normal and malignant endometrial tissue." *Maturitas In Press, Corrected Proof*

<http://www.sciencedirect.com/science/article/B6T9F-4D7K6Y9-1/2/c3bd3a050e898a062cb3eeed473d507b>

Objectives: The aim of this study was to examine the expression of oestrogen regulated genes in premenopausal and postmenopausal normal and malignant endometrial specimens. The molecular mechanisms and the role of these genes in endometrial carcinogenesis are poorly understood. Methods: Normal and malignant endometrial specimens were collected from patients undergoing hysterectomy. Real time TaqMan PCR was used to examine the mRNA expression levels of oestrogen receptor a (ERa) and b (ERb), progesterone receptor (PR), insulin like growth factor 1 (IGF-1) and vascular endothelial growth factor (VEGF). Results: Expression analysis was carried out on 60 patients. ERa was more predominantly expressed in the endometrial samples than ERb, 28% of the specimens did not express ER. Normal pre and postmenopausal tissue

expressed higher levels of ER α , PR and IGF-1 than malignant tissue. ER α and PR expression was significantly higher in the proliferative phase endometrium compared to the secretory phase (P Conclusions:ER α expression may play an important role in the regulation of PR in normal and malignant endometrium. Further work is needed to establish if IGF-1 plays a role in a subset of endometrial cancers and if isoforms of VEGF play a role in endometrial cancer.

Seidlova-Wuttke, D., H. Jarry, et al. "Effects of estradiol-17[beta], testosterone and a black cohosh preparation on bone and prostate in orchidectomized rats." *Maturitas In Press, Corrected Proof*
<http://www.sciencedirect.com/science/article/B6T9F-4D5JY24-4/2/4287cd3858fad5f64b24ec2b9ff3df39>

Estradiol (E2) and testosterone (T) effectively prevent orchidectomy (orx) induced osteoporosis. T, however, stimulates prostate proliferation which may lead to malignancy. We showed that a *Cimicifuga racemosa* (CR) preparation had bone-sparing effects without exerting estrogenic effects in the uterus. We studied therefore whether a CR preparation has also antiosteoporotic effects in orx rats substituted with E2, T or CR via pelleted food over a period of 3 months. Average daily intake per animal was: T: 25 mg; E2: 0.325 mg, CR low dose: 33 mg; CR high dose: 133 mg. E2, T and CR at the high dose partially prevented development of osteoporosis as measured by quantitative computer tomography in the metaphysis of the tibia. E2, but not T or CR reduced serum osteocalcin and the metabolic products of collagen-1[α 1]. Gene expression of collagen-1[α 1] and tartrate-resistant acid phosphatase was decreased by E2 and the higher dose of the CR extract but increased in the T-treated animals. In the prostate T inhibited androgen receptor, estrogen receptor [α] and insulin-like growth factor-1 gene expression but stimulated the expression of the ER[beta] gene. These effects were not shared by E2 or both doses of the CR extract. It is concluded that E2, T and CR exert antiosteoporotic effects in the metaphysis of the tibia of orx rats. T has profound effects in the prostate which were not seen in the E2- and CR-treated animals. Therefore, the *Cimicifuga racemosa* extract BNO 1055 may be useful to prevent osteoporosis in aged male patients with reduced testosterone production.

Mechanisms of Ageing and Development (12)

Bloom, E. T., W. C. Thompson, et al. (1995). "Differential effects of interleukin-12 treatment on gene expression by allostimulated T cells from young and aged mice." *Mechanisms of Ageing and Development* **85**(2-3): 109.

<http://www.sciencedirect.com/science/article/B6T31-4031VR5-5/2/288ee226303e28d562da033ec310a6cd>

Alloantigen stimulation was used to examine the effect of interleukin (IL-12) treatment of stimulated cells from young and aged mice on the expression of mRNAs for perforin and granzyme B, two proteins known to be intimately involved in an important lytic pathway used by CTL, and mRNA for interferon (IFN)-[γ], production of which is highly stimulated by IL-12. As reported previously, IL-12 augmented the lytic activity by cells from both young and aged mice, although the relative increase was greater for the latter. The mRNAs encoding perforin and granzyme B were both marginally enhanced at early time points (for cells from young mice) or throughout the stimulation (for cells from aged mice) following allo-stimulation in the presence of

IL-12. The levels of augmentation of these mRNAs was consistent with the augmentation of lytic activity. In contrast, mRNA encoding IFN-[gamma] was markedly enhanced throughout stimulation in cells from animals of both age groups, corresponding to the more substantial increase in interferon protein in response to IL-12.

Frasca, D., S. Pucci, et al. (1997). "Regulation of cytokine production in aging: use of recombinant cytokines to upregulate mitogen-stimulated spleen cells." Mechanisms of Ageing and Development **93**(1-3): 157.

<http://www.sciencedirect.com/science/article/B6T31-3RM6SHJ-J/2/34dfc926c705218b8370a1d5e4cf7d63>

We investigated the production of IL-2 and IFN-[gamma] (Th1 type) and IL-4 (Th2 type) cytokines by mitogen-activated spleen cells from young, adult and old mice. Cytokine production was evaluated in culture supernatants by CTLL proliferation (IL-2), ELISA (IFN-[gamma]), CT4.S proliferation (IL-4) and in mRNA extracted from activated CD4+ cells by RT-PCR (IL-2, IFN-[gamma] and IL-4). Results show that the production of IL-2, as protein and mRNA, is profoundly depressed by aging, whereas that of IFN-[gamma], as protein and mRNA, firstly declines and then increases with age. The production of IL-4, as protein, monotonically declines with aging whereas, as mRNA, firstly decreases and then increases above the level in young mice. Spleen cells in culture were also incubated with mitogens and with a recombinant cytokine (IL-1[beta], IL-2, IL-3, IL-4, IL-12 or IFN-[gamma]) at various concentrations. It was found that recombinant cytokines by and large enhance cytokine production when the level induced by mitogens only is low. This conclusion applies to IL-2 and IFN-[gamma] production as protein and mRNA. The addition of recombinant cytokines also increases the production of IL-4 at the protein level in spleen cells from old mice but, at the mRNA level, only in spleen cells from young mice. This finding suggests age-related changes in IL-4-specific mRNA transcription rate and post-transcriptional half-life as well as translation kinetics.

Goyns, M. H., M. A. Charlton, et al. (1998). "Differential display analysis of gene expression indicates that age-related changes are restricted to a small cohort of genes." Mechanisms of Ageing and Development **101**(1-2): 73.

<http://www.sciencedirect.com/science/article/B6T31-3SY3GPD-6/2/883d564bc38f272e91bf524c8a5bf326>

It is clear that there is a genetic component associated with the ageing process. Although evolutionary theory has suggested that the activity of certain genes may facilitate ageing by favouring resource utilisation by the germ cells at the expense of somatic cells, there is reason to believe that the senescent phenotype, which is the endpoint of the ageing process, may be due to alterations in the levels of expression of other genes. To investigate this situation we have used the differential display technique to survey gene expression during ageing of the rat brain, heart and liver. By optimising this technique it is possible to identify up to 10000-14000 PCR products, which represent genes expressed in the tissue under study. Interestingly, only a relatively small cohort ([ap]2%) of these genes appear to show significant changes in their levels of expression during ageing. Characterisation of the latter has so far revealed certain genes, such as glial fibrillary acidic protein, which are associated with the senescent phenotype. It has also revealed that the level of fos, a component of the AP-1 transcription factor, decreases with age, which has implications for AP-1 regulated genes. The differential display technique has also revealed an increase in mitochondrial RNA during ageing of the heart, which may be due to a gene dosage effect caused by the presence of increased numbers of mitochondrial genomes in myocytes in old age. The differential display technique therefore appears to offer a powerful tool for identifying

genes which contribute to the emergence of a senescent phenotype.

Hardouin, S., F. Bourgeois, et al. (1998). "[beta]-Adrenergic and muscarinic receptor mRNA accumulation in the sinoatrial node area of adult and senescent rat hearts." Mechanisms of Ageing and Development **100**(3): 277.

<http://www.sciencedirect.com/science/article/B6T31-3SBVW1W-7/2/a25302ff79b2094b024744160b6d7978>

The sinoatrial (SA) node is the cardiac pacemaker and changes in its adrenergic-muscarinic phenotype have been postulated as a determinant of age-associated modifications in heart rate variability. To address this question, right atria were microdissected, the SA node area was identified by acetylcholinesterase staining, and, using a RT-PCR method, the accumulation of mRNA molecules encoding [beta]1- and [beta]2-adrenergic ([beta]1- and [beta]2-AR) and muscarinic (M2-R) receptor was quantified to define the proportion between [beta]-AR and M2-R mRNAs within the sinoatrial area of adult (3 months) and senescent (24 months) individual rat hearts. In adult hearts, the highest M2-R/[beta]-AR mRNA ratio was observed within the sinoatrial area compared with adjacent atrial myocardium, while in the senescent hearts, no difference was observed between sinoatrial and adjacent areas. This change was specific of the sinoatrial area since adult and senescent whole atrial or ventricular myocardium did not differ in their M2-R/[beta]-AR mRNA ratio, and was associated with a fragmentation of acetylcholinesterase staining of the senescent SA node. Quantitative changes in the expression of genes encoding proteins involved in heart rate regulation specifically affect the sinoatrial area of the senescent heart.

Iida, R., T. Yasuda, et al. (2000). "Age-related changes of gene expression in mouse kidney: fluorescence differential display -- PCR analyses." Mechanisms of Ageing and Development **113**(2): 135.

<http://www.sciencedirect.com/science/article/B6T31-3YGD54P-5/2/264dc89b51bc9e2fe07cbb458a3009bd>

We used a fluorescence differential display -- PCR (FDD-PCR) technique to analyze the genes expressed in mouse kidneys collected at nine different developmental stages ranging from 3 days to 15 months after birth. We found ten genes that were age-dependent and differentially-expressed in the kidneys during our experimental period. We confirmed by comparative RT-PCR that of the ten cDNAs, seven showed reproducible age-dependent expression. Four of the nucleotide sequences of these cDNA clones, had high homology with known genes (fibronectin, soluble guanylyl cyclase [alpha]-1 subunit, cytosolic aldehyde dehydrogenase and mitochondrial DNA), and three with expressed sequence tags of unknown genes. The FDD-PCR method was very useful for detecting new age-related genes expressed differentially in the mouse kidney.

Janapati, V., A. Wu, et al. (1995). "Post-transcriptional regulation of the Na⁺/Ca²⁺ exchanger in aging rat heart." Mechanisms of Ageing and Development **84**(3): 195.

<http://www.sciencedirect.com/science/article/B6T31-4031SF0-B/2/58f921810951f50305607fef030aa006>

Altered calcium homeostasis in the senescent heart appears to be the result, at least in part, of decreased Na⁺/Ca²⁺ exchange activity. To further investigate the basis of the decrease in

Na⁺/Ca²⁺ exchange activity, Na⁺/Ca²⁺ exchanger gene expression in the heart was compared in 3 and 24 month old male Fischer 344 rats. Sarcolemmal vesicles prepared from left ventricle and septum showed reduced Na⁺-dependent Ca²⁺ uptake in 24 month old animals when compared to 3 month old animals (0.156 ± 0.005 and 0.135 ± 0.008 nmol Ca²⁺/mg/10 s; mean ± S.E. for 3 month and 24 month old animals, respectively). Western analysis showed immunodetectable Na⁺/Ca²⁺ exchanger protein levels were decreased by 19% in 24 month old animals when compared to 3 month old animals. Poly(A⁺) RNA was purified from left and right ventricle and left and right atria and subjected to Northern analysis using digoxin labeled cDNA probes for the Na⁺/Ca²⁺ exchanger and actin. The Na⁺/Ca²⁺ exchanger probe labeled a 7 kb message in both ventricle and atria, while the actin probe labeled both [β]-actin (2.2 kb) and [α]-actin (1.4 kb). The steady state level of expression of Na⁺/Ca²⁺ exchanger Poly(A⁺) RNA when normalized to [β]-actin, was similar when ventricle and atria were compared. There were no observable differences in Na⁺/Ca²⁺ exchanger or [α]-actin Poly(A⁺) RNA steady state levels when comparing 3 and 24 month old animals. The results suggest that reduced Na⁺/Ca²⁺ exchange activity in the left ventricle of 24 month old animals was most likely the result of post-transcriptional modification of the protein that was detectable by Western analysis.

Jung, K.-Y., D. Dean, et al. (2004). "Loss of N-cadherin and [α]-catenin in the proximal tubules of aging male Fischer 344 rats." Mechanisms of Ageing and Development **125**(6): 445.

<http://www.sciencedirect.com/science/article/B6T31-4C8DD85-1/2/f64e1fcd3b3c2f00a4b40a6ae1b44c26>

Aging is associated with a loss of renal reserve, and increased sensitivity to either xenobiotic or physiologic insult. Given the critical role of the cadherin/catenin complex in establishing and maintaining the integrity and polarity of tubular epithelial cells, it was hypothesized that aging was associated with alterations in renal cadherin/catenin complexes. Histological assessment of aged (24 months) kidneys harvested from male Fischer 344 rats demonstrates mild degeneration of proximal tubules, multifocal chronic lymphocytic infiltration, moderate development of protein casts inside tubules, and tubular dilatation or degeneration. Western blot analysis revealed that N-cadherin protein expression is not constant over 24 months. N-cadherin expression increased from 4 to 9 months, with peak levels at 9 and 13 months. A decrease in expression was seen at 19 months and an almost complete loss of expression was seen at 24 months. In contrast, the expression of E- and Ksp-cadherin was constant over 24 months. A loss of [α]-catenin was seen at 19 and 24 months in the absence of changes in [β]-, [γ]-, and p120-catenin. This pattern of N-cadherin expression (increase followed by decrease) was confirmed by real-time PCR analysis, which demonstrated a similar pattern as the Western blot, suggesting that the loss of N-cadherin protein was due to decreased gene expression. The loss of N-cadherin was specific for the kidney, as no changes in N-cadherin expression in the liver, brain, or testes were seen during aging. The conclusion that loss of N-cadherin expression is a critical component of the renal dysfunction associated with aging is supported by the finding that caloric restriction attenuates the loss of N-cadherin, as well as the finding that a significant loss of N-cadherin is seen in the kidneys of ZDF x SHHF rats, a genetic model of end-stage renal disease. Cadherin and catenin expression was further analyzed by immunofluorescence. A significant loss of staining of both N-cadherin and [α]-catenin was seen in the proximal tubules of rats at 24 months. Interestingly, this corresponded with delocalization of the [α]-1 subunit of the Na⁺K⁺-ATPase, i.e. aberrant staining on cell-cell borders and some indication of apical staining in proximal tubules. Taken together, these data suggest that aging is associated with decreased expression of N-cadherin and [α]-catenin and is associated with a loss of cell polarity.

Kuehl-Kovarik, M. C., K. R. Magnusson, et al. (2000). "Electrophysiological analysis of NMDA receptor subunit changes in the aging mouse cortex." Mechanisms of Ageing and Development **115**(1-2):

<http://www.sciencedirect.com/science/article/B6T31-40GJ21G-3/2/f86c4ba64eed016f60591936696026a9>

NMDA receptors play an important role in memory processes and plasticity in the brain. We have previously demonstrated a significant decrease in NMDAR[ϵ]2 subunit mRNA and protein with increasing age in the C57Bl/6 mouse frontal cortex. In the present study, two-electrode voltage clamp electrophysiology on *Xenopus* oocytes injected with total RNA harvested from the frontal cortex of young and old C57Bl mice was used to detect changes in receptor composition during aging. Ifenprodil concentration-response curves, magnesium current-voltage curves, and single channel conductances were determined for native receptors. In addition, ifenprodil and magnesium curves were generated for recombinant NMDA receptors of varying subunit ratios. Ifenprodil dose-response curves for all receptors were biphasic. The low affinity component of the curve increased slightly with age, while the high affinity population decreased, mimicking recombinant receptors with decreasing levels of [ϵ]2. A decrease in maximal current was also observed in aged animals with decreased levels of [ϵ]2, although single channel conductances were identical between young and old mice. In addition, an increase in sensitivity to magnesium was observed for receptors from older animals. Results are consistent with the interpretation that the [ϵ]2 subunit is reduced in older mouse frontal cortex. A change in NMDA receptor subunit composition could influence memory processes during aging.

Nemani, M., M. Sahbatou, et al. (2000). "The efficiency of genetic analysis of DNA from aged siblings to detect chromosomal regions implicated in longevity." Mechanisms of Ageing and Development **119**(1-2): 25.

<http://www.sciencedirect.com/science/article/B6T31-41F62WP-4/2/dbd2b07103f96fe873b2355545c0b2f7>

Studies of the frequencies of different alleles in young adults and aged individuals have implicated several genes, such as ApoE and ACE, in longevity. However such association studies can easily give rise to spurious results through unsuspected population subdivision, and an approach making use of genetic relationships among relatives is desirable. We have studied the effectiveness of non-parametric genetic analysis to detect different types of loci affecting longevity. The non-parametric method has high statistical power to detect infrequent recessive alleles that are required for, or significantly increase the probability of, survival to advanced age. Statistical power is reduced if a proportion of carriers of the alternative allele is allowed to survive. The method is least effective in detecting alleles that occur at low frequency in young individuals and that subsequently experience high mortality, as is the case for carriers of the [ϵ]4 allele of ApoE. Genotyping errors will also reduce the value of the NPL statistic in a linear fashion with the error rate and the number of loci genotyped. We have also used the method to analyse genotypes of seven highly polymorphic markers near the ApoE gene in a sample of 188 sibships of nonagenarians and centenarians (n=434) and their children (n=124), however no excess sharing of alleles was detected.

O'Brien, M. E., S. Jensen, et al. (1998). "Hutchinson-Gilford progeria: faithful DNA maintenance, inheritance and allelic transcription of [beta](1-4) galactosyltransferase." Mechanisms of Ageing and Development **101**(1-2): 43.

<http://www.sciencedirect.com/science/article/B6T31-3SY3GPD-4/2/a543014d6fe9a83108ad0b1174a4aa5e>

Hutchinson-Gilford progeria syndrome (HGPS) is a fatal segmental aging disorder affecting children. There is a paucity of prior data at the nucleotide level on DNA maintenance in HGPS. We have examined the specific nucleotide sequences and production of allelic transcripts from the locus GGTB2 encoding [beta](1-4) galactosyltransferase. Quantitative Northern blots of mRNA from HGPS and control fibroblasts indicated identical mature [beta](1-4) galactosyltransferase transcript sizes and amounts, regardless of their altered glycosylation status. DNA sequencing of cDNA derived from HGPS [beta](1-4) galactosyltransferase mRNA populations confirmed the encoded amino acid sequence was unaffected. Population studies of 41 unrelated individuals provided allelic frequency estimates for a novel FokI polymorphism, which was identified in two of six progeria cell strains. The polymorphism was faithfully inherited in a progeria pedigree in a Mendelian manner. Furthermore, the polymorphism provided direct evidence through sequencing of reverse transcription polymerase chain reaction products that both alleles were transcribed and generated mature mRNA. Any defects in transcripts were below detectable levels over the lengths of coding sequences examined, despite multiple replication events from conception leading to the production and maintenance of patient-derived cells. These results indicate faithful transcription in HGPS.

Ohzeki, K., M. Yamaguchi, et al. (1999). "Effect of cellular aging on the induction of cyclooxygenase-2 by mechanical stress in human periodontal ligament cells." Mechanisms of Ageing and Development **108**(2): 151.

<http://www.sciencedirect.com/science/article/B6T31-3WHKRFH-5/2/9d39ccaac1423ba891584062951de9a3>

The production of prostaglandin (PGE₂) in human periodontal ligament fibroblast (hPLF) cells is increased by mechanical stress, however, the age-related changes in the susceptibility of hPLF cells in response to mechanical stress remain unclear. The purpose of this study was to examine the influence of in vitro cellular aging on PGE₂ production and the gene expression of cyclooxygenase (COX) in mechanically stressed hPLF cells. In vitro cellular aged hPLF cells were prepared by sequential subcultivations of hPLF cells from young healthy periodontal ligaments. In vitro cellular aged hPLF cells produced a significantly higher amount of PGE₂, as compared with young hPLF cells, when the cells were exposed to cyclic tension force in a time- and magnitude-dependent manner. The COX-2 mRNA level in aged cells was higher than that in young cells, whereas COX-1 mRNA remained unchanged. Since PGE₂ from hPLF cells was stimulated by in vitro aging as presented here, aging of hPLF cells may affect the severity of inflammation and bone resorption in the aged through the production of a large amount of PGE₂ in response to an excessive force such as a traumatic occlusion.

Shimizu, Y., J. Suzuki, et al. (2003). "In vitro aging of macaque adherent cells: similar pattern of cellular aging between human and macaque." Mechanisms of Ageing and Development **124**(2): 237.

<http://www.sciencedirect.com/science/article/B6T31-47F750C-1/2/fabed59b1c3d8a624db946ccc0d5bb52>

To explore new models for human cellular aging as well as to evaluate aging of the macaques, profiles of cellular aging in macaques were studied. Adherent cells were obtained from five Japanese macaques (*Macaca fuscata*), 14 long-tailed macaques (*Macaca fascicularis*), two bonnet monkeys (*Macaca radiata*) and a rhesus monkey (*Macaca mulatta*). A total of 35 cultures were performed and cell morphology, doubling time, telomere length and telomerase activity were studied. They were classified into three groups; group I: cell strains with a definite replicative life-span (<41 PDLs) (presence of M1), group II: cell strains with a limited extension of replicative life-span (79-106 PDLs) with p53 mutation(s) (presence of M2), and group III: a cell strain with an

indefinite replicative life-span (>150 PDLs) with characteristics of transformation. Except for the last group, telomerase activity was not observed. Macaque cells demonstrated three chronological patterns comprising both human and rodent patterns, however, presence of the two limits of proliferation in vitro grants macaque cells to be more appropriate than rodents in both studying human aging and oncogenesis.

Mechanisms of Development (17)

Bragg, A. D., H. L. Moses, et al. (2001). "Signaling to the epithelium is not sufficient to mediate all of the effects of transforming growth factor [beta] and bone morphogenetic protein 4 on murine embryonic lung development." Mechanisms of Development **109**(1): 13.

<http://www.sciencedirect.com/science/article/B6T9H-43VSC56-1/2/4ed51d02554b38d46c8b5c9ebc938efd>

Many studies have suggested that transforming growth factor [beta] (TGF-[beta]) and bone morphogenetic protein 4 (Bmp4) regulate early development of the lung. In this study, administration of growth factors directly into the lumen of lungs grown in organ culture was used to limit their activity to the epithelium and test the hypothesis that signaling to the epithelium is sufficient to mediate the known effects of TGF-[beta] and BMP-4 on early lung development. Addition of TGF-[beta]1, [beta]2, or [beta]3 to the medium surrounding lungs grown in organ culture resulted in decreased branching, reduced cell proliferation, accumulation of [alpha]-smooth muscle actin protein ([alpha]-SMA) in the mesenchyme, and decreased expression of a marker for respiratory epithelium, surfactant protein-C (Sp-C). When TGF-[beta]1 was restricted to the epithelium, accumulation of [alpha]-SMA and inhibition of Sp-C expression were not observed but branching and proliferation were inhibited. In contrast, branching was not inhibited in lungs where TGF-[beta]2 or TGF-[beta]3 were restricted to the epithelium suggesting differences in the mechanism of signaling by TGF-[beta]1, TGF-[beta]2 or TGF-[beta]3 in lung. Addition of Bmp4 to the medium surrounding lungs grown in organ culture stimulated cell proliferation and branching morphogenesis; however, direct injection of Bmp4 into the lung lumen had no effect on proliferation or branching. Based on these data and data from mesenchyme-free cultures, we propose that the mesenchyme influences growth factor signaling in the lung.

Groger, H., P. Callaerts, et al. (2000). "Characterization and expression analysis of an ancestor-type Pax gene in the hydrozoan jellyfish *Podocoryne carnea*." Mechanisms of Development **94**(1-2): 157.

<http://www.sciencedirect.com/science/article/B6T9H-40D61D7-G/2/244cdf18fa8047c379b96ea5bc8337e7>

We characterized a Pax gene from the hydrozoan *Podocoryne carnea*. It is most similar to cnidarian Pax-B genes and encodes a paired domain, a homeodomain and an octapeptide. Expression analysis demonstrates the presence of Pax-B transcripts in eggs, the ectoderm of the planula larva and in a few scattered cells in the apical polyp ectoderm. In developing and mature medusae, Pax-B is localized in particular endodermal cells, oriented toward the outside. Pax-B is not expressed in muscle cells. However, if isolated striated muscle tissue is activated for transdifferentiation, the gene is expressed within 1 h, before new cell types, such as smooth muscle and nerve cells, have formed. The expression data indicate that Pax-B is involved in

nerve cell differentiation.

Hinman, V. F., A. T. Nguyen, et al. (2003). "Expression and function of a starfish Otx ortholog, AmOtx: a conserved role for Otx proteins in endoderm development that predates divergence of the eleutherozoa." Mechanisms of Development **120**(10): 1165.

<http://www.sciencedirect.com/science/article/B6T9H-49H1FN9-1/2/4f079e3f8aa2d08249e03ff39ce3f7da>

The sea urchin orthodenticle (Otx)-related transcription factor is an early activator of other endomesodermally expressed transcription factors. Its normal function is required for the development of the archenteron and to lock cells into endomesodermal fate. To determine if this is a basal Otx function in echinoderms we have studied the role of an Otx ortholog in a starfish, *Asterina miniata*. The patterns of AmOtx expression are found to be similar, in many details, to those reported for other indirectly developing echinoderms and hemichordates, suggestive of a conserved function both in endoderm development and ciliary band formation in these two phyla. When downstream targets of the AmOtx protein are suppressed using a dominant engrailed repressor strategy, embryos fail to develop the endodermal component of the archenteron, though initial phases of mesoderm development proceed normally. The function of Otx proteins in endodermal development at least predated the evolution of the free-living echinoderms (Eleutherozoa).

Hodges, D. and S. I. Bernstein (1992). "Suboptimal 5' and 3' splice sites regulate alternative splicing of *Drosophila melanogaster* myosin heavy chain transcripts in vitro." Mechanisms of Development **37**(3): 127.

<http://www.sciencedirect.com/science/article/B6T9H-491TYSM-4/2/f6e5e1416a117f6511bc61acb0534f85>

Using a *Drosophila* cell-free system, we have analyzed the regulation of alternative splicing of *Drosophila* muscle myosin heavy chain (MHC) transcripts. Splicing of MHC 3' end transcripts results in exclusion of adult-specific alternative exon 18, as is observed in embryonic and larval muscle in vivo. Mutations that strengthen either the 5' or the 3' splice sites of exon 18 do not promote inclusion of this exon. However, strengthening both splice junctions results in efficient removal of both introns and completely inhibits skip splicing. Our data suggest that the affinity of exons 17 and 19, as well as failure of constitutive splicing factors to recognize exon 18 splice sites, causes the exclusion of exon 18 in wild-type transcripts processed in vitro.

Joos, T. O., R. David, et al. (1996). "xGCNF, a nuclear orphan receptor is expressed during neurulation in *Xenopus laevis*." Mechanisms of Development **60**(1): 45.

<http://www.sciencedirect.com/science/article/B6T9H-3W3158V-4/2/1689d08366ea0ab755840bcdd59b8794>

Nuclear orphan receptors are DNA binding proteins that share the domain structure of the nuclear hormone receptor superfamily, although ligands are unknown. We have identified an orphan receptor in *Xenopus laevis* and named it xGCNF based on its high degree of sequence homology to the previously described murine germ cell nuclear factor (mGCNF). In gel-electrophoresis mobility shift analysis experiments in vitro translated xGCNF and mGCNF proteins both bind

specifically as homodimers to the same response element, a direct repeat of the half-site consensus AGGTCA with zero spacing (DR0). Transcripts of xGCNF are found in oocytes and in much smaller amounts in the testes. In developmental Northern blots and RNase protection using RNA from different embryonic stages, zygotic expression of xGCNF peaks at midneurula. From late gastrula to midneurula stages, an anterior to posterior concentration gradient of the RNA was observed in whole mount in situ analysis. This antero-posterior gradient of expression was also observed in exogastrulae, both in the ectoderm and mesoderm. In the midneurula embryo, the mRNA was predominantly found in the neural plate and neural crest. Transcription of xGCNF in animal cap explants occurred independent of mesoderm induction.

Krovel, A. V. and L. C. Olsen (2002). "Expression of a vas:EGFP transgene in primordial germ cells of the zebrafish." Mechanisms of Development **116**(1-2): 141.

<http://www.sciencedirect.com/science/article/B6T9H-4604280-6/2/7eb545b5a8d192a047b2c6214e288393>

In zebrafish, maternally produced vasa (vas) transcripts become targeted to the cleavage planes of early embryos and subsequently incorporated into the primordial germ cells (PGCs). Zygotic vas transcription occurs from the onset of gastrulation. Here, we report on the characterisation of the zebrafish vas locus. The gene consists of 27 exons, spans about 25 kb, and contains two CpG-rich regions. We have used vas regulatory regions to establish transgenic zebrafish lines expressing enhanced green fluorescent protein (EGFP) in their PGCs. Maternally encoded vas:EGFP transcripts and VAS:EGFP protein segregate with the PGCs during embryogenesis. We find that the maternally deposited vas:EGFP transcripts are stable during embryogenesis at least up to 50 h of development. Vas:EGFP transcripts could not be detected in embryos that inherit the transgene from males, most likely due to the lack of one or more regulatory elements required for early zygotic expression. We show that vas:EGFP transcripts become enriched to the cleavage planes in early embryos, a finding that supported an RNA localisation signal localised within the vas region of these transcripts.

Panzer, Y., M. R. Esteban, et al. (2001). "Meics, a novel zinc-finger protein which relocates from nuclei to the central meiotic spindle during Drosophila spermatogenesis." Mechanisms of Development **106**(1-2): 151.

<http://www.sciencedirect.com/science/article/B6T9H-43J0R4T-J/2/752eb87171bac6f54629ed701a5cada7>

A Drosophila gene encoding a novel zinc-finger protein, Meics, was cloned using a monoclonal antibody. The predicted amino acid sequence contains 12 zinc-finger motifs of the C2H2-type. During spermatogenesis, Meics distributes intranuclearly at pre- and post-meiotic stages whereas it relocates to central-spindle microtubules at both meiotic divisions.

Pesce, M., X. Wang, et al. (1998). "Differential expression of the Oct-4 transcription factor during mouse germ cell differentiation." Mechanisms of Development **71**(1-2): 89.

<http://www.sciencedirect.com/science/article/B6T9H-3S7XFX8-7/2/442d7cc1db1a11fa82adc5c13c3a9d0c>

The POU transcription factor Oct-4 is expressed in early mouse embryogenesis and in pluripotent

embryonal stem (ES) and embryonal carcinoma (EC) stem cell lines. After gastrulation in the embryo, Oct-4 expression is confined to the germline. The present study provides evidence that Oct-4 undergoes downregulation during oogenesis and spermatogenesis, coincident with entry into meiosis. Furthermore, analysis of maturation stages of oocytes showed that Oct-4 is upregulated de novo in the final stages of meiotic prophase I in female germ cells. These data suggest that Oct-4 downregulation in germ cells in both sexes might represent one of the molecular triggers involved in the commitment to meiosis. The upregulation of Oct-4 in oocytes at the completion of the prophase I of meiotic division further suggests a specific involvement of this transcription factor in oocyte growth or the acquisition of meiotic competence.

Pitera, J. E., P. J. Milla, et al. (2001). "Cloning of HOXD1 from unfertilised human oocytes and expression analyses during murine oogenesis and embryogenesis." Mechanisms of Development **109**(2): 377.

<http://www.sciencedirect.com/science/article/B6T9H-442HVW8-7/2/03317bce14226ec767e32a210f8f35bd>

We describe the cloning of HOXD1 in human unfertilised oocytes and detailed expression analyses during mouse oogenesis and embryogenesis. The cDNA of 1991 bp has an open reading frame of 987 bp encoding a protein of 329 amino acids. A comparison of the amino acid sequence with the mouse homologue revealed an overall homology of 85.5% with 99% identity within the homeodomain. Expression was detected in unfertilised human oocytes and 2-, 4-, 8-cell and blastocyst stage embryos. Expression analyses in mature mouse ovaries, early embryos and isolated gut revealed expression in the oocytes of the primary and secondary ovarian follicles, and in embryonal mesodermal derivatives such as dermatomes, urogenital tubercle, tail bud, kidney, ovaries, testes and enteric mesoderm adjacent to the caecum where expression was up-regulated in vitro in response to increasing doses of retinoic acid. Our observations indicate a possible role for HOXD1/Hoxd1 in the ovarian oocytes and the establishment of mesodermal derivatives during embryogenesis.

Ritvos, O., T. Tuuri, et al. (1995). "Activin disrupts epithelial branching morphogenesis in developing glandular organs of the mouse." Mechanisms of Development **50**(2-3): 229.

<http://www.sciencedirect.com/science/article/B6T9H-3YVM6H9-C/2/e25af882159dbec2fc406420442d1f18>

We report that activin profoundly alters epithelial branching morphogenesis of embryonic mouse salivary gland, pancreas and kidney rudiments in culture, indicating that it may play a role as a morphogen during mammalian organogenesis. In developing pancreas and salivary gland rudiments, activin causes severe disruption of normal lobulation patterns of the epithelium whereas follistatin, an activin-binding protein, counteracts the effect of activin. In the kidney, activin delays branching of the ureter bud and reduces the number of secondary branches. TGF- β induces a pattern of aberrant branching in the ureter bud derived epithelium distinct from that seen for activin. Reverse-transcriptase polymerase chain reaction, Northern hybridization and in situ hybridization analyses indicate that these developing tissues express the mRNA transcripts for activin subunits, follistatin or activin receptors. Our results are suggestive of a potential role for the activin-follistatin system as an intrinsic regulator of epithelial branching morphogenesis during mammalian organogenesis.

Rizzoti, K., L. Paquereau, et al. (1998). "A constitutively activated mutant of G[alpha]q down-regulates EP-cadherin expression and decreases adhesion between ectodermal cells at gastrulation." Mechanisms of Development **76**(1-2): 19.

<http://www.sciencedirect.com/science/article/B6T9H-3TVXPY2-2/2/eb15a9ff7e6d023a3ed50957deabe16d>

We have examined the expression and function of the heterotrimeric GTP-binding protein Gq during early *Xenopus* embryogenesis. Abundant XG[alpha]q transcripts were detected in oocytes and early embryos by Northern blot analysis. In situ hybridization revealed that these transcripts are confined to the animal hemisphere of the mature oocyte and to the presumptive ectoderm of cleaving embryos. Microinjection at the two-cell stage of [alpha]q and Q209L[alpha]q, a constitutively activated mutant, causes a disruption in ectodermal cell adhesion at late gastrulation. Dissociation/reaggregation experiments performed on animal cap explants clearly demonstrate that the Q209L[alpha]q-induced phenotype occurs after reaggregation of the explants with a time-course similar to that observed in whole embryos. RT-PCR experiments performed on the explants from Q209L[alpha]q-injected embryos revealed a selective decrease in the amount of EP-cadherin mRNA. Co-injection of EP-cadherin RNA, but also E-cadherin RNA, rescued the disaggregated phenotype. These data emphasize the functional link between Gq protein-coupled signalling pathways and cadherin molecules in the ectodermal layer during the morphogenetic movements of gastrulation.

Sadek, C. M., S. Jalaguier, et al. (2000). "Isolation and characterization of AINT: a novel ARNT interacting protein expressed during murine embryonic development." Mechanisms of Development **97**(1-2): 13.

<http://www.sciencedirect.com/science/article/B6T9H-41WC91G-2/2/cfb86c4d1a056d349d6affabb5b07c4b>

Basic helix-loop-helix-PER-ARNT-SIM (bHLH-PAS) proteins form dimeric transcription factors to mediate diverse biological functions including xenobiotic metabolism, hypoxic response, circadian rhythm and central nervous system midline development. The Ah receptor nuclear translocator protein (ARNT) plays a central role as a common heterodimerization partner. Herein, we describe a novel, embryonically expressed, ARNT interacting protein (AINT) that may be a member of a larger coiled-coil PAS interacting protein family. The AINT C-terminus mediates interaction with the PAS domain of ARNT in yeast and interacts in vitro with ARNT and ARNT2 specifically. AINT localizes to the cytoplasm and overexpression leads to non-nuclear localization of ARNT. A dynamic pattern of AINT mRNA expression during embryogenesis and cerebellum ontogeny supports a role for AINT in development.

Shiraishi, E., H. Imazato, et al. (2004). "Identification of two teleost homologs of the *Drosophila* sex determination factor, transformer-2 in medaka (*Oryzias latipes*)." Mechanisms of Development **121**(7-8): 991.

<http://www.sciencedirect.com/science/article/B6T9H-4CNCT3Y-15/2/01aba50ed0f08aa1fdee8b4d47681b0c>

Transformer-2 (Tra2), an RNA-binding protein, is an important regulator in *Drosophila* sex determination. In vertebrates, however, the role of Tra2 homologues is not known. We identified two teleost homologues of Tra2, which we named Tra2a and Tra2b, in medaka (*Oryzias latipes*). Furthermore, we demonstrated that both Tra2 mRNAs were predominantly expressed in germ

cells of both sexes before the onset of sex differentiation, suggesting that both Tra2 homologues might be involved in the sex differentiation in medaka.

Su, M.-T., T. V. Venkatesh, et al. (1999). "The pioneer gene, *apontic*, is required for morphogenesis and function of the *Drosophila* heart." Mechanisms of Development **80**(2): 125.

<http://www.sciencedirect.com/science/article/B6T9H-3VYXXTM-1/2/de2653189cf412699c6dced32a9e7064>

In an effort to isolate genes required for heart development and to further our understanding of cardiac specification at the molecular level, we screened PlacZ enhancer trap lines for expression in the *Drosophila* heart. One of the lines generated in this screen, designated B2-2-15, was particularly interesting because of its early pattern of expression in cardiac precursor cells, which is dependent on the homeobox gene *tinman*, a key determinant of heart development in *Drosophila*. We isolated and characterized a gene in the vicinity of B2-2-15 that exhibits an identical expression pattern than the reporter gene of the enhancer trap. The product of this gene, *apontic* (*apt*; see also Gellon et al., 1997), does not appear to have any homology with known genes. *apt* mutant embryos show distinct abnormalities in heart morphology as early as mid-embryonic stages when the heart tube assembles, in that segments of heart cells (those of myocardial and pericardial identity) are often missing. Most strikingly, however, *apt* mutant embryos or larvae only develop a much reduced heart rate, perhaps because of defects in the assembly of an intact heart tube and/or because of defects in the function or physiological control of the myocardial cells, which normally mediate heart contractions. These cardiac defects may be the cause of death of these mutants during late embryonic or early larval stages.

Teel, A. L. and H. J. Yost (1996). "Embryonic expression patterns of *Xenopus* syndecans." Mechanisms of Development **59**(2): 115.

<http://www.sciencedirect.com/science/article/B6T9H-3W2TBCW-2/2/427b27f79a11de50f30f8b32786159a2>

Syndecans are a family of heparan sulfate proteoglycans implicated in cell-cell and cell-matrix interactions. To investigate the roles of syndecans in early development, we identified three syndecan family members in *Xenopus laevis*: Xsyn-1, Xsyn-2, and Xsyn-3. Xsyn-1 and Xsyn-2 are maternal mRNAs localized to the animal pole in blastulae, and are expressed in the ectoderm of gastrulae. In neurulae, Xsyn-1 is restricted to non-neural ectoderm and Xsyn-2 is restricted to neural ectoderm. In tailbud embryos, the three syndecans are expressed in adjacent, non-overlapping patterns. Xsyn-2 is expressed in the heart while Xsyn-1 is expressed in the underlying anterior endoderm. Xsyn-3 is expressed in the hindbrain, midbrain, and forebrain, while Xsyn-2 is expressed in the intervening regions. These results suggest that different members of the syndecan family have distinct developmental roles, perhaps acting as barriers to define tissue boundaries.

Therond, P., D. Busson, et al. (1993). "Molecular organisation and expression pattern of the segment polarity gene *fused* of *Drosophila melanogaster*." Mechanisms of Development **44**(1): 65.

<http://www.sciencedirect.com/science/article/B6T9H-491V0TK-BS/2/4ce61c3c52d835e9cff9c24f5c44d846>

The *Drosophila* segment-polarity gene *fused* (*fu*) is required for pattern formation within embryonic segments and imaginal discs. We previously reported that the 5' part of the *fused* gene is homologous to the catalytic domain of serine/threonine kinases. We present here the sequence of the complete transcription unit, which predicts a 805 amino acid long protein. The kinase domain actually corresponds to 268 amino acids in the N-terminal part, and no known function can be attributed to the rest of the putative FUSED protein. Transcripts from the *fused* gene have been characterized: a unique 3.2 kb *fused* transcript is produced in nurse cells, in low abundance, from stage 8 of oogenesis, and persistently through the rest of oogenesis. In embryos, this transcript is evenly distributed in all embryonic cells until the extended germ band stage, after which its amount strongly decreases. Ubiquitous expression is detected later in imaginal wing and leg discs. Possible roles of the FUSED protein in signal transduction pathways required for intercellular communication at different stages of development are discussed.

Wibrand, K. and L. C. Olsen (2002). "Linker histone H1M transcripts mark the developing germ line in zebrafish." Mechanisms of Development **117**(1-2): 249.

<http://www.sciencedirect.com/science/article/B6T9H-460M9MW-2/2/9c0f506d29c7142bb60bd4fca58fc2ae>

Maternally synthesised factors contribute to the establishment of the germ cell lineage in lower vertebrates. In zebrafish, germ-soma segregation appears to be completed by the late blastula stage of development. To search for new germ cell factors in the zebrafish, we have used subtractive cDNA cloning. Here we report that linker histone H1M transcripts mark the germ line from the early gastrulation up to 18 h post-fertilisation.

Metabolic Engineering (2)

Tao, L., R. E. Jackson, et al. (2005). "Directed evolution of copy number of a broad host range plasmid for metabolic engineering." Metabolic Engineering **7**(1): 10.

<http://www.sciencedirect.com/science/article/B6WN3-4F6CRCC-4/2/43a817de209efe98b03e17b2f861ae6e>

Random mutagenesis and directed evolution has been successfully used to improve desired properties of enzymes for biocatalysis and metabolic engineering. Here we employ the method to increase copy number of a pBBR-based broad host range plasmid, which can be used to express desired enzymes in a variety of microbial hosts. Localized random mutagenesis was performed in the replication control region of a pBBR-derived plasmid containing a [beta]-carotene reporter. Mutant plasmids were isolated that showed increased [beta]-carotene production. Real-time PCR analysis confirmed that the copy number of the mutant plasmids increased 3-7 fold. Sequence of the 10 mutant plasmids indicated that each plasmid contained single or multiple mutations in the *rep* gene or the flanking regions. Single amino acid change of serine to leucine at codon 100 of the replication protein and single nucleotide change of C to T at 46 bp upstream of the *rep* gene caused the increase of plasmid copy number. The utility of the mutant plasmids for metabolic engineering were further demonstrated by increased [beta]-carotene production, when an isoprenoid pathway gene (*dxs*) was co-expressed on a compatible plasmid. The mutant plasmids were tested in *Agrobacterium tumefaciens*. Increase of plasmid copy number and [beta]-carotene

production was also observed in the non-Escherichia coli host.

Van Eenennaam, A. L., G. Li, et al. (2004). "Elevation of seed [alpha]-tocopherol levels using plant-based transcription factors targeted to an endogenous locus." *Metabolic Engineering* **6**(2): 101.

<http://www.sciencedirect.com/science/article/B6WN3-4B66812-1/2/d85f7d659795e1b56e6472c256990fbd>

Synthetic zinc finger transcription factors (ZFP-TFs) were designed to upregulate the expression of the endogenous Arabidopsis [gamma]-tocopherol methyltransferase (GMT) gene. This gene encodes the enzyme responsible for the conversion of [gamma]-tocopherol to [alpha]-tocopherol, the tocopherol species with the highest vitamin E activity. Five three-finger zinc finger protein (ZFP) DNA binding domains were constructed and proven to bind tightly to 9 bp DNA sequences located in either the promoter or coding region of the GMT gene. When these ZFPs were fused to a nuclear localization signal and the maize C1 activation domain, four of the five resulting ZFP-TFs were able to upregulate the expression of the GMT gene in leaf protoplast transient assays. Seed-specific expression of these ZFP-TFs in transgenic Arabidopsis produced several lines with a heritable elevation in seed [alpha]-tocopherol. These results demonstrate that engineered ZFP-TFs comprised of plant-derived elements are capable of modulating the expression of endogenous genes in plants.

Metabolism (6)

Hallman, D. M., S. R. Srinivasan, et al. (2004). "The [beta]2-adrenergic receptor Arg16-gly polymorphism and interactions involving [beta]2- and [beta]3-adrenergic receptor polymorphisms are associated with variations in longitudinal serum lipid profiles: The Bogalusa Heart Study." *Metabolism* **53**(9): 1184.

<http://www.sciencedirect.com/science/article/B6WN4-4D4T0WJ-R/2/730400e89fda7a2349546e4dab4e90c1>

We examined the effects of combined genotypes of the [beta]2-adrenergic receptor (AR) Arg16-Gly and [beta]3-AR Trp64-Arg polymorphisms on longitudinal serum total (T-C) and low-density lipoprotein cholesterol (LDL-C) profiles in 1,198 subjects examined multiple times (6,488 observations) from 1973 to 1996 in the Bogalusa Heart Study, at ages from 4.5 to 38 years. Within 5-year age groups, T-C was significantly (P 2-AR Arg16/Arg16 homozygotes than in Gly16 carriers among those 4 to 8 (171.4 +/- 30.0 v 161.5 +/- 27.7 mg/dL), 9 to 13 (167.7 +/- 28.6 v 162.4 +/- 27.4 mg/dL), and 14 to 18 (158.8 +/- 29.6 v 154.7 +/- 27.5 mg/dL) years of age, but not in those 19 to 23, 24 to 28, 29 to 33, or 34 to 38 years of age. The [beta]3-AR polymorphism was not associated with variation in either T-C or LDL-C. In multilevel polynomial growth curve models, the combination of the [beta]2-AR Arg16/Arg16 genotype with either the [beta]3-AR Arg64/Arg64 or Trp64/Arg64 genotypes, denoted AA/AX, was associated with variation in longitudinal T-C (P 2/[beta]3-AR genotype and lipid profiles differed among race/sex groups, being most marked in black females, in whom the AA/AX combination was associated with higher T-C and LDL-C profiles across all ages. In White males, the AA/AX combination was most strongly associated with higher lipids in adults. In black males and white females, lipid profiles differed little between genotype groups. Our findings suggest that the [beta]2-AR Arg16-Gly

genotype influences T-C and LDL-C levels in an age-specific manner, that it may interact with [beta]3-AR Trp64-Arg genotypes to influence longitudinal T-C and LDL-C profiles, and that the effect of combined [beta]2/[beta]3-AR genotypes on T-C and LDL-C profiles may differ among race/sex groups.

Kristensen, K., S. B. Pedersen, et al. (1999). "Regulation of leptin by thyroid hormone in humans: Studies in vivo and in vitro." Metabolism **48**(12): 1603.

<http://www.sciencedirect.com/science/article/B6WN4-4D6XM8X-P/2/71e015d9814feeb4834df33c865f83e8>

The influence of thyroid hormones on human adipose tissue leptin production and leptin gene expression was investigated in vitro and in vivo. Twelve women received 60 [mu]g triiodothyronine (T3) per day for 7 days, which increased total T3 by 195% (1.78 +/- 0.07 to 5.25 +/- 0.39 mU/L, P P P v 8.90 +/- 1.3 [mu]g/L, nonsignificant). Human subcutaneous adipose tissue biopsies from eight healthy women were incubated in vitro as small fragments with T3 in concentrations from 1 to 50 nmol/L. Leptin production was inhibited dose-dependently. After 24 hours of incubation, a T3 concentration of 50 nmol/L reduced basal leptin production by 42% (P P 3 decreased basal leptin mRNA expression by 47% compared with controls (P 3 (> 20 nmol/L) inhibited leptin production and leptin gene expression in vitro, whereas an elevation of T3 corresponding to a moderate thyrotoxic state (T3 5.25 +/- 0.39 nmol/L) was without any impact on serum leptin levels in vivo.

Sbraccia, P., A. Giaccari, et al. (1998). "Expression of the two insulin receptor isoforms is not altered in the skeletal muscle and liver of diabetic rats." Metabolism **47**(2): 129.

<http://www.sciencedirect.com/science/article/B6WN4-4D6XKW1-BG/2/6ecac3d43fc9168afdcbacd4302ae04c>

Alternative splicing of the 36--base pair exon 11 of the human insulin receptor (IR) gene and of the corresponding domain of the rat IR gene results in the synthesis of two IR isoforms with distinct functional characteristics. Altered expression of these IR isoforms has been previously demonstrated in the skeletal muscle of patients with non--insulin-dependent diabetes mellitus (NIDDM); however, this observation was not confirmed by other studies and is still a matter of debate. To assess whether the reported altered isoform expression is due to the secondary metabolic derangement of diabetes, we examined alternative splicing of IR mRNAs (IR36+ and IR36-, corresponding to human Ex11+ and Ex11-) in the skeletal muscle and liver of 6-hour fasting 90% pancreatectomized insulin-resistant diabetic and control Sprague-Dawley rats, using the reverse transcriptase--polymerase chain reaction (PCR) technique. Both diabetic and control rats showed the same pattern of IR mRNA expression: the liver exclusively expressed IR36+ mRNA, whereas only IR36- mRNA was detected in muscle. In conclusion, diabetes mellitus per se does not alter the expression of IR isoforms in the liver and skeletal muscle, and therefore, at least in this animal model of NIDDM, impaired insulin action develops independently from a relative increase in IR36+ mRNA expression in skeletal muscle.

Srinivasan, S. R., S. Li, et al. (2003). "R219K polymorphism of the ABCA1 gene and its modulation of the variations in serum high-density lipoprotein cholesterol and triglycerides related to age and adiposity in white versus black young adults. The bogalusa heart study." Metabolism **52**(7): 930.

<http://www.sciencedirect.com/science/article/B6WN4-490H4VJ-X/2/c8b9f4173d4dcfe1cfd1461f5473b4ce>

Mutations in adenosine triphosphate (ATP)-binding cassette transporter 1 (ABCA1) gene have been established as the molecular defect in Tangier disease and familial hypoalphalipoproteinemia, uncommon genetic disorders characterized by deficient or depressed high-density lipoprotein (HDL) cholesterol and increased triglycerides. However, information regarding the frequency of common variants, including Arg219Lys (R219K) within the coding region of the ABCA1 gene and their effect on these phenotypes in the general population is limited. This study examined the frequency and phenotypic effect of R219K variant in a community-based sample of 887 white and 390 black young adults aged 20 to 38 years. The frequency of the variant allele (K219) was higher in blacks than in whites (0.595 v 0.262, $P = .029$) were found in whites. Carriers (KK+RK), unlike noncarriers (RR) showed a positive relationship between age and HDL cholesterol (regression coefficient $[\beta] = 0.28$, $P = .029$ for carriers v $[\beta] = -0.18$, $P = .112$ for noncarriers). In addition, the variant allele attenuated the adverse positive relationship between BMI and triglycerides ($[\beta] = 0.032$, $P < .001$ for noncarriers). These results indicate that the K219 allele frequency differs markedly between blacks and whites, and that the variant-allele modulates the association between age and HDL cholesterol, as well as body fatness and triglycerides in a beneficial manner only in whites.

Yokoyama, H., H. Tahara, et al. (2005). "The K469E polymorphism of the intercellular adhesion molecule-1 gene is associated with plasma fibrinogen level in type 2 diabetes." *Metabolism* **54**(3): 381.

<http://www.sciencedirect.com/science/article/B6WN4-4FHJ9TP-P/2/1d74028a8ffe955a62d3eb0d8835d4a9>

Intercellular adhesion molecule-1 (ICAM-1) is involved in inflammation and development of atherosclerotic change of vascular endothelium. The aim of the present study is to investigate whether K469E polymorphism of the ICAM-1 gene is associated with various clinical factors including plasma fibrinogen in patients with type 2 diabetes. ICAM-1 gene polymorphism was examined using polymerase chain reaction and restriction enzyme analysis in 360 type 2 diabetic patients. Plasma fibrinogen levels and other clinical variables were measured as well as circulating soluble ICAM-1 (sICAM-1) levels by enzyme-linked immunosorbent assay. The distribution of ICAM-1 genotypes, EE, EK, and KK, was not significantly different between type 2 diabetes and 152 healthy control subjects. Among 3 groups according to ICAM-1 genotypes in type 2 diabetes, no difference was found in adiposity, glycemic control, lipid profile, insulin sensitivity evaluated by homeostasis model assessment, or sICAM-1. Regarding fibrinogen, the patients with E allele showed significantly lower plasma fibrinogen levels in a dose-dependent manner ($P = .033$). Spearman rank correlation analyses revealed that ICAM-1 genotype showed significant correlation with plasma fibrinogen level ($P R^2 = 0.148$, $P < .001$). In conclusion, K469E polymorphism of the ICAM-1 gene had impact on plasma fibrinogen level independently of other clinical factors in 360 type 2 diabetic patients, suggesting that fibrinogen is a candidate which links the ICAM-1 gene polymorphism to atherosclerosis.

Yuan, X., K. Yamada, et al. (1999). "Analysis of trinucleotide-repeat combination polymorphism at the rad gene in patients with type 2 diabetes mellitus." *Metabolism* **48**(2): 173.

<http://www.sciencedirect.com/science/article/B6WN4-4D6XKP9-92/2/8d44da8220b4da43689ae4c75f751676>

A combined (GTT)_n (ATT)_n trinucleotide-repeat polymorphism designated as RAD1 has been

identified at intron 2 of the rad gene on chromosome 16q. An association between the total length of the RAD1 locus and type 2 diabetes has been shown in white American subjects, but not in Finns. We genotyped 115 Japanese patients with type 2 diabetes and 114 nondiabetic control subjects at the RAD1 locus by the direct sequencing method, and found 16 RAD1 alleles composed of various combinations of GTTs and ATTs. Allele 14 consisting of four GTTs and seven ATTs accounted for the majority in both control subjects and diabetic patients, suggesting that RAD1 polymorphism is not a major genetic component for susceptibility to common forms of diabetes in the Japanese. There was no significant association between total repeat length and diabetes. However, the frequency of minor alleles containing five GTTs or three GTTs was significantly higher in diabetic patients versus nondiabetic subjects (4.8% v 0.9%, $P = .012$). Thus, genetic variability at the rad gene in linkage disequilibrium with RAD1 could be associated with a predisposition to type 2 diabetes in the Japanese population.

Adapter-tagged competitive PCR (ATAC-PCR) is an advanced version of competitive quantitative PCR that is characterized by the addition of unique adapters to cDNA derived from each sample RNA. Using multiple adapters, we can accurately measure the relative expression ratios of many samples, with a calibration curve obtained from internal standards included in the same reaction. ATAC-PCR can identify differences in gene expression as small as twofold, even from very small amounts of sample RNA. This technique is suitable for confirming results obtained with cDNA microarrays or differential display, and it can process more than a thousand of genes per day when used in conjunction with a capillary DNA sequencer.

Askjaer, P., V. Galy, et al. (2002). "Ran GTPase Cycle and Importins alpha and beta Are Essential for Spindle Formation and Nuclear Envelope Assembly in Living *Caenorhabditis elegans* Embryos." Mol. Biol. Cell **13**(12): 4355-4370.

<http://www.molbiolcell.org/cgi/content/abstract/13/12/4355>

The small GTPase Ran has been found to play pivotal roles in several aspects of cell function. We have investigated the role of the Ran GTPase cycle in spindle formation and nuclear envelope assembly in dividing *Caenorhabditis elegans* embryos in real time. We found that Ran and its cofactors RanBP2, RanGAP, and RCC1 are all essential for reformation of the nuclear envelope after cell division. Reducing the expression of any of these components of the Ran GTPase cycle by RNAi leads to strong extranuclear clustering of integral nuclear envelope proteins and nucleoporins. Ran, RanBP2, and RanGAP are also required for building a mitotic spindle, whereas astral microtubules are normal in the absence of these proteins. RCC1(RNAi) embryos have similar abnormalities in the initial phase of spindle formation but eventually recover to form a bipolar spindle. Irregular chromatin structures and chromatin bridges due to spindle failure were frequently observed in embryos where the Ran cycle was perturbed. In addition, connection between the centrosomes and the male pronucleus, and thus centrosome positioning, depends upon the Ran cycle components. Finally, we have demonstrated that both IMA-2 and IMB-1, the homologues of vertebrate importin [alpha] and [beta], are essential for both spindle assembly and nuclear formation in early embryos.

Chou, W.-C., V. Prokova, et al. (2003). "Mechanism of a Transcriptional Cross Talk between Transforming Growth Factor-beta -regulated Smad3 and Smad4 Proteins and Orphan Nuclear Receptor Hepatocyte Nuclear Factor-4." Mol. Biol. Cell **14**(3): 1279-1294.

<http://www.molbiolcell.org/cgi/content/abstract/14/3/1279>

We have shown previously that the transforming growth factor-[beta] (TGF[beta])-regulated Smad-Mad (Smad) protein 3 and Smad4 proteins transactivate the apolipoprotein C-III promoter in hepatic cells via a hormone response element that binds the nuclear receptor hepatocyte nuclear factor 4 (HNF-4). In the present study, we show that Smad3 and Smad4 but not Smad2 physically interact with HNF-4 via their Mad homology 1 domains both in vitro and in vivo. The synergistic

transactivation of target promoters by Smads and HNF-4 was shown to depend on the specific promoter context and did not require an intact [beta]-hairpin/DNA binding domain of the Smads. Using glutathione S-transferase interaction assays, we established that two regions of HNF-4, the N-terminal activation function 1 (AF-1) domain (aa 1-24) and the C-terminal F domain (aa 388-455) can mediate physical Smad3/HNF-4 interactions in vitro. In vivo, Smad3 and Smad4 proteins enhanced the transactivation function of various GAL4-HNF-4 fusion proteins via the AF-1 and the adjacent DNA binding domain, whereas a single tyrosine to alanine substitution in AF-1 abolished coactivation by Smads. The findings suggest that the transcriptional cross talk between the TGF[beta]-regulated Smads and HNF-4 is mediated by specific functional domains in the two types of transcription factors. Furthermore, the specificity of this interaction for certain target promoters may play an important role in various hepatocyte functions, which are regulated by TGF[beta] and the Smads.

Eisenkolb, M., C. Zenzmaier, et al. (2002). "A Specific Structural Requirement for Ergosterol in Long-chain Fatty Acid Synthesis Mutants Important for Maintaining Raft Domains in Yeast." Mol. Biol. Cell **13**(12): 4414-4428.

<http://www.molbiolcell.org/cgi/content/abstract/13/12/4414>

Fungal sphingolipids contain ceramide with a very-long-chain fatty acid (C26). To investigate the physiological significance of the C26-substitution on this lipid, we performed a screen for mutants that are synthetically lethal with ELO3. Elo3p is a component of the ER-associated fatty acid elongase and is required for the final elongation cycle to produce C26 from C22/C24 fatty acids. elo3[Delta] mutant cells thus contain C22/C24- instead of the natural C26-substituted ceramide. We now report that under these conditions, an otherwise nonessential, but also fungal-specific, structural modification of the major sterol of yeast, ergosterol, becomes essential, because mutations in ELO3 are synthetically lethal with mutations in ERG6. Erg6p catalyzes the methylation of carbon atom 24 in the aliphatic side chain of sterol. The lethality of an elo3[Delta] erg6[Delta] double mutant is rescued by supplementation with ergosterol but not with cholesterol, indicating a vital structural requirement for the ergosterol-specific methyl group. To characterize this structural requirement in more detail, we generated a strain that is temperature sensitive for the function of Erg6p in an elo3[Delta] mutant background. Examination of raft association of the GPI-anchored Gas1p and plasma membrane ATPase, Pma1p, in the conditional elo3[Delta] erg6ts double mutant, revealed a specific defect of the mutant to maintain raft association of preexisting Pma1p. Interestingly, in an elo3[Delta] mutant at 37{degrees}C, newly synthesized Pma1p failed to enter raft domains early in the biosynthetic pathway, and upon arrival at the plasma membrane was rerouted to the vacuole for degradation. These observations indicate that the C26 fatty acid substitution on lipids is important for establishing raft association of Pma1p and stabilizing the protein at the cell surface. Analysis of raft lipids in the conditional mutant strain revealed a selective enrichment of ergosterol in detergent-resistant membrane domains, indicating that specific structural determinants on both sterols and sphingolipids are required for their association into raft domains.

<http://www.molbiolcell.org/cgi/content/abstract/E04-11-0982v1>

Monitoring Editor: Tim Stearns
The fission yeast Mcs6-Mcs2-Pmh1 complex, homologous to metazoan Cdk7-cyclin H-Mat1, has dual functions in cell division and transcription: as a partially redundant CDK-activating kinase (CAK) that phosphorylates the major cell-cycle CDK, Cdc2, on Thr-167; and as the RNA polymerase (Pol) II carboxyl-terminal domain (CTD) kinase associated

with transcription factor (TF) IIH. We analyzed conditional mutants of *mcs6* and *pmh1*, which activate Cdc2 normally but cannot complete cell division at restrictive temperature and arrest with decreased CTD phosphorylation. Transcriptional profiling by microarray hybridization revealed only modest effects on global gene expression: a one-third reduction in a severe *mcs6* mutant after prolonged incubation at 36°C. In contrast, a small subset of transcripts (~5%) decreased by >2-fold after Mcs6-complex function was compromised. The signature of repressed genes overlapped significantly with those of cell-separation mutants *sep10* and *sep15*. *Sep10*, a component of the Pol II Mediator complex, becomes essential in *mcs6* or *pmh1* mutant backgrounds. Moreover, transcripts dependent on the forkhead transcription factor *Sep1*, which are expressed coordinately during mitosis, were repressed in Mcs6-complex mutants, and Mcs6 also interacts genetically with *Sep1*. Thus the Mcs6 complex, a direct activator of Cdc2, also influences the cell-cycle transcriptional program, possibly through its TFIH-associated kinase function.

Park, E. K., N. Warner, et al. (2004). "Ectopic EphA4 Receptor Induces Posterior Protrusions via FGF Signaling in *Xenopus* Embryos." *Mol. Biol. Cell* **15**(4): 1647-1655.

<http://www.molbiolcell.org/cgi/content/abstract/15/4/1647>

The Eph family of receptor tyrosine kinases regulates numerous biological processes. To examine the biochemical and developmental contributions of specific structural motifs within Eph receptors, wild-type or mutant forms of the EphA4 receptor were ectopically expressed in developing *Xenopus* embryos. Wild-type EphA4 and a mutant lacking both the SAM domain and PDZ binding motif were constitutively tyrosine phosphorylated in vivo and catalytically active in vitro. EphA4 induced loss of cell adhesion, ventro-lateral protrusions, and severely expanded posterior structures in *Xenopus* embryos. Moreover, mutation of a conserved SAM domain tyrosine to phenylalanine (Y928F) enhanced the ability of EphA4 to induce these phenotypes, suggesting that the SAM domain may negatively regulate some aspects of EphA4 activity in *Xenopus*. Analysis of double mutants revealed that the Y928F EphA4 phenotypes were dependent on kinase activity; juxtamembrane sites of tyrosine phosphorylation and SH2 domain-binding were required for cell dissociation, but not for posterior protrusions. The induction of protrusions and expansion of posterior structures is similar to phenotypic effects observed in *Xenopus* embryos expressing activated FGFR1. Furthermore, the budding ectopic protrusions induced by EphA4 express FGF-8, FGFR1, and FGFR4a. In addition, antisense morpholino oligonucleotide-mediated loss of FGF-8 expression in vivo substantially reduced the phenotypic effects in EphA4Y928F expressing embryos, suggesting a connection between Eph and FGF signaling.

Rudge, S. A., D. M. Anderson, et al. (2004). "Vacuole Size Control: Regulation of PtdIns(3,5)P₂ Levels by the Vacuole-associated Vac14-Fig4 Complex, a PtdIns(3,5)P₂-specific Phosphatase." *Mol. Biol. Cell* **15**(1): 24-36.

<http://www.molbiolcell.org/cgi/content/abstract/15/1/24>

In the budding yeast *Saccharomyces cerevisiae*, phosphatidylinositol 3,5-bisphosphate (PtdIns(3,5)P₂) is synthesized by a single phosphatidylinositol 3-phosphate 5-kinase, Fab1. Cells deficient in PtdIns(3,5)P₂ synthesis exhibit a grossly enlarged vacuole morphology, whereas increased levels of PtdIns(3,5)P₂ provokes the formation of multiple small vacuoles, suggesting a specific role for PtdIns(3,5)P₂ in vacuole size control. Genetic studies have indicated that Fab1 kinase is positively regulated by Vac7 and Vac14; deletion of either gene results in ablation of PtdIns(3,5)P₂ synthesis and the formation of a grossly enlarged vacuole. More recently, a suppressor of *vac7*Δ mutants was identified and shown to encode a putative

phosphoinositide phosphatase, Fig4. We demonstrate that Fig4 is a magnesium-activated PtdIns(3,5)P₂-selective phosphoinositide phosphatase in vitro. Analysis of a Fig4-GFP fusion protein revealed that the Fig4 phosphatase is localized to the limiting membrane of the vacuole. Surprisingly, in the absence of Vac14, Fig4-GFP no longer localizes to the vacuole. However, Fig4-GFP remains localized to the grossly enlarged vacuoles of vac7 deletion mutants. Consistent with these observations, we found that Fig4 physically associates with Vac14 in a common membrane-associated complex. Our studies indicate that Vac14 both positively regulates Fab1 kinase activity and directs the localization/activation of the Fig4 PtdIns(3,5)P₂ phosphatase.

Sciorra, V. A., A. Audhya, et al. (2005). "Synthetic Genetic Array Analysis of the PtdIns 4-kinase Pik1p Identifies Components in a Golgi-specific Ypt31/rab-GTPase Signaling Pathway." Mol. Biol. Cell **16**(2): 776-793.

<http://www.molbiolcell.org/cgi/content/abstract/16/2/776>

Phosphorylated derivatives of phosphatidylinositol are essential regulators of both endocytic and exocytic trafficking in eukaryotic cells. In *Saccharomyces cerevisiae*, the phosphatidylinositol 4-kinase, Pik1p generates a distinct pool of PtdIns(4)P that is required for normal Golgi structure and secretory function. Here, we utilize a synthetic genetic array analysis of a conditional pik1 mutant to identify candidate components of the Pik1p/PtdIns(4)P signaling pathway at the Golgi. Our data suggest a mechanistic involvement for Pik1p with a specific subset of Golgi-associated proteins, including the Ypt31p rab-GTPase and the TRAPPII protein complex, to regulate protein trafficking through the secretory pathway. We further demonstrate that TRAPPII specifically functions in a Ypt31p-dependent pathway and identify Gyp2p as the first biologically relevant GTPase activating protein for Ypt31p. We propose that multiple stage-specific signals, which may include Pik1p/PtdIns(4)P, TRAPPII and Gyp2p, impinge upon Ypt31 signaling to regulate Golgi secretory function.

Stang, E., F. D. Blystad, et al. (2004). "Cbl-dependent Ubiquitination Is Required for Progression of EGF Receptors into Clathrin-coated Pits." Mol. Biol. Cell **15**(8): 3591-3604.

<http://www.molbiolcell.org/cgi/content/abstract/15/8/3591>

Ligand binding causes the EGF receptor (EGFR) to become ubiquitinated by Cbl upon association with the adaptor protein Grb2. We have investigated the role of ubiquitin and Grb2 in ligand-induced endocytosis of the EGFR. Incubation of cells with EGF on ice caused translocation of Grb2 and Cbl from the cytosol to the rim of coated pits. Grb2 with point mutations in both SH3 domains inhibited recruitment of the EGFR to clathrin-coated pits, in a Ras-independent manner. On overexpression of the Cbl-binding protein Sprouty, ubiquitination of the EGFR was inhibited, the EGFR was recruited only to the rim of coated pits, and endocytosis of the EGFR was inhibited. Conjugation-defective ubiquitin similarly inhibited recruitment of EGF-EGFR to clathrin-coated pits. Even though this does not prove that cargo must be ubiquitinated, this indicates the importance of interaction of ubiquitinated protein(s) with proteins harboring ubiquitin-interacting domains. We propose that Grb2 mediates transient anchoring of the EGFR to an Eps15-containing molecular complex at the rim of coated pits and that Cbl-induced ubiquitination of the EGFR allows relocation of EGFR from the rim to the center of clathrin-coated pits.

Tatzer, V., G. Zellnig, et al. (2002). "Lipid-dependent Subcellular Relocalization of the Acyl Chain Desaturase in Yeast." Mol. Biol. Cell **13**(12): 4429-4442.

<http://www.molbiolcell.org/cgi/content/abstract/13/12/4429>

The degree of acyl chain desaturation of membrane lipids is a critical determinant of membrane fluidity. Temperature-sensitive mutants of the single essential acyl chain desaturase, Ole1p, of yeast have previously been isolated in screens for mitochondrial inheritance mutants (Stewart, L.C., and Yaffe, M.P. (1991). *J. Cell Biol.* 115, 1249-1257). We now report that the mutant desaturase relocalizes from its uniform ER distribution to a more punctuate localization at the cell periphery upon inactivation of the enzyme. This relocalization takes place within minutes at nonpermissive conditions, a time scale at which mitochondrial morphology and inheritance is not yet affected. Relocalization of the desaturase is fully reversible and does not affect the steady state localization of other ER resident proteins or the kinetic and fidelity of the secretory pathway, indicating a high degree of selectivity for the desaturase. Relocalization of the desaturase is energy independent but is lipid dependent because it is rescued by supplementation with unsaturated fatty acids. Relocalization of the desaturase is also observed in cells treated with inhibitors of the enzyme, indicating that it is independent of temperature-induced alterations of the enzyme. In the absence of desaturase function, lipid synthesis continues, resulting in the generation of lipids with saturated acyl chains. A model is discussed in which the accumulation of saturated lipids in a microdomain around the desaturase could induce the observed segregation and relocalization of the enzyme.

Vedrenne, C., C. Giroud, et al. (2002). "Two Related Subpellicular Cytoskeleton-associated Proteins in *Trypanosoma brucei* Stabilize Microtubules." Mol. Biol. Cell **13**(3): 1058-1070.

<http://www.molbiolcell.org/cgi/content/abstract/13/3/1058>

The subpellicular microtubules of the trypanosome cytoskeleton are cross-linked to each other and the plasma membrane, creating a cage-like structure. We have isolated, from *Trypanosoma brucei*, two related low-molecular-weight cytoskeleton-associated proteins (15- and 17-kDa), called CAP15 and CAP17, which are differentially expressed during the life cycle. Immunolabeling shows a corset-like colocalization of both CAPs and tubulin. Western blot and electron microscope analyses show CAP15 and CAP17 labeling on detergent-extracted cytoskeletons. However, the localization of both proteins is restricted to the anterior, microtubule minus, and less dynamic half of the corset. CAP15 and CAP17 share properties of microtubule-associated proteins when expressed in heterologous cells (Chinese hamster ovary and HeLa), colocalization with their microtubules, induction of microtubule bundle formation, cold resistance, and insensitivity to nocodazole. When overexpressed in *T. brucei*, both CAP15 and CAP17 cover the whole subpellicular corset and induce morphological disorders, cell cycle-based abnormalities, and subsequent asymmetric cytokinesis.

Mol. Biol. Evol.(19)

Beck, N. R., M. C. Double, et al. (2003). "Microsatellite Evolution at Two Hypervariable Loci Revealed by Extensive Avian Pedigrees." Mol. Biol. Evol. **20**(1): 54-61.

<http://mbe.oupjournals.org/cgi/content/abstract/20/1/54>

Genealogies generated through a long-term study of superb fairy-wrens (*Malurus cyaneus*) were used to investigate mutation within two hypervariable microsatellite loci. Of 3,230 meioses examined at the tetranucleotide locus (Mcy{micro}8), 45 mutations were identified, giving a mutation rate of 1.4%. At the dinucleotide locus (Mcy{micro}4) 30 mutations were recorded from 2,750 meioses giving a mutation rate of 1.1%. Mutations at both loci primarily (80%; 60/75) involved the loss or gain of a single repeat unit. Unlike previous studies, there was no significant bias toward additions over deletions. The mutation rate at Mcy{micro}8 increased with allele size, and very long alleles (>70 repeats) mutated at a rate of almost 20%. The length of the mutating allele and allele span, however, were strongly correlated so it was not possible to isolate the causative factor. Allele size did not appear to affect mutation rate at Mcy{micro}4, but the repeat number was considerably lower at this locus. The gender of the mutating parent was significant only at Mcy{micro}8, where mutations occurred more frequently in maternal alleles. However, at both loci we found that alleles inherited from the mother were on average larger than those from the father, and this in part drove the higher mutation rate among maternally inherited alleles at Mcy{micro}8.

Beltran, M., C. D. Jiggins, et al. (2002). "Phylogenetic Discordance at the Species Boundary: Comparative Gene Genealogies Among Rapidly Radiating *Heliconius* Butterflies." Mol. Biol. Evol. **19**(12): 2176-2190.

<http://mbe.oupjournals.org/cgi/content/abstract/19/12/2176>

Recent adaptive radiations provide excellent model systems for understanding speciation, but rapid diversification can cause problems for phylogenetic inference. Here we use gene genealogies to investigate the phylogeny of recent speciation in the heliconiine butterflies. We sequenced three gene regions, intron 3 ({approx}550 bp) of sex-linked triose-phosphate isomerase (Tpi), intron 3 ({approx}450 bp) of autosomal mannose-phosphate isomerase (Mpi), and 1,603 bp of mitochondrial cytochrome oxidase subunits I and II (COI and COII), for 37 individuals from 25 species of *Heliconius* and related genera. The nuclear intron sequences evolved at rates similar to those of mitochondrial coding sequences, but the phylogenetic utility of introns was restricted to closely related geographic populations and species due to high levels of indel variation. For two sister species pairs, *Heliconius erato*-*Heliconius himera* and *Heliconius melpomene*-*Heliconius cydno*, there was highly significant discordance between the three genes. At mtDNA and Tpi, the hypotheses of reciprocal monophyly and paraphyly of at least one species with respect to its sister could not be distinguished. In contrast alleles sampled from the third locus, Mpi, showed polyphyletic relationships between both species pairs. In all cases, recent coalescence of mtDNA lineages within species suggests that polyphyly of nuclear genes is not unexpected. In addition, very similar alleles were shared between *melpomene* and *cydno*, implying recent gene flow. Our finding of discordant genealogies between genes is consistent with models of adaptive speciation with ongoing gene flow and highlights the need for multiple locus comparisons to resolve phylogeny among closely related species.

Bonneton, F., D. Zelus, et al. (2003). "Rapid Divergence of the Ecdysone Receptor in Diptera and Lepidoptera Suggests Coevolution Between ECR and USP-RXR." Mol. Biol. Evol. **20**(4): 541-553.

<http://mbe.oupjournals.org/cgi/content/abstract/20/4/541>

Ecdysteroid hormones are major regulators in reproduction and development of insects, including

larval molts and metamorphosis. The functional ecdysone receptor is a heterodimer of ECR (NR1H1) and USP-RXR (NR2B4), which is the orthologue of vertebrate retinoid X receptors (RXR {alpha}, {beta}, {gamma}). Both proteins belong to the superfamily of nuclear hormone receptors, ligand-dependent transcription factors that share two conserved domains: the DNA-binding domain (DBD) and the ligand-binding domain (LBD). In order to gain further insight into the evolution of metamorphosis and gene regulation by ecdysone in arthropods, we performed a phylogenetic analysis of both partners of the heterodimer ECR/USP-RXR. Overall, 38 USP-RXR and 19 ECR protein sequences, from 33 species, have been used for this analysis. Interestingly, sequence alignments and structural comparisons reveal high divergence rates, for both ECR and USP-RXR, specifically among Diptera and Lepidoptera. The most impressive differences affect the ligand-binding domain of USP-RXR. In addition, ECR sequences show variability in other domains, namely the DNA-binding and the carboxy-terminal F domains. Our data provide the first evidence that ECR and USP-RXR may have coevolved during holometabolous insect diversification, leading to a functional divergence of the ecdysone receptor. These results have general implications on fundamental aspects of insect development, evolution of nuclear receptors, and the design of specific insecticides.

Cohen, S. (2002). "Strong Positive Selection and Habitat-Specific Amino Acid Substitution Patterns in Mhc from an Estuarine Fish Under Intense Pollution Stress." *Mol. Biol. Evol.* **19**(11): 1870-1880.

<http://mbe.oupjournals.org/cgi/content/abstract/19/11/1870>

Population-level studies using the major histocompatibility complex (Mhc) have linked specific alleles with specific diseases, but data requirements are high and the power to detect disease association is low. A novel use of Mhc population surveys involves mapping allelic substitutions onto the inferred structural molecular model to show functional differentiation related to local selective pressures. In the estuarine fish *Fundulus heteroclitus*, populations experiencing strong differences in antigenic challenges show significant differences in amino acid substitution patterns that are reflected as variation in the structural location of changes between populations. Fish from a population genetically adapted to severe chemical pollution also show novel patterns of DNA substitution at a highly variable Mhc class II B locus including strong signals of positive selection at inferred antigen-binding sites and population-specific signatures of amino acid substitution. Heavily parasitized fish from an extreme PCB-contaminated (U.S. Environmental Protection Agency Superfund) site show enhanced population-specific substitutions in the α -helix portion of the inferred antigen-binding region. In contrast, fish from an unpolluted site show a significantly different pattern focused on the first strand of the B-pleated sheet. Whether Mhc population profile differences represent the direct effects of chemical toxicants or indirect parasite-mediated selection, the result is a composite habitat-specific signature of strong selection and evolution affecting the genetic repertoire of the major histocompatibility complex.

Cooper, J. L. and S. Henikoff (2004). "Adaptive Evolution of the Histone Fold Domain in Centromeric Histones." *Mol. Biol. Evol.* **21**(9): 1712-1718.

<http://mbe.oupjournals.org/cgi/content/abstract/21/9/1712>

Centromeric DNA, being highly repetitive, has been refractory to molecular analysis. However, centromeric structural proteins are encoded by single-copy genes, and these can be analyzed by using standard phylogenetic tools. The centromere-specific histone, CenH3, replaces histone H3 in centromeric nucleosomes, and is required for the proper distribution of chromosomes during cell division. Whereas histone H3s are nearly identical between species, CenH3s are divergent, with an N-terminal tail that is highly variable in length and sequence. Both the N-terminal tail and histone fold domain (HFD) are subject to adaptive evolution in *Drosophila*. Similarly, comparisons

between *Arabidopsis thaliana* and *Arabidopsis arenosa* detected adaptive evolution, but only in the N-terminal tail. We have extended our evolutionary analyses of CenH3s to other members of the Brassicaceae, which allowed the detection of positive selection in both the N-terminal tail and in the HFD. We find that adaptively evolving sites in the HFD can potentially interact with DNA, including sites in the loop 1 region of the HFD that are required for centromeric targeting in *Drosophila*. Other adaptively evolving sites in the HFD can be localized on the structure of the nucleosome core particle, revealing an extended surface in addition to loop 1 in which conformational changes might alter histone-DNA contacts or water bridges. The identification of adaptively evolving sites provides a structural basis for the interaction between centromeric DNA and the protein that is thought to underlie the evolution of centromeres and the accumulation of pericentric heterochromatin.

Dvornyk, V., A. Sirvio, et al. (2002). "Low Nucleotide Diversity at the *pal1* Locus in the Widely Distributed *Pinus sylvestris*." *Mol. Biol. Evol.* **19**(2): 179-188.

<http://mbe.oupjournals.org/cgi/content/abstract/19/2/179>

Nucleotide polymorphism in Scots pine (*Pinus sylvestris*) was studied in the gene encoding phenylalanine ammonia-lyase (Pal, EC 4.3.1.5). Scots pine, like many other pine species, has a large current population size. The observed levels of inbreeding depression suggest that Scots pine may have a high mutation rate to deleterious alleles. Many Scots pine markers such as isozymes, RFLPs, and microsatellites are highly variable. These observations suggest that the levels of nucleotide variation should be higher than those in other plant species. A 2,045-bp fragment of the *pal1* locus was sequenced from five megagametophytes each from a different individual from each of four populations, from northern and southern Finland, central Russia, and northern Spain. There were 12 segregating sites in the locus. The synonymous site overall nucleotide diversity was only 0.0049. In order to compare *pal1* with other pine genes, sequence was obtained from two alleles of 11 other loci (total length 4,606 bp). For these, the synonymous nucleotide diversity was 0.0056. These estimates are lower than those from other plants. This is most likely because of a low mutation rate, as estimated from between-pine species synonymous site divergence. In other respects, Scots pine has the characteristics of a species with a large effective population. There was no linkage disequilibrium even between closely linked sites. This resulted in high haplotype diversity (14 different haplotypes among 20 sequences). This could also give rise to high per locus diversity at the protein level. Divergence between populations in the main range was low, whereas an isolated Spanish population had slightly lower diversity and higher divergence than the remaining populations.

Fischer, A., V. Wiebe, et al. (2004). "Evidence for a Complex Demographic History of Chimpanzees." *Mol. Biol. Evol.* **21**(5): 799-808.

<http://mbe.oupjournals.org/cgi/content/abstract/21/5/799>

To characterize patterns of genomic variation in central chimpanzees (*Pan troglodytes troglodytes*) and gain insight into their evolution, we sequenced nine unlinked, intergenic regions, representing a total of 19,000 base pairs, in 14 individuals. When these DNA sequences are compared with homologous sequences previously collected in humans and in western chimpanzees (*Pan troglodytes verus*), nucleotide diversity is higher in central chimpanzees than in western chimpanzees or in humans. Consistent with a larger effective population size of central chimpanzees, levels of linkage disequilibrium are lower than in humans. Patterns of linkage disequilibrium further suggest that homologous gene conversion may be an important contributor to genetic exchange at short distances, in agreement with a previous study of the same DNA sequences in humans. In central chimpanzees, but not in western chimpanzees, the allele

frequency spectrum is significantly skewed towards rare alleles, pointing to population size changes or fine-scale population structure. Strikingly, the extent of genetic differentiation between western and central chimpanzees is much stronger than what is seen between human populations. This suggests that careful attention should be paid to geographic sampling in studies of chimpanzee genetic variation.

Gorinsek, B., F. Gubensek, et al. (2004). "Evolutionary Genomics of Chromoviruses in Eukaryotes." Mol. Biol. Evol. **21**(5): 781-798.

<http://mbe.oupjournals.org/cgi/content/abstract/21/5/781>

The diversity, origin, and evolution of chromoviruses in Eukaryota were examined using the massive amount of genome sequence data for different eukaryotic lineages. A surprisingly large number of novel full-length chromoviral elements were found, greatly exceeding the number of the known chromoviruses. These new elements are mostly structurally intact and highly conserved. Chromoviruses in the key Amniota lineage, the reptiles, have been analyzed by PCR to explain their evolutionary dynamics in amniotes. Phylogenetic analyses provide evidence for a novel centromere-specific chromoviral clade that is widespread and highly conserved in all seed plants. Chromoviral diversity in plants, fungi, and vertebrates, as shown by phylogenetic analyses, was found to be much greater than previously expected. The age of plant chromoviruses has been significantly extended by finding their representatives in the most basal plant lineages, the green and the red algae. The evolutionary origin of chromoviruses has been found to be no earlier than in Cercozoa. The evolutionary history and dynamics of chromoviruses can be explained simply by strict vertical transmission in plants, followed by more complex evolution in fungi and in Metazoa. The currently available data clearly show that chromoviruses indeed represent the oldest and the most widespread clade of Metaviridae.

Hellborg, L. and H. Ellegren (2004). "Low Levels of Nucleotide Diversity in Mammalian Y Chromosomes." Mol. Biol. Evol. **21**(1): 158-163.

<http://mbe.oupjournals.org/cgi/content/abstract/21/1/158>

Sex chromosomes provide a useful context for the study of the relative importance of evolutionary forces affecting genetic diversity. The human Y chromosome shows levels of nucleotide diversity 20% that of autosomes, which is significantly less than expected when differences in effective population size and sex-specific mutation rates are taken into account. To study the generality of low levels of Y chromosome variability in mammalian genomes, we investigated nucleotide diversity in intron sequences of X (1.1-3.0 kb) and Y (0.7-3.5 kb) chromosome genes of five mammals: lynx, wolf, reindeer, cattle, and field vole. For all species, nucleotide diversity was found to be lower on Y than on X, with no segregating site observed in Y-linked sequences of lynx, reindeer, and cattle. For X chromosome sequences, nucleotide diversity was in the range of 1.6×10^{-4} (lynx) to 8.0×10^{-4} (field vole). When differences in effective population size and the extent of the male mutation bias were taken into account, all five species showed evidence of reduced levels of Y chromosome variability. Reduced levels of Y chromosome variability have also been observed in *Drosophila* and in plants, as well as in the female-specific W chromosome of birds. Among the different factors proposed to explain low levels of genetic variability in the sex-limited chromosome (Y/W), we note that selection is the only factor that is broadly applicable irrespective of mode of reproduction and whether there is male or female heterogamety.

Hofreiter, M., C. Capelli, et al. (2002). "Ancient DNA Analyses Reveal High Mitochondrial DNA Sequence Diversity and Parallel Morphological Evolution of Late Pleistocene Cave Bears." Mol. Biol. Evol. **19**(8): 1244-1250.

<http://mbe.oupjournals.org/cgi/content/abstract/19/8/1244>

Cave bears (*Ursus spelaeus*) existed in Europe and western Asia until the end of the last glaciation some 10,000 years ago. To investigate the genetic diversity, population history, and relationship among different cave bear populations, we have determined mitochondrial DNA sequences from 12 cave bears that range in age from about 26,500 to at least 49,000 years and originate from nine caves. The samples include one individual from the type specimen population, as well as two small-sized high-Alpine bears. The results show that about 49,000 years ago, the mtDNA diversity among cave bears was about 1.8-fold lower than the current species-wide diversity of brown bears (*Ursus arctos*). However, the current brown bear mtDNA gene pool consists of three clades, and cave bear mtDNA diversity is similar to the diversity observed within each of these clades. The results also show that geographically separated populations of the high-Alpine cave bear form were polyphyletic with respect to their mtDNA. This suggests that small size may have been an ancestral trait in cave bears and that large size evolved at least twice independently.

Joshi, M. B., P. K. Rout, et al. (2004). "Phylogeography and Origin of Indian Domestic Goats." Mol. Biol. Evol. **21**(3): 454-462.

<http://mbe.oupjournals.org/cgi/content/abstract/21/3/454>

The Indian subcontinent contains 20 well-characterized goat breeds, which vary in their genetic potential for the production of milk, meat, and fibre; disease resistance; heat tolerance; and fecundity. Indian goats make up 20% of the world's goat population, but there has been no extensive study of these economically important animals. Therefore, we have undertaken the present investigation of 363 goats belonging to 10 different breeds from different geographic regions of India using mtDNA sequence data from the HVRI region. We find evidence for population structure and novel lineages in Indian goats and cannot reconcile the genetic diversity found within the major lineage with domestication starting 10,000 years ago from a single mtDNA ancestor. Thus, we propose a more complex origin for domestic goats.

Kitano, T., Y.-H. Liu, et al. (2004). "Human-Specific Amino Acid Changes Found in 103 Protein-Coding Genes." Mol. Biol. Evol. **21**(5): 936-944.

<http://mbe.oupjournals.org/cgi/content/abstract/21/5/936>

We humans have many characteristics that are different from those of the great apes. These human-specific characters must have arisen through mutations accumulated in the genome of our direct ancestor after the divergence of the last common ancestor with chimpanzee. Gene trees of human and great apes are necessary for extracting these human-specific genetic changes. We conducted a systematic analysis of 103 protein-coding genes for human, chimpanzee, gorilla, and orangutan. Nucleotide sequences for 18 genes were newly determined for this study, and those for the remaining genes were retrieved from the DDBJ/EMBL/GenBank database. The total number of amino acid changes in the human lineage was 147 for 26,199 codons (0.56%). The total number of amino acid changes in the human genome was, thus, estimated to be about 80,000. We applied the acceleration index test and Fisher's synonymous/nonsynonymous exact test for each gene tree to detect any human-specific

enhancement of amino acid changes compared with ape branches. Six and two genes were shown to have significantly higher nonsynonymous changes at the human lineage from the acceleration index and exact tests, respectively. We also compared the distribution of the differences of the nonsynonymous substitutions on the human lineage and those on the great ape lineage. Two genes were more conserved in the ape lineage, whereas one gene was more conserved in the human lineage. These results suggest that a small proportion of protein-coding genes started to evolve differently in the human lineage after it diverged from the ape lineage.

Kitano, T., C. Schwarz, et al. (2003). "Gene Diversity Patterns at 10 X-Chromosomal Loci in Humans and Chimpanzees." Mol. Biol. Evol. **20**(8): 1281-1289.

<http://mbe.oupjournals.org/cgi/content/abstract/20/8/1281>

We have investigated the pattern and extent of nucleotide diversity in 10 X-chromosomal genes where mutations are known to cause mental retardation in humans. For each gene, we sequenced the entire coding region from cDNA in humans, chimpanzees, and orangutans, as well as about 3 kb of genomic DNA in 20 humans sampled worldwide and in 10 chimpanzees representing two "subspecies." Overall nucleotide diversity in these genes is about twofold lower in humans than in chimpanzees, and nucleotide diversity within and between species is low, suggesting that a high level of functional constraint acts on these genes. Strikingly, we find that a summary of the allele frequency spectrum is significantly correlated in humans and chimpanzees, perhaps reflecting very similar levels of constraint at these genes in the two species. A possible exception is FMR2, which shows a higher number of nonsynonymous than synonymous substitutions on the human lineage, suggesting the action of positive selection.

McCartney, M. A. and H. A. Lessios (2004). "Adaptive Evolution of Sperm Bindin Tracks Egg Incompatibility in Neotropical Sea Urchins of the Genus *Echinometra*." Mol. Biol. Evol. **21**(4): 732-745.

<http://mbe.oupjournals.org/cgi/content/abstract/21/4/732>

Bindin is a gamete recognition protein known to control species-specific sperm-egg adhesion and membrane fusion in sea urchins. Previous analyses have shown that diversifying selection on bindin amino acid sequence is found when gametically incompatible species are compared, but not when species are compatible. The present study analyzes bindin polymorphism and divergence in the three closely related species of *Echinometra* in Central America: *E. lucunter* and *E. viridis* from the Caribbean, and *E. vanbrunti* from the eastern Pacific. The eggs of *E. lucunter* have evolved a strong block to fertilization by sperm of its neotropical congeners, whereas those of the other two species have not. As in the Indo-West Pacific (IWP) *Echinometra*, the neotropical species show high intraspecific bindin polymorphism in the same gene regions as in the IWP species. Maximum likelihood analysis shows that many of the polymorphic codon sites are under mild positive selection. Of the fixed amino acid replacements, most have accumulated along the bindin lineage of *E. lucunter*. We analyzed the data with maximum likelihood models of variation in positive selection across lineages and codon sites, and with models that consider sites and lineages simultaneously. Our results show that positive selection is concentrated along the *E. lucunter* bindin lineage, and that codon sites with amino acid replacements fixed in this species show by far the highest signal of positive selection. Lineage-specific positive selection paralleling egg incompatibility provides support that adaptive evolution of sperm proteins acts to maintain recognition of bindin by changing egg receptors. Because both egg incompatibility and bindin divergence are greater between allopatric species than between sympatric species, the hypothesis of selection against hybridization (reinforcement) cannot explain why adaptive evolution has been confined to a single lineage in the American *Echinometra*. Instead, processes

acting to varying degrees within species (e.g., sperm competition, sexual selection, and sexual conflict) are more promising explanations for lineage-specific positive selection on *bindin*.

Moum, T., U. Arnason, et al. (2002). "Mitochondrial DNA Sequence Evolution and Phylogeny of the Atlantic Alcidae, Including the Extinct Great Auk (*Pinguinus impennis*)."
Mol. Biol. Evol. **19**(9): 1434-1439.

<http://mbe.oupjournals.org/cgi/content/abstract/19/9/1434>

The Atlantic auk assemblage includes four extant species, razorbill (*Alca torda*), dovekie (*Alle alle*), common murre (*Uria aalge*), and thick-billed murre (*U. lomvia*), and one recently extinct species, the flightless great auk (*Pinguinus impennis*). To determine the phylogenetic relationships among the species, a contiguous 4.2-kb region of the mitochondrial genome from the extant species was amplified using PCR. This region included one ribosomal RNA gene, four transfer RNA genes, two protein-coding genes, the control region, and intergenic spacers. Sets of PCR primers for amplifying the same region from great auk were designed from sequences of the extant species. The authenticity of the great auk sequence was ascertained by alternative amplifications, cloning, and separate analyses in an independent laboratory. Phylogenetic analyses of the entire assemblage, made possible by the great auk sequence, fully resolved the phylogenetic relationships and split it into two primary lineages, *Uria* versus *Alle*, *Alca*, and *Pinguinus*. A sister group relationship was identified between *Alca* and *Pinguinus* to the exclusion of *Alle*. Phylogenetically, the flightless great auk originated late relative to other divergences within the assemblage. This suggests that three highly divergent species in terms of adaptive specializations, *Alca*, *Alle*, and *Pinguinus*, evolved from a single lineage in the Atlantic Ocean, in a process similar to the initial adaptive radiation of alcids in the Pacific Ocean.

Reiss, D., H. Quesneville, et al. (2003). "Hoppel, a P-like Element Without Introns: a P-Element Ancestral Structure or a Retrotranscription Derivative?"
Mol. Biol. Evol. **20**(6): 869-879.

<http://mbe.oupjournals.org/cgi/content/abstract/20/6/869>

An *in silico* search for P-transposable-element-related sequences in the *Drosophila melanogaster* genome allowed us to detect sequences that are similar to P-element transposases. These sequences are located in the central region of 3.4-kb Hoppel elements, a class II transposon. Polymerase chain reaction (PCR) analysis of the insertional polymorphism revealed that these elements are mobile. The 3.4-kb elements are the longest copies of this family ever found. They contain an open reading frame that is long enough to encode a transposase, suggesting that the 3.4-kb elements are the full-length copies of the Hoppel family. Multiple alignments of several P-element transposases from different species and the Hoppel-element-encoded peptide showed that all of the P-element introns and the 5' region of the transposase are absent from the Hoppel sequence. Sequence analysis combined with reverse transcriptase PCR analysis showed that the 3.4-kb Hoppel elements are intronless. P and Hoppel not only share similar amino acid sequences but also have terminal inverted repeats of the same length (31 bp), and their excision footprints present a similar structure, which suggests that their transposases are functionally very similar. Thus, we propose that the Hoppel element family be included in the P-element superfamily. Two evolutionary scenarios are discussed considering the presence /absence of introns within the P-element superfamily.

Staats, M., P. van Baarlen, et al. (2005). "Molecular Phylogeny of the Plant Pathogenic Genus *Botrytis*

and the Evolution of Host Specificity." *Mol. Biol. Evol.* **22**(2): 333-346.

<http://mbe.oupjournals.org/cgi/content/abstract/22/2/333>

The cosmopolitan genus *Botrytis* contains 22 recognized species and one hybrid. The current classification is largely based on morphological characters and, to a minor extent, on physiology and host range. In this study, a classification of the genus was constructed based on DNA sequence data of three nuclear protein-coding genes (RPB2, G3PDH, and HSP60) and compared with the traditional classification. Sexual reproduction and the host range, important fitness traits, were traced in the tree and used for the identification of major evolutionary events during speciation. The phylogenetic analysis corroborated the classical species delineation. In addition, the hybrid status of *B. allii* (*B. byssoidea* x *B. aclada*) was confirmed. Both individual gene trees and combined trees show that the genus *Botrytis* can be divided into two clades, radiating after the separation of *Botrytis* from other Sclerotiniaceae genera. Clade 1 contains four species that all colonize exclusively eudicot hosts, whereas clade 2 contains 18 species that are pathogenic on either eudicot (3) or monocot (15) hosts. A comparison of *Botrytis* and angiosperm phylogenies shows that cospeciation of pathogens and their hosts have not occurred during their respective evolution. Rather, we propose that host shifts have occurred during *Botrytis* speciation, possibly by the acquisition of novel pathogenicity factors. Loss of sexual reproduction has occurred at least three times and is supposed to be a consequence of negative selection.

Taylor, S. D., K. D. de la Cruz, et al. (2005). "Characterization of the Long-Wavelength Opsin from Mecoptera and Siphonaptera: Does a Flea See?" *Mol. Biol. Evol.* **22**(5): 1165-1174.

<http://mbe.oupjournals.org/cgi/content/abstract/22/5/1165>

Mecoptera and Siphonaptera represent two insect orders that have largely been overlooked in the study of insect vision. Recent phylogenetic evidence demonstrates that Mecoptera (scorpionflies) is paraphyletic, with the order Siphonaptera (fleas) nesting as sister to the family Boreidae (snow fleas), showing an evolutionary trend towards reduction in gross eye morphology within fleas. We provide the first molecular characterization of long-wavelength opsins from these three lineages (opsin gene from fleas [FL-Opsin], the Boreidae [B-Opsin], and a mecopteran family [M-Opsin]) and assess the effects of loss of visual acuity on the structure and function of the opsin gene. Phylogenetic analysis implies a physiological sensitivity in the red-green spectrum for these opsins. Analysis of intron splice sites reveals a high degree of similarity between FL-Opsin and B-Opsin as well as conserved splice sites across insect blue-green and long-wavelength opsins. Calculated rates of evolution and tests for destabilizing selection indicate that FL-Opsin, B-Opsin, and M-Opsin are evolving at similar rates with no radical selective pressures, implying conservative evolution and functional constraint across all three lineages.

Zhou, G., Y. Zhai, et al. (2004). "Haplotype Structure and Evidence for Positive Selection at the Human IL13 Locus." *Mol. Biol. Evol.* **21**(1): 29-36.

<http://mbe.oupjournals.org/cgi/content/abstract/21/1/29>

Interleukin-13 (IL13) is believed to play an important role in the pathogenesis of atopy and allergic asthma. To better understand genetic variation at the IL13 locus, we resequenced a 5.1-kb genomic region spanning the entire locus and identified 26 single-nucleotide polymorphisms (SNPs) in 74 individuals from three major populations--Chinese, Caucasian, and African. Our survey suggests exceptionally high and significant geographic structure at the IL13 locus between African and outside Africa populations. This unusual pattern suggests that positive selection that

acts in some local populations may have played a role on the IL13 locus. In support of this suggestion, we found a significant excess of high frequency-derived SNPs in the Chinese population and Caucasian population, respectively, as expected after a recent episode of positive selection. Further, the unusual haplotype structure indicates that different scenarios of the action of positive selection on the IL13 locus in different populations may exist. In the Caucasian population, the skewed haplotype distribution dominated by one common haplotype supports the hypothesis of simple directional selection. Whereas, in the Chinese population, the two-round hitchhiking hypothesis may explain the skewed haplotype structure with three dominant ones. These findings may provide insight into the likely relative roles of selection and population history in establishing present-day variation at the IL13 locus, and, motivate further studies of this locus as an important candidate in common diseases association studies.

Mol. Cancer Res. (2)

Jia, L., J. Kim, et al. (2003). "Androgen Receptor Activity at the Prostate Specific Antigen Locus: Steroidal and Non-Steroidal Mechanisms." Mol. Cancer Res. **1**(5): 385-392.

<http://mcr.aacrjournals.org/cgi/content/abstract/1/5/385>

Ligand-activated androgen receptors (ARs) occupy target genes and recruit histone modifiers that influence transcriptional competency. In LNCaP prostate cancer cells, the natural ligand 5 α -dihydrotestosterone (DHT) activates transiently transfected AR-responsive promoter constructs; concurrent treatment with the protein kinase A activator forskolin enhanced AR stimulation induced by DHT. Additional treatment with the cytokine IL-6, purportedly an AR activator, markedly inhibited receptor activity. To assess AR activity on natural chromatin-integrated promoters/enhancers, we determined AR occupancy of the endogenous prostate specific antigen (PSA) promoter/enhancer as well as PSA expression in LNCaP cells treated with DHT; AR occupancy of the PSA enhancer was rapid (within 1 h of stimulation), robust (10-fold over background), and sustained (8-16 h). In contrast, AR occupancy of the PSA promoter was only increased by 2-fold. Histone H3 acetylation at both the enhancer and promoter was evident 1-2 h after DHT treatment. Detectable pre- and mature PSA mRNA levels appeared after 1 and 6 h treatment, respectively. Substantial qualitative and quantitative differences in PSA expression and AR occupancy of the PSA enhancer were observed when DHT-induced and ligand-independent activations of the AR were compared; forskolin stimulated PSA mRNA and protein expression, whereas IL-6 inhibited both DHT- and forskolin-stimulated expression. IL-6 did not diminish DHT-dependent AR occupancy of the PSA enhancer but inhibited CBP/p300 recruitment, histone H3 acetylation, and cell proliferation. These findings provide a contextual framework for interpreting the contribution of non-steroidal activation of the AR to signaling in vivo, and have implications for prostate cancer cell growth.

Peng, S.-B., V. Peek, et al. (2005). "Akt Activation, but not Extracellular Signal-Regulated Kinase Activation, Is Required for SDF-1 α /CXCR4-Mediated Migration of Epitheloid Carcinoma Cells." Mol. Cancer Res. **3**(4): 227-236.

<http://mcr.aacrjournals.org/cgi/content/abstract/3/4/227>

Emerging evidence shows that the stromal cell-derived factor 1 (SDF-1)/CXCR4 interaction

regulates multiple cell signaling pathways and a variety of cellular functions such as cell migration, proliferation, and survival. There is little information linking the cellular functions and individual signaling pathways mediated by SDF-1 and CXCR4 in human cancer cells. In this study, we have shown that human epitheloid carcinoma HeLa cells express functional CXCR4 by reverse transcription-PCR, immunofluorescent staining, and ^{125}I -SDF-1 $\{\alpha\}$ ligand binding analyses. The treatment of HeLa cells with recombinant SDF-1 $\{\alpha\}$ results in time-dependent Akt and extracellular signal-regulated kinase 1/2 (ERK1/2) activations. The SDF-1 $\{\alpha\}$ -induced Akt and ERK1/2 activations are CXCR4 dependent as confirmed by their total inhibition by T134, a CXCR4-specific peptide antagonist. Cell signaling analysis with pathway-specific inhibitors reveals that SDF-1 $\{\alpha\}$ -induced Akt activation is not required for ERK1/2 activation and vice versa, indicating that activations of Akt and ERK1/2 occur independently. Functional analysis shows that SDF-1 $\{\alpha\}$ induces a CXCR4-dependent migration of HeLa cells. The migration can be totally blocked by phosphoinositide 3-kinase inhibitors, wortmannin or LY294002, whereas mitogen-activated protein/ERK kinase inhibitors, PD98059 and U0126, have no significant effect on SDF-1 $\{\alpha\}$ -induced migration, suggesting that Akt activation, but not ERK1/2 activation, is required for SDF-1 $\{\alpha\}$ -induced migration of epitheloid carcinoma cells.

Mol. Cancer Ther. (5)

Di Nicolantonio, F., L. A. Knight, et al. (2004). "The ex vivo characterization of XR5944 (MLN944) against a panel of human clinical tumor samples." *Mol. Cancer Ther.* **3**(12): 1631-1637.

<http://mct.aacrjournals.org/cgi/content/abstract/3/12/1631>

XR5944 (MLN944) is a novel DNA targeting agent with potent antitumor activity, both in vitro and in vivo, against several murine and human tumor models. We have used an ATP-tumor chemosensitivity assay to assess the ex vivo sensitivity of a variety of solid tumors ($n = 90$) and a CCRF-CEM leukemia cell line selected with XR5944. Differences in gene expression between the parental CCRF-CEM and the resistant subline were investigated by quantitative reverse transcription-PCR. Immunohistochemistry for topoisomerases I and II $\{\alpha\}$ and multidrug resistance (MDR1) protein was done on those tumors for which tissue was available ($n = 32$). The CCRF-CEM XR5944 line showed increased mRNA levels of MDR1, major vault protein, and MDR-associated protein 1 compared with the parental line, whereas the expression of topoisomerases I, II $\{\alpha\}$, and II $\{\beta\}$ was essentially unchanged, suggesting that XR5944 is susceptible to MDR mechanisms. The median IC₉₀ and IC₅₀ values for XR5944 in tumor-derived cells were 68 and 26 nmol/L, respectively, 6-fold greater than in resistant cell lines. XR5944 was 40- to 300-fold more potent than the other cytotoxics tested, such as doxorubicin, topotecan, and paclitaxel. Breast and gynecologic malignancies were most sensitive to XR5944, whereas gastrointestinal tumors showed greater resistance. A positive correlation ($r = 0.68$; $P < 0.0001$) was found between the IC₅₀ values of XR5944 and P-glycoprotein/MDR1 staining but not with either topoisomerase I or II $\{\alpha\}$ immunohistochemistry index. These data support the rapid introduction of XR5944 to clinical trials and suggest that it may be effective against a broad spectrum of tumor types, especially ovarian and breast cancer.

Ikeda, N., H. Uemura, et al. (2003). "Combination Treatment with 1 $\{\alpha\}$,25-Dihydroxyvitamin D₃ and 9-cis-Retinoic Acid Directly Inhibits Human Telomerase Reverse Transcriptase Transcription in Prostate Cancer Cells." *Mol. Cancer Ther.* **2**(8): 739-746.

<http://mct.aacrjournals.org/cgi/content/abstract/2/8/739>

The vitamin D3 receptor, which is the nuclear receptor for 1 α ,25-dihydroxyvitamin D3 (VD3), forms a heterodimer with the retinoid X receptor (RXR), which is the nuclear receptor for 9-cis-retinoic acid (9-cis-RA). The heterodimer binds to a specific response element consisting of two directly repeated pairs of motifs, AGGTGA, spaced by three nucleotides [direct repeat (DR) 3] and modulates the expression of VD3-responsive genes. Telomerase activity, which is seen in most immortal cells and germ cells, is a complex of enzymes that maintain the length of telomeres. One of the major components of human telomerase, human telomerase reverse transcriptase (hTERT), is the catalytic subunit, and the expression of hTERT might correlate most strongly with telomerase activity. We found that the sequence of 5'-AGTTCATGGAGTTCA-3' (DR3') is similar to that of DR3 in the promoter region of hTERT. Our results showed that the combination of VD3 and 9-cis-RA inhibited telomerase activity through direct interaction of the heterodimer of vitamin D3 receptor and RXR with the DR3' sequence in the hTERT promoter as well as the combination of VD3 and selective RXR ligand did. Also, in vivo data showed that the growth of xenografts in nude mice was inhibited by VD3 and 9-cis-RA. The results of the present study provide evidence on the molecular mechanism of the inhibition of cell growth by these agents, and they could be novel therapeutic agents for prostate cancer.

Johnson, P. H., R. P. Walker, et al. (2002). "Multiplex Gene Expression Analysis for High-Throughput Drug Discovery: Screening and Analysis of Compounds Affecting Genes Overexpressed in Cancer Cells." Mol. Cancer Ther. **1**(14): 1293-1304.

<http://mct.aacrjournals.org/cgi/content/abstract/1/14/1293>

Drug discovery strategies are needed that can rapidly exploit multiple therapeutic targets associated with the complex gene expression changes that characterize a polygenic disease such as cancer. We report a new cell-based high-throughput technology for screening chemical libraries against several potential cancer target genes in parallel. Multiplex gene expression (MGE) analysis provides direct and quantitative measurement of multiple endogenous mRNAs using a multiplexed detection system coupled to reverse transcription-PCR. A multiplex assay for six genes overexpressed in cancer cells was used to screen 9000 chemicals and known drugs in the human prostate cancer cell line PC-3. Active compounds that modulated gene expression levels were identified, and IC50 values were determined for compounds that bind DNA, cell surface receptors, and components of intracellular signaling pathways. A class of steroids related to the cardiac glycosides was identified that potently inhibited the plasma membrane Na⁺K⁺-ATPase resulting in the inhibition of four of the prostate target genes including transcription factors Hoxb-13, hPSE/PDEF, hepatocyte nuclear factor-3 α , and the inhibitor of apoptosis, survivin. Representative compounds selectively induced apoptosis in PC-3 cells compared with the nonmetastatic cell line BPH-1. The multiplex assay distinguished potencies among structural variants, enabling structure-activity analysis suitable for chemical optimization studies. A second multiplex assay for five toxicological markers, Hsp70, Gadd153, Gadd45, O6-methylguanine-DNA methyltransferase, and cyclophilin, detected compounds that caused DNA damage and cellular stress and was a more sensitive and specific indicator of potential toxicity than measurement of cell viability. MGE analysis facilitates rapid drug screening and compound optimization, the simultaneous measurement of toxicological end points, and gene function analysis.

Sale, S., R. Sung, et al. (2002). "Conservation of the Class I β -Tubulin Gene in Human Populations and Lack of Mutations in Lung Cancers and Paclitaxel-resistant Ovarian Cancers." Mol. Cancer Ther. **1**(3): 215-225.

<http://mct.aacrjournals.org/cgi/content/abstract/1/3/215>

The goal of this study was to determine the prevalence of sequence variants in the class I β -tubulin (clone m40) gene and their occurrence in human tumors and cancer cell lines. DNA was isolated from 93 control individuals representing a wide variety of ethnicities, 49 paclitaxel-naïve specimens (16 ovarian cancers, 17 non-small cell lung cancers, and 16 ovarian cancer cell lines), and 30 paclitaxel-resistant specimens (9 ovarian cancers, 9 ovarian cancer cell lines, and 12 ovarian cancer xenografts in nude mice). Denaturing high-performance liquid chromatography and direct sequence analysis detected two silent polymorphisms in exon 4, Leu217Leu (CTG/CTA) and Gly400Gly (GGC/GGT), with minor allele frequencies of 17 and 0.5%, respectively. Five nucleotide substitutions and one single-base deletion were detected in introns 1, 2, and 3 and in the 3' untranslated region. Analysis of 49 paclitaxel-naïve and 30 paclitaxel-resistant specimens revealed no additional polymorphisms in the coding region. In addition, no amino acid replacements were found in chimpanzee, gorilla, and orangutan in comparison to human. Our data demonstrate a very high degree of sequence conservation in class I β -tubulin, suggesting that all residues are important in tubulin structure and function. Individual variation in response to treatment with paclitaxel is not likely to be caused by genetic variations in the β -tubulin drug target. Moreover, acquired mutations in class I β -tubulin are unlikely to be a clinically relevant cause of drug resistance.

Sowers, R., J. Toguchida, et al. (2003). "mRNA Expression Levels of E2F Transcription Factors Correlate with Dihydrofolate Reductase, Reduced Folate Carrier, and Thymidylate Synthase mRNA Expression in Osteosarcoma." *Mol. Cancer Ther.* **2**(6): 535-541.

<http://mct.aacrjournals.org/cgi/content/abstract/2/6/535>

Previous studies have shown that decreased expression of the reduced folate carrier (RFC) and increased expression of dihydrofolate reductase (DHFR) are associated with intrinsic and acquired methotrexate resistance, respectively, in osteosarcoma (OS). It has also been shown in colorectal cancer that E2F-1 expression correlates with thymidylate synthase (TS) and, to a lesser extent, DHFR expression. To begin to investigate the regulation of DHFR and RFC expression in OS samples, mRNA expression of E2F-1 and E2F-4 were measured in OS tumor samples and related to DHFR, RFC, and TS mRNA expression. Using fluorescent quantitative real-time PCR, 112 human OS patient samples were investigated for potential E2F-1/E2F-4:DHFR, E2F-1/E2F-4:RFC, and E2F-1/E2F-4:TS correlations. The expression ranges for each gene are as follows: DHFR, 0.02-33.13 (median = 0.20); RFC, 0.02-229.13 (median = 1.91); TS, 0.01-9.99 (median = 0.15); E2F-1, 0.05-69.07 (median = 0.52); and E2F-4, 0.24-52.35 (median = 1.45). Spearman correlation coefficients (rs) for E2F-1:DHFR, E2F-1:RFC, E2F-1:TS, E2F-4:DHFR, E2F-4:RFC, and E2F-4:TS were calculated to be 0.53, 0.63, 0.60, 0.41, 0.58, and 0.33, respectively (P < 0.001). On the basis of this data, moderate correlations exist between E2F-1/E2F-4 and DHFR, RFC, and TS. These results suggest E2F-1/E2F-4 may play a role in the regulation of RFC expression, which has not been reported previously. The E2F transcription factors are also related to DHFR and TS expression in OS samples, suggesting a possible involvement in methotrexate resistance. Although E2F mRNA levels correlate with DHFR, RFC, and TS mRNA expression, additional experiments are necessary to determine the direct effects of these transcription factors and identify other proteins that may influence this relationship.

Baldwin, M. E., M. M. Halford, et al. (2005). "Vascular Endothelial Growth Factor D Is Dispensable for Development of the Lymphatic System." Mol. Cell. Biol. **25**(6): 2441-2449.

<http://mcb.asm.org/cgi/content/abstract/25/6/2441>

Vascular endothelial growth factor receptor 3 (Vegfr-3) is a tyrosine kinase that is expressed on the lymphatic endothelium and that signals for the growth of the lymphatic vessels (lymphangiogenesis). Vegf-d, a secreted glycoprotein, is one of two known activating ligands for Vegfr-3, the other being Vegf-c. Vegf-d stimulates lymphangiogenesis in tissues and tumors; however, its role in embryonic development was previously unknown. Here we report the generation and analysis of mutant mice deficient for Vegf-d. Vegf-d-deficient mice were healthy and fertile, had normal body mass, and displayed no pathologic changes consistent with a defect in lymphatic function. The lungs, sites of strong Vegf-d gene expression during embryogenesis in wild-type mice, were normal in Vegf-d-deficient mice with respect to tissue mass and morphology, except that the abundance of the lymphatics adjacent to bronchioles was slightly reduced. Dye uptake experiments indicated that large lymphatics under the skin were present in normal locations and were functional. Smaller dermal lymphatics were similar in number, location, and function to those in wild-type controls. The lack of a profound lymphatic phenotype in Vegf-d-deficient mice suggests that Vegf-d does not play a major role in lymphatic development or that Vegf-c or another, as-yet-unknown activating Vegfr-3 ligand can compensate for Vegf-d during development.

Bhattacharyya, S. N., S. Chatterjee, et al. (2002). "Mitochondrial RNA Import in *Leishmania tropica*: Aptamers Homologous to Multiple tRNA Domains That Interact Cooperatively or Antagonistically at the Inner Membrane." Mol. Cell. Biol. **22**(12): 4372-4382.

<http://mcb.asm.org/cgi/content/abstract/22/12/4372>

A large number of cytoplasmic tRNAs are imported into the kinetoplast-mitochondrion of *Leishmania* by a receptor-mediated process. To identify the sequences recognized by import receptors, mitochondria were incubated with a combinatorial RNA library. Repeated cycles of amplification of the imported sequences (SELEX) resulted in rapid selection of several import aptamers containing sequence motifs present in the anticodon arm, the D arm, the V-T region, and acceptor stem of known tRNAs, confirming or suggesting the presence of import signals in these domains. As predicted, truncated derivatives of tRNA^{Ala}(UAU) containing the D arm or the V-T region were imported in vitro. Four aptamers were studied in detail. All were imported in vitro as well as in transiently transfected cells, using the same pathway as tRNA, but their individual import efficiencies were different. Two types of aptamers were discernible: the A arm and D arm homologues (type I), which were efficiently transferred across the inner mitochondrial membrane, and the V-T homologues (type II), which were not. Remarkably, subnanomolar concentrations of type I RNAs stimulated the entry of type II RNAs into the matrix, whereas type II RNAs inhibited inner membrane transfer of type I RNAs. Moreover, tRNA^{Tyr}(GUA) and tRNA^{Ala}(UAU) interacted with one another as type I and type II, respectively. Such cooperative and antagonistic interactions may allow the use of a limited number of receptors to recognize a large number of tRNAs of variable affinity and enable the maintenance of a properly balanced tRNA pool for mitochondrial translation.

Cao, S., H. Bendall, et al. (2003). "The High-Mobility-Group Box Protein SSRP1/T160 Is Essential for Cell Viability in Day 3.5 Mouse Embryos." Mol. Cell. Biol. **23**(15): 5301-5307.

<http://mcb.asm.org/cgi/content/abstract/23/15/5301>

The high-mobility-group (HMG) SSRP1 protein is a member of a conserved chromatin-remodeling complex (FACT/DUF/CP) implicated in DNA replication, basal and regulated transcription, and DNA repair. To assist in the functional analysis of SSRP1, the *Ssrp1* gene was targeted in murine embryonic stem cells, and the mutation was introduced into the germ line. Embryos homozygous for the targeted allele die soon after implantation, and preimplantation blastocysts are defective for cell outgrowth and/or survival in vitro. The *Ssrp1* mutation was also crossed into a p53 null background without affecting growth and/or survival defects caused by loss of *Ssrp1* function. Thus, *Ssrp1* appears to encode nonredundant and p53-independent functions that are essential for cell viability.

Catalanotto, C., M. Pallotta, et al. (2004). "Redundancy of the Two Dicer Genes in Transgene-Induced Posttranscriptional Gene Silencing in *Neurospora crassa*." *Mol. Cell. Biol.* **24**(6): 2536-2545.

<http://mcb.asm.org/cgi/content/abstract/24/6/2536>

RNA interference (RNAi) in animals, cosuppression in plants, and quelling in fungi are homology-dependent gene silencing mechanisms in which the introduction of either double-stranded RNA (dsRNA) or transgenes induces sequence-specific mRNA degradation. These phenomena share a common genetic and mechanistic basis. The accumulation of short interfering RNA (siRNA) molecules that guide sequence-specific mRNA degradation is a common feature in both silencing mechanisms, as is the component of the RNase complex involved in mRNA cleavage. During RNAi in animal cells, dsRNA is processed into siRNA by an RNase III enzyme called Dicer. Here we show that elimination of the activity of two Dicer-like genes by mutation in the fungus *Neurospora crassa* eliminates transgene-induced gene silencing (quelling) and the processing of dsRNA to an siRNA form. The two Dicer-like genes appear redundant because single mutants are quelling proficient. This first demonstration of the involvement of Dicer in gene silencing induced by transgenes supports a model by which a dsRNA produced by the activity of cellular RNA-dependent RNA polymerases on transgenic transcripts is an essential intermediate of silencing.

Cazalla, D., K. Newton, et al. (2005). "A Novel SR-Related Protein Is Required for the Second Step of Pre-mRNA Splicing." *Mol. Cell. Biol.* **25**(8): 2969-2980.

<http://mcb.asm.org/cgi/content/abstract/25/8/2969>

The SR family proteins and SR-related polypeptides are important regulators of pre-mRNA splicing. A novel SR-related protein of an apparent molecular mass of 53 kDa was isolated in a gene trap screen that identifies proteins which localize to the nuclear speckles. This novel protein possesses an arginine- and serine-rich domain and was termed SRp53 (for SR-related protein of 53 kDa). In support for a role of this novel RS-containing protein in pre-mRNA splicing, we identified the mouse ortholog of the *Saccharomyces cerevisiae* U1 snRNP-specific protein Luc7p and the U2AF65-related factor HCC1 as interacting proteins. In addition, SRp53 is able to interact with some members of the SR family of proteins and with U2AF35 in a yeast two-hybrid system and in cell extracts. We show that in HeLa nuclear extracts immunodepleted of SRp53, the second step of pre-mRNA splicing is blocked, and recombinant SRp53 is able to restore splicing activity. SRp53 also regulates alternative splicing in a concentration-dependent manner. Taken together, these results suggest that SRp53 is a novel SR-related protein that has a role both in constitutive and in alternative splicing.

Chiang, Y. J., M. T. Hemann, et al. (2004). "Expression of Telomerase RNA Template, but Not Telomerase Reverse Transcriptase, Is Limiting for Telomere Length Maintenance In Vivo." Mol. Cell. Biol. **24**(16): 7024-7031.

<http://mcb.asm.org/cgi/content/abstract/24/16/7024>

Telomerase consists of two essential components, the telomerase RNA template (TR) and telomerase reverse transcriptase (TERT). The haplo-insufficiency of TR was recently shown to cause one form of human dyskeratosis congenita, an inherited disease marked by abnormal telomere shortening. Consistent with this finding, we recently reported that mice heterozygous for inactivation of mouse TR exhibit a similar haplo-insufficiency and are deficient in the ability to elongate telomeres in vivo. To further assess the genetic regulation of telomerase activity, we have compared the abilities of TR-deficient and TERT-deficient mice to maintain or elongate telomeres in interspecies crosses. Homozygous TERT knockout mice had no telomerase activity and failed to maintain telomere length. In contrast, TERT+/- heterozygotes had no detectable defect in telomere elongation compared to wild-type controls, whereas TR+/- heterozygotes were deficient in telomere elongation. Levels of TERT mRNA in heterozygous mice were one-third to one-half the levels expressed in wild-type mice, similar to the reductions in telomerase RNA observed in TR heterozygotes. These findings indicate that both TR and TERT are essential for telomere maintenance and elongation but that gene copy number and transcriptional regulation of TR, but not TERT, are limiting for telomerase activity under the in vivo conditions analyzed.

Daley, J. M. and T. E. Wilson (2005). "Rejoining of DNA Double-Strand Breaks as a Function of Overhang Length." Mol. Cell. Biol. **25**(3): 896-906.

<http://mcb.asm.org/cgi/content/abstract/25/3/896>

The ends of spontaneously occurring double-strand breaks (DSBs) may contain various lengths of single-stranded DNA, blocking lesions, and gaps and flaps generated by end annealing. To investigate the processing of such structures, we developed an assay in which annealed oligonucleotides are ligated onto the ends of a linearized plasmid which is then transformed into *Saccharomyces cerevisiae*. Reconstitution of a marker occurs only when the oligonucleotides are incorporated and repair is in frame, permitting rapid analysis of complex DSB ends. Here, we created DSBs with compatible overhangs of various lengths and asked which pathways are required for their precise repair. Three mechanisms of rejoining were observed, regardless of overhang polarity: nonhomologous end joining (NHEJ), a Rad52-dependent single-strand annealing-like pathway, and a third mechanism independent of the first two mechanisms. DSBs with overhangs of less than 4 bases were mainly repaired by NHEJ. Repair became less dependent on NHEJ when the overhangs were longer or had a higher GC content. Repair of overhangs greater than 8 nucleotides was as much as 150-fold more efficient, impaired 10-fold by rad52 mutation, and highly accurate. Reducing the microhomology extent between long overhangs reduced their repair dramatically, to less than NHEJ of comparable short overhangs. These data support a model in which annealing energy is a primary determinant of the rejoining efficiency and mechanism.

de la Serna, I. L., Y. Ohkawa, et al. (2005). "MyoD Targets Chromatin Remodeling Complexes to the Myogenin Locus Prior to Forming a Stable DNA-Bound Complex." Mol. Cell. Biol. **25**(10): 3997-4009.

<http://mcb.asm.org/cgi/content/abstract/25/10/3997>

The activation of muscle-specific gene expression requires the coordinated action of muscle regulatory proteins and chromatin-remodeling enzymes. Microarray analysis performed in the presence or absence of a dominant-negative BRG1 ATPase demonstrated that approximately one-third of MyoD-induced genes were highly dependent on SWI/SNF enzymes. To understand the mechanism of activation, we performed chromatin immunoprecipitations analyzing the myogenin promoter. We found that H4 hyperacetylation preceded Brg1 binding in a MyoD-dependent manner but that MyoD binding occurred subsequent to H4 modification and Brg1 interaction. In the absence of functional SWI/SNF enzymes, muscle regulatory proteins did not bind to the myogenin promoter, thereby providing evidence for SWI/SNF-dependent activator binding. We observed that the homeodomain factor Pbx1, which cooperates with MyoD to stimulate myogenin expression, is constitutively bound to the myogenin promoter in a SWI/SNF-independent manner, suggesting a two-step mechanism in which MyoD initially interacts indirectly with the myogenin promoter and attracts chromatin-remodeling enzymes, which then facilitate direct binding by MyoD and other regulatory proteins.

Delaloy, C., J. Lu, et al. (2003). "Multiple Promoters in the WNK1 Gene: One Controls Expression of a Kidney-Specific Kinase-Defective Isoform." Mol. Cell. Biol. **23**(24): 9208-9221.

<http://mcb.asm.org/cgi/content/abstract/23/24/9208>

WNK1 is a serine-threonine kinase, the expression of which is affected in pseudohypoaldosteronism type II, a Mendelian form of arterial hypertension. We characterized human WNK1 transcripts to determine the molecular mechanisms governing WNK1 expression. We report the presence of two promoters generating two WNK1 isoforms with a complete kinase domain. Further variations are achieved by the use of two polyadenylation sites and tissue-specific splicing. We also determined the structure of a kidney-specific isoform regulated by a third promoter and starting at a novel exon. This transcript is kinase defective and has a predominant expression in the kidney compared to the other WNK1 isoforms, with, furthermore, a highly restricted expression profile in the distal convoluted tubule. We confirmed that the ubiquitous and kidney-specific promoters are functional in several cells lines and identified core promoters and regulatory elements. In particular, a strong enhancer element upstream from the kidney-specific exon seems specific to renal epithelial cells. Thus, control of human WNK1 gene expression of kinase-active or -deficient isoforms is mediated predominantly through the use of multiple transcription initiation sites and tissue-specific regulatory elements.

Dunty, J. M., V. Gabarra-Niecko, et al. (2004). "FERM Domain Interaction Promotes FAK Signaling." Mol. Cell. Biol. **24**(12): 5353-5368.

<http://mcb.asm.org/cgi/content/abstract/24/12/5353>

From the results of deletion analyses, the FERM domain of FAK has been proposed to inhibit enzymatic activity and repress FAK signaling. We have identified a sequence in the FERM domain that is important for FAK signaling in vivo. Point mutations in this sequence had little effect upon catalytic activity in vitro. However, the mutant exhibits reduced tyrosine phosphorylation and dramatically reduced Src family kinase binding. Further, the abilities of the mutant to transduce biochemical signals and to promote cell migration were severely impaired. The results implicate a FERM domain interaction in cell adhesion-dependent activation of FAK and downstream signaling. We also show that the purified FERM domain of FAK interacts with full-length FAK in vitro, and mutation of this sequence disrupts the interaction. These findings are discussed in the context of models of FAK regulation by its FERM domain.

Edelstein, L. C., L. Lagos, et al. (2003). "NF- κ B-Dependent Assembly of an Enhanceosome-Like Complex on the Promoter Region of Apoptosis Inhibitor Bfl-1/A1." Mol. Cell. Biol. **23**(8): 2749-2761.

<http://mcb.asm.org/cgi/content/abstract/23/8/2749>

Expression of the prosurvival Bcl-2 homologue Bfl-1/A1 is induced by NF- κ B-activating stimuli, while B and T cells from c-rel knockout mice show an absolute defect in bfl-1/a1 gene activation. Here, we demonstrate NF- κ B-dependent assembly of an enhanceosome-like complex on the promoter region of bfl-1. Binding of NF- κ B subunit c-Rel to DNA nucleated the concerted binding of transcription factors AP-1 and C/EBP β to the 5'-regulatory region of bfl-1. Optimal stability of the complex was dependent on proper orientation and phasing of the NF- κ B site. Chromatin immunoprecipitation analyses demonstrated that T-cell activation triggers in vivo binding of endogenous c-Rel, c-Jun, C/EBP β , and HMG-IC to the bfl-1 regulatory region, coincident with selective recruitment of coactivators TAFII250 and p300, SWI/SNF chromatin remodeling factor component BRG-1, and basal transcription factors TATA-binding protein (TBP) and TFIIB, as well as hyperacetylation of histones H3 and H4. These results highlight a critical role for NF- κ B in bfl-1 transcription and point to the need for a complex and precise regulatory network to control bfl-1 expression. To our knowledge, this is the first demonstration of enhanceosome-mediated regulation of a cell death inhibitor.

Gonzalez-Suarez, E., J. M. Flores, et al. (2002). "Cooperation between p53 Mutation and High Telomerase Transgenic Expression in Spontaneous Cancer Development." Mol. Cell. Biol. **22**(20): 7291-7301.

<http://mcb.asm.org/cgi/content/abstract/22/20/7291>

Telomerase reintroduction in adult somatic tissues is envisioned as a way to extend their proliferative capacity. It is still a question, however, whether constitutive telomerase expression in adult tissues impacts the normal aging and spontaneous cancer incidence of an organism. Here, we studied the aging and spontaneous cancer incidence of mice with transgenic telomerase expression in a wide range of adult tissues, K5-Tert mice. For this, we maintained large colonies of K5-Tert mice for more than 2 years. K5-Tert mice showed a decreased life span compared to wild-type cohorts associated with a higher incidence of preneoplastic and neoplastic lesions in various tissue types. Neoplasias in K5-Tert mice were coincident with transgene expression in the affected tissues. These observations suggest that high telomerase activity may cooperate with genetic alterations that occur with age to promote tumorigenesis. Indeed, we demonstrate here that increased cancer incidence and the reduced viability of K5-Tert mice are aggravated in a p53 $\pm$ genetic background, indicating that telomerase cooperates with loss of p53 function in inducing tumorigenesis. Altogether, these results demonstrate that constitutive high levels of telomerase activity result in a decreased life span associated with an increased incidence of neoplasias as the organism ages.

Hermoso, M. A., T. Matsuguchi, et al. (2004). "Glucocorticoids and Tumor Necrosis Factor Alpha Cooperatively Regulate Toll-Like Receptor 2 Gene Expression." Mol. Cell. Biol. **24**(11): 4743-4756.

<http://mcb.asm.org/cgi/content/abstract/24/11/4743>

Tumor necrosis factor alpha (TNF- α) and glucocorticoids are widely recognized as mutually antagonistic regulators of adaptive immunity and inflammation. Surprisingly, we show here that they cooperatively regulate components of innate immunity. The Toll-like receptor 2 (TLR2) gene encodes a transmembrane receptor critical for triggering innate immunity. Although TLR2 mRNA and protein are induced by inflammatory molecules such as TNF- α , we show that TLR2 is also induced by the anti-inflammatory glucocorticoids in cells where they also regulate MKP-1 mRNA and protein levels. TNF- α and glucocorticoids cooperate to regulate the TLR2 promoter, through the involvement of a 3' NF- κ B site, a STAT-binding element, and a 3' glucocorticoid response element (GRE). Molecular studies show that the κ B α superrepressor or a STAT dominant negative element prevented TNF- α and dexamethasone stimulation of TLR2 promoter. Similarly, an AF-1 deletion mutant of glucocorticoid receptor or ablation of a putative GRE notably reduced the cooperative regulation of TLR2. Using chromatin immunoprecipitation assays, we demonstrate that all three transcription factors interact with both endogenous and transfected TLR2 promoters after stimulation by TNF- α and dexamethasone. Together, these studies define novel signaling mechanism for these three transcription factors, with a profound impact on discrimination of innate and adaptive immune responses.

Irvine, R. A., I. G. Lin, et al. (2002). "DNA Methylation Has a Local Effect on Transcription and Histone Acetylation." *Mol. Cell. Biol.* **22**(19): 6689-6696.

<http://mcb.asm.org/cgi/content/abstract/22/19/6689>

DNA methylation is commonly associated with gene silencing, and a link between histone deacetylation and DNA methylation has been established. However, the transcriptional impact of the position and length of methylated zones relative to the promoter and the coding region of a gene remains quite unclear. This study investigates the impact of regional methylation on transcription and the relationship between DNA methylation and histone acetylation. Using patch-methylated stable episomes in human cells, we establish the pivotal importance of the location of DNA methylation in the regulation of transcription. We further demonstrate that the size of the methylated patch is not a key determinant for transcriptional suppression. The impact of DNA methylation on transcription is greater when it is in the transcription unit, and it is primarily a local effect. However, methylation outside of the transcription unit may potentiate the effect of methylation within the transcription unit. Acetylated histones are associated with unmethylated DNA and are nearly absent from methylated DNA regions. This association appears to be local and does not propagate along the DNA.

Kang, S.-H. L., C. Mione Kiefer, et al. (2003). "Role of the Promoter in Maintaining Transcriptionally Active Chromatin Structure and DNA Methylation Patterns In Vivo." *Mol. Cell. Biol.* **23**(12): 4150-4161.

<http://mcb.asm.org/cgi/content/abstract/23/12/4150>

Establishment and maintenance of differential chromatin structure between transcriptionally competent and repressed genes are critical aspects of transcriptional regulation. The elements and mechanisms that mediate formation and maintenance of these chromatin states in vivo are not well understood. To examine the role of the promoter in maintaining chromatin structure and DNA methylation patterns of the transcriptionally active X-linked HPRT locus, 323 bp of the endogenous human HPRT promoter (from position -222 to +102 relative to the translation start site) was replaced by plasmid sequences by homologous recombination in cultured HT-1080 male fibrosarcoma cells. The targeted cells, which showed no detectable HPRT transcription, were then assayed for effects on DNase I hypersensitivity, general DNase I sensitivity, and DNA methylation patterns across the HPRT locus. In cells carrying the deletion, significantly

diminished DNase I hypersensitivity in the 5' flanking region was observed compared to that in parental HT-1080 cells. However, general DNase I sensitivity and DNA methylation patterns were found to be very similar in the mutated cells and in the parental cells. These findings suggest that the promoter and active transcription play a relatively limited role in maintaining transcriptionally potentiated epigenetic states.

Karlseder, J., L. Kachatrian, et al. (2003). "Targeted Deletion Reveals an Essential Function for the Telomere Length Regulator Trf1." Mol. Cell. Biol. **23**(18): 6533-6541.

<http://mcb.asm.org/cgi/content/abstract/23/18/6533>

The human telomeric DNA binding factor TRF1 (hTRF1) and its interacting proteins TIN2, tankyrase 1 and 2, and PINX1 have been implicated in the regulation of telomerase-dependent telomere length maintenance. Here we show that targeted deletion of exon 1 of the mouse gene encoding Trf1 causes early (day 5 to 6 postcoitus) embryonic lethality. The absence of telomerase did not alter the Terf1ex1{Delta}/ex1{Delta} lethality, indicating that the phenotype was not due to inappropriate telomere elongation by telomerase. Terf1ex1{Delta}/ex1{Delta} blastocysts had a severe growth defect of the inner cell mass that was accompanied by apoptosis. However, no evidence was found for telomere uncapping causing this cell death; chromosome spreads of Terf1ex1{Delta}/ex1{Delta} blastocysts did not reveal chromosome end-to-end fusions, and p53 deficiency only briefly delayed Terf1ex1{Delta}/ex1{Delta} lethality. These data suggest that murine Trf1 has an essential function that is independent of telomere length regulation.

Kirito, K., N. Fox, et al. (2004). "Thrombopoietin Induces HOXA9 Nuclear Transport in Immature Hematopoietic Cells: Potential Mechanism by Which the Hormone Favorably Affects Hematopoietic Stem Cells." Mol. Cell. Biol. **24**(15): 6751-6762.

<http://mcb.asm.org/cgi/content/abstract/24/15/6751>

Members of the homeobox family of transcription factors are major regulators of hematopoiesis. Overexpression of either HOXB4 or HOXA9 in primitive marrow cells enhances the expansion of hematopoietic stem cells (HSCs). However, little is known of how expression or function of these proteins is regulated during hematopoiesis under physiological conditions. In our previous studies we demonstrated that thrombopoietin (TPO) enhances levels of HOXB4 mRNA in primitive hematopoietic cells (K. Kirito, N. Fox, and K. Kaushansky, Blood 102:3172-3178, 2003). To extend our studies, we investigated the effects of TPO on HOXA9 in this same cell population. Although overall levels of the transcription factor were not affected, we found that TPO induced the nuclear import of HOXA9 both in UT-7/TPO cells and in primitive Sca-1+/c-kit+/Gr-1- hematopoietic cells in a mitogen-activated protein kinase-dependent fashion. TPO also controlled MEIS1 expression at mRNA levels, at least in part due to phosphatidylinositol 3-kinase activation. Collectively, TPO modulates the function of HOXA9 by leading to its nuclear translocation, likely mediated by effects on its partner protein MEIS1, and potentially due to two newly identified nuclear localization signals. Our data suggest that TPO controls HSC development through the regulation of multiple members of the Hox family of transcription factors through multiple mechanisms.

Kurisaki, K., A. Kurisaki, et al. (2003). "Nuclear Factor YY1 Inhibits Transforming Growth Factor {beta}- and Bone Morphogenetic Protein-Induced Cell Differentiation." Mol. Cell. Biol. **23**(13): 4494-4510.

<http://mcb.asm.org/cgi/content/abstract/23/13/4494>

Smad proteins transduce transforming growth factor β (TGF- β) and bone morphogenetic protein (BMP) signals that regulate cell growth and differentiation. We have identified YY1, a transcription factor that positively or negatively regulates transcription of many genes, as a novel Smad-interacting protein. YY1 represses the induction of immediate-early genes to TGF- β and BMP, such as the plasminogen activator inhibitor 1 gene (PAI-1) and the inhibitor of differentiation/inhibitor of DNA binding 1 gene (Id-1). YY1 inhibits binding of Smads to their cognate DNA elements in vitro and blocks Smad recruitment to the Smad-binding element-rich region of the PAI-1 promoter in vivo. YY1 interacts with the conserved N-terminal Mad homology 1 domain of Smad4 and to a lesser extent with Smad1, Smad2, and Smad3. The YY1 zinc finger domain mediates the association with Smads and is necessary for the repressive effect of YY1 on Smad transcriptional activity. Moreover, downregulation of endogenous YY1 by antisense and small interfering RNA strategies results in enhanced transcriptional responses to TGF- β or BMP. Ectopic expression of YY1 inhibits, while knockdown of endogenous YY1 enhances, TGF- β - and BMP-induced cell differentiation. In contrast, overexpression or knockdown of YY1 does not affect growth inhibition induced by TGF- β or BMP. Accordingly, YY1 does not interfere with the regulation of immediate-early genes involved in the TGF- β growth-inhibitory response, the cell cycle inhibitors p15 and p21, and the proto-oncogene c-myc. In conclusion, YY1 represses Smad transcriptional activities in a gene-specific manner and thus regulates cell differentiation induced by TGF- β superfamily pathways.

Lamia, K. A., O. D. Peroni, et al. (2004). "Increased Insulin Sensitivity and Reduced Adiposity in Phosphatidylinositol 5-Phosphate 4-Kinase β -/- Mice." *Mol. Cell. Biol.* **24**(11): 5080-5087.

<http://mcb.asm.org/cgi/content/abstract/24/11/5080>

Phosphorylated derivatives of the lipid phosphatidylinositol are known to play critical roles in insulin response. Phosphatidylinositol 5-phosphate 4-kinases convert phosphatidylinositol 5-phosphate to phosphatidylinositol 4,5-bis-phosphate. To understand the physiological role of these kinases, we generated mice that do not express phosphatidylinositol 5-phosphate 4-kinase β . These mice are hypersensitive to insulin and have reduced body weights compared to wild-type littermates. While adult male mice lacking phosphatidylinositol 5-phosphate 4-kinase β have significantly less body fat than wild-type littermates, female mice lacking phosphatidylinositol 5-phosphate 4-kinase β have increased insulin sensitivity in the presence of normal adiposity. Furthermore, in vivo insulin-induced activation of the protein kinase Akt is enhanced in skeletal muscle and liver from mice lacking phosphatidylinositol 5-phosphate 4-kinase β . These results indicate that phosphatidylinositol 5-phosphate 4-kinase β plays a role in determining insulin sensitivity and adiposity in vivo and suggest that inhibitors of this enzyme may be useful in the treatment of type 2 diabetes.

Lanz, R. B., S. S. Chua, et al. (2003). "Steroid Receptor RNA Activator Stimulates Proliferation as Well as Apoptosis In Vivo." *Mol. Cell. Biol.* **23**(20): 7163-7176.

<http://mcb.asm.org/cgi/content/abstract/23/20/7163>

Steroid receptor RNA activator (SRA) is an RNA that coactivates steroid hormone receptor-mediated transcription in vitro. Its expression is strongly up-regulated in many human tumors of the breast, uterus, and ovary, suggesting a potential role in pathogenesis. To assess SRA function in vivo, a transgenic-mouse model was generated to enable robust human SRA expression by using the transcriptional activity of the mouse mammary tumor virus long terminal

repeat. Transgenic SRA was expressed in the nuclei of luminal epithelial cells of the mammary gland and tissues of the male accessory sex glands. Distinctive evidence for SRA function in vivo was obtained from the elevated levels of estrogen-controlled expression of progesterone receptor in transgenic mammary glands. Although overexpression of SRA showed strong promoting activities on cellular proliferation and differentiation, no alterations progressed to malignancy. Epithelial hyperplasia was accompanied by increased apoptosis, and preneoplastic lesions were cleared by focal degenerative transformations. In bitransgenic mice, SRA also antagonized ras-induced tumor formation. This work indicates that although coactivation of steroid-dependent transcription by SRA is accompanied by a proliferative response, overexpression is not in itself sufficient to induce tumorigenesis. Our results underline an intricate relationship between the different physiological roles of steroid receptors in conjunction with the RNA activator in the regulation of development, tissue homeostasis, and reproduction.

Le Cam, L., M. Lacroix, et al. (2004). "The E4F Protein Is Required for Mitotic Progression during Embryonic Cell Cycles." Mol. Cell. Biol. **24**(14): 6467-6475.

<http://mcb.asm.org/cgi/content/abstract/24/14/6467>

The ubiquitously expressed E4F protein was originally identified as an E1A-regulated cellular transcription factor required for adenovirus replication. The function of this protein in normal cell physiology remains largely unknown. To address this issue, we generated E4F knockout mice by gene targeting. Embryos lacking E4F die at the peri-implantation stage, while in vitro-cultured E4F^{-/-} blastocysts exhibit defects in mitotic progression, chromosomal missegregation, and increased apoptosis. Consistent with these observations, we found that E4F localizes to the mitotic spindle during the M phase of early embryos. Our results establish a crucial role for E4F during early embryonic cell cycles and reveal an unexpected function for E4F in mitosis.

Lee, S. J., G. Gonzalez-Aseguinolaza, et al. (2002). "Disseminated Candidiasis and Hepatic Malarial Infection in Mannose-Binding-Lectin-A-Deficient Mice." Mol. Cell. Biol. **22**(23): 8199-8203.

<http://mcb.asm.org/cgi/content/abstract/22/23/8199>

To examine the physiological functions of mannose-binding lectin A (MBL-A), we generated mice that were deficient in MBL-A and examined their susceptibilities to the microbial pathogens *Candida albicans* and *Plasmodium yoelii*, an accepted experimental malaria model in mouse. We found no differences in the survival rates and fungal burdens of wild-type and MBL-A^{-/-} mice with disseminated *C. albicans* infection. The two mouse strains were also similar in their abilities to resist hepatic accumulation of *P. yoelii* parasites. We conclude that MBL-A deficiency does not alter resistance to disseminated candidiasis or initial hepatic invasion by *P. yoelii*.

Maier, H., J. Colbert, et al. (2003). "Activation of the Early B-Cell-Specific mb-1 (Ig- α) Gene by Pax-5 Is Dependent on an Unmethylated Ets Binding Site." Mol. Cell. Biol. **23**(6): 1946-1960.

<http://mcb.asm.org/cgi/content/abstract/23/6/1946>

Methylation of cytosine in CpG dinucleotides promotes transcriptional repression in mammals by blocking transcription factor binding and recruiting methyl-binding proteins that initiate chromatin remodeling. Here, we use a novel cell-based system to show that retrovirally expressed Pax-5 protein activates endogenous early B-cell-specific mb-1 genes in plasmacytoma cells, but only

when the promoter is hypomethylated. CpG methylation does not directly affect binding of the promoter by Pax-5. Instead, methylation of an adjacent CpG interferes with assembly of ternary complexes comprising Pax-5 and Ets proteins. In electrophoretic mobility shift assays, recruitment of Ets-1 is blocked by methylation of the Ets site (5'CCGGAG) on the antisense strand. In transfection assays, selective methylation of a single CpG within the Pax-5-dependent Ets site greatly reduces mb-1 promoter activity. Prior demethylation of the endogenous mb-1 promoter is required for its activation by Pax-5 in transduced cells. Although B-lineage cells have only unmethylated mb-1 genes and do not modulate methylation of the mb-1 promoter during development, other tissues feature high percentages of methylated alleles. Together, these studies demonstrate a novel DNA methylation-dependent mechanism for regulating transcriptional activity through the inhibition of DNA-dependent protein-protein interactions.

Martens, J. H. A., M. Verlaan, et al. (2002). "Scaffold/Matrix Attachment Region Elements Interact with a p300-Scaffold Attachment Factor A Complex and Are Bound by Acetylated Nucleosomes." Mol. Cell. Biol. **22**(8): 2598-2606.

<http://mcb.asm.org/cgi/content/abstract/22/8/2598>

The transcriptional coactivator p300 regulates transcription by binding to proteins involved in transcription and by acetylating histones and other proteins. These transcriptional effects are mainly at promoter and enhancer elements. Regulation of transcription also occurs through scaffold/matrix attachment regions (S/MARs), the chromatin regions that bind the nuclear matrix. Here we show that p300 binds to the S/MAR binding protein scaffold attachment factor A (SAF-A), a major constituent of the nuclear matrix. Using chromatin immunoprecipitations, we established that both p300 and SAF-A bind to S/MAR elements in the transiently silent topoisomerase I gene prior to its activation at G1 during cell cycle. This binding is accompanied by local acetylation of nucleosomes, suggesting that p300-SAF-A interactions at S/MAR elements of nontranscribed genes might poise these genes for transcription.

Martens, J. H. A., M. Verlaan, et al. (2003). "Cascade of Distinct Histone Modifications during Collagenase Gene Activation." Mol. Cell. Biol. **23**(5): 1808-1816.

<http://mcb.asm.org/cgi/content/abstract/23/5/1808>

Gene activation in eukaryotes requires chromatin remodeling, in part via histone modifications. To study the events at the promoter of a mitogen-inducible gene, we examined the induction of expression of the collagenase gene. It has been established that the collagenase gene can be activated by c-Jun and c-Fos and that the transcriptional coactivator p300 is involved in the activation. As expected, we found histone acetyltransferase activity at the collagenase promoter during activation. Interestingly, we also found histone methyltransferase and kinase activity. Strikingly, the first modification observed is methylation of histone H3 lysine 4, which correlates with the binding of the SET9 methyltransferase and the assembly of a complex consisting of c-Jun, c-Fos, TATA binding protein, and RNA polymerase II. The assembly of the preinitiation complex also shows an ordered binding of the acetyltransferase p300, the RSK2 kinase, and the SWI/SNF component Brg-1. Our results suggest that collagenase gene activation involves a dynamic recruitment of different factors and that in addition to acetylation, histone H3 lysine 4 di- and trimethylation and histone H3 serine 10 phosphorylation are important steps in the activation of this gene.

Narisawa, S., N. B. Hecht, et al. (2002). "Testis-Specific Cytochrome c-Null Mice Produce Functional Sperm but Undergo Early Testicular Atrophy." Mol. Cell. Biol. **22**(15): 5554-5562.

<http://mcb.asm.org/cgi/content/abstract/22/15/5554>

Differentiating male germ cells express a testis-specific form of cytochrome c (Cyt cT) that is distinct from the cytochrome c expressed in somatic cells (Cyt cS). To examine the role of Cyt cT in germ cells, we generated mice null for Cyt cT. Homozygous Cyt cT^{-/-} pups were statistically underrepresented (21%) but developed normally and were fertile. However, spermatozoa isolated from the cauda epididymis of Cyt cT-null animals were less effective in fertilizing oocytes in vitro and contain reduced levels of ATP compared to wild-type sperm. Sperm from Cyt cT-null mice contained a greater number of immotile spermatozoa than did samples from control mice, i.e., 53.1% {+/-} 13.7% versus 33.2% {+/-} 10.3% ($P < 0.0001$) for vas deferens sperm and 40.1% {+/-} 9.6% versus 33.2% {+/-} 7.5% ($P = 0.0104$) for epididymal sperm. Cyt cT-null mice often exhibit early atrophy of the testes after 4 months of age, losing germ cells as a result of increased apoptosis. However, no difference in the activation of caspase-3, -8, or -9 was detected between the Cyt cT^{-/-} testes and controls. Our data indicate that the Cyt cT-null testes undergo early atrophy equivalent to that which occurs during aging as a consequence of a reduction in oxidative phosphorylation.

Park, E. K., N. Warner, et al. (2002). "Low-Molecular-Weight Protein Tyrosine Phosphatase Is a Positive Component of the Fibroblast Growth Factor Receptor Signaling Pathway." Mol. Cell. Biol. **22**(10): 3404-3414.

<http://mcb.asm.org/cgi/content/abstract/22/10/3404>

Low-molecular-weight protein tyrosine phosphatase (LMW-PTP) has been implicated in the regulation of cell growth and actin rearrangement mediated by several receptor tyrosine kinases, including platelet-derived growth factor and epidermal growth factor. Here we identify the *Xenopus laevis* homolog of LMW-PTP1 (XLPTP1) as an additional positive regulator in the fibroblast growth factor (FGF) signaling pathway during *Xenopus* development. XLPTP1 has an expression pattern that displays substantial overlap with FGF receptor 1 (FGFR1) during *Xenopus* development. Using morpholino antisense technology, we show that inhibition of endogenous XLPTP1 expression dramatically restricts anterior and posterior structure development and inhibits mesoderm formation. In ectodermal explants, loss of XLPTP1 expression dramatically blocks the induction of the early mesoderm gene, *Xbra* (*Xbra*), by FGF and partially blocks *Xbra* induction by Activin. Moreover, FGF-induced activation of mitogen-activated protein (MAP) kinase is also inhibited by XLPTP1 morpholino antisense oligonucleotides; however, introduction of RNA encoding XLPTP1 is able to rescue morphological and biochemical effects of antisense inhibition. Inhibition of FGF-induced MAP kinase activity due to loss of XLPTP1 is also rescued by an active Ras, implying that XLPTP1 may act upstream of or parallel to Ras. Finally, XLPTP1 physically associates only with an activated FGFR1, and this interaction requires the presence of SNT1/FRS-2 (FGFR substrate 2). Although LMW-PTP1 has been shown to participate in other receptor systems, the data presented here also reveal XLPTP1 as a new and important component of the FGF signaling pathway.

Prioleau, M.-N., M.-C. Gendron, et al. (2003). "Replication of the Chicken {beta}-Globin Locus: Early-Firing Origins at the 5' HS4 Insulator and the {rho}- and {beta}A-Globin Genes Show Opposite Epigenetic Modifications." Mol. Cell. Biol. **23**(10): 3536-3549.

<http://mcb.asm.org/cgi/content/abstract/23/10/3536>

Chromatin structure is believed to exert a strong effect on replication origin function. We have studied the replication of the chicken β -globin locus, whose chromatin structure has been extensively characterized. This locus is delimited by hypersensitive sites (HSs) that mark the position of insulator elements. A stretch of condensed chromatin and another HS separate the β -globin domain from an adjacent folate receptor (FR) gene. We demonstrate here that in erythroid cells that express the FR but not the globin genes, replication initiates at four sites within the β -globin domain, one at the 5' HS4 insulator and the other three near the ρ - and β A-globin genes. Three origins consist of G+C-rich sequences enriched in CpG dinucleotides. The fourth origin is A+T rich. Together with previous work, these data reveal that the insulator origin has unmethylated CpGs, hyperacetylated histones H3 and H4, and lysine 4-methylated histone H3. In contrast, opposite modifications are observed at the other G+C-rich origins. We also show that the whole region, including the stretch of condensed chromatin, replicates early in S phase in these cells. Therefore, different early-firing origins within the same locus may have opposite patterns of epigenetic modifications. The role of insulator elements in DNA replication is discussed.

Regnier, V., P. Vagnarelli, et al. (2005). "CENP-A Is Required for Accurate Chromosome Segregation and Sustained Kinetochore Association of BubR1." *Mol. Cell. Biol.* **25**(10): 3967-3981.

<http://mcb.asm.org/cgi/content/abstract/25/10/3967>

CENP-A is an evolutionarily conserved, centromere-specific variant of histone H3 that is thought to play a central role in directing kinetochore assembly and in centromere function. Here, we have analyzed the consequences of disrupting the CENP-A gene in the chicken DT40 cell line. In CENP-A-depleted cells, kinetochore protein assembly is impaired, as indicated by mislocalization of the inner kinetochore proteins CENP-I, CENP-H, and CENP-C as well as the outer components Nuf2/Hec1, Mad2, and CENP-E. However, BubR1 and the inner centromere protein INCENP are efficiently recruited to kinetochores. Following CENP-A depletion, chromosomes are deficient in proper congression on the mitotic spindle and there is a transient delay in prometaphase. CENP-A-depleted cells further proceed through anaphase and cytokinesis with unequal chromosome segregation, suggesting that some kinetochore function remains following substantial depletion of CENP-A. We furthermore demonstrate that CENP-A-depleted cells exhibit a specific defect in maintaining kinetochore localization of the checkpoint protein BubR1 under conditions of checkpoint activation. Our data thus point to a specific role for CENP-A in assembly of kinetochores competent in the maintenance of mitotic checkpoint signaling.

Scamborova, P., A. Wong, et al. (2004). "An Intronic Enhancer Regulates Splicing of the Twintron of *Drosophila melanogaster* prospero Pre-mRNA by Two Different Spliceosomes." *Mol. Cell. Biol.* **24**(5): 1855-1869.

<http://mcb.asm.org/cgi/content/abstract/24/5/1855>

We have examined the alternative splicing of the *Drosophila melanogaster* prospero twintron, which contains splice sites for both the U2- and U12-type spliceosome and generates two forms of mRNA, pros-L (U2-type product) and pros-S (U12-type product). We find that twintron splicing is developmentally regulated: pros-L is abundant in early embryogenesis while pros-S displays the opposite pattern. We have established a Kc cell in vitro splicing system that accurately splices a minimal pros substrate containing the twintron and have examined the sequence requirements for pros twintron splicing. Systematic deletion and mutation analysis of intron sequences established that twintron splicing requires a 46-nucleotide purine-rich element located 32 nucleotides downstream of the U2-type 5' splice site. While this element regulates both splicing pathways, its alteration showed the severest effects on the U2-type splicing pathway. Addition of

an RNA competitor containing the wild-type purine-rich element to the Kc extract abolished U2-type splicing and slightly repressed U12-type splicing, suggesting that a trans-acting factor(s) binds the enhancer element to stimulate twintron splicing. Thus, we have identified an intron region critical for prospero twintron splicing as a first step towards elucidating the molecular mechanism of splicing regulation involving competition between the two kinds of spliceosomes.

Schuendeln, M. M., R. P. Piekorz, et al. (2004). "The Centrosomal, Putative Tumor Suppressor Protein TACC2 Is Dispensable for Normal Development, and Deficiency Does Not Lead to Cancer." Mol. Cell. Biol. **24**(14): 6403-6409.

<http://mcb.asm.org/cgi/content/abstract/24/14/6403>

TACC2 is a member of the transforming acidic coiled-coil-containing protein family and is associated with the centrosome-spindle apparatus during cell cycling. In vivo, the TACC2 gene is expressed in various splice forms predominantly in postmitotic tissues, including heart, muscle, kidney, and brain. Studies of human breast cancer samples and cell lines suggest a putative role of TACC2 as a tumor suppressor protein. To analyze the physiological role of TACC2, we generated mice lacking TACC2. TACC2-deficient mice are viable, develop normally, are fertile, and lack phenotypic changes compared to wild-type mice. Furthermore, TACC2 deficiency does not lead to an increased incidence of tumor development. Finally, in TACC2-deficient embryonic fibroblasts, proliferation and cell cycle progression as well as centrosome numbers are comparable to those in wild-type cells. Therefore, TACC2 is not required, nonredundantly, for mouse development and normal cell proliferation and is not a tumor suppressor protein.

Song, S., J. Cooperman, et al. (2004). "Identification of Cyclin D3 as a Direct Target of E2A Using DamID." Mol. Cell. Biol. **24**(19): 8790-8802.

<http://mcb.asm.org/cgi/content/abstract/24/19/8790>

The transcription factor E2A can promote precursor B cell expansion, promote G1 cell cycle progression, and induce the expressions of multiple G1-phase cyclins. To better understand the mechanism by which E2A induces these cyclins, we characterized the relationship between E2A and the cyclin D3 gene promoter. E2A transactivated the 1-kb promoter of cyclin D3, which contains two E boxes. However, deletion of the E boxes did not disrupt the transactivation by E2A, raising the possibility of indirect activation via another transcription factor or binding of E2A to non-E-box DNA elements. To distinguish between these two possibilities, promoter occupancy was examined using the DamID approach. A fusion construct composed of E2A and the Escherichia coli DNA adenosine methyltransferase (E47Dam) was subcloned in lentivirus vectors and used to transduce precursor B-cell and myeloid progenitor cell lines. In both cell types, specific adenosine methylation was identified at the cyclin D3 promoter. Chromatin immunoprecipitation analysis confirmed the DamID findings and localized the binding to within 1 kb of the two E boxes. The methylation by E47Dam was not disrupted by mutations in the E2A portion that block DNA binding. We conclude that E2A can be recruited to the cyclin D3 promoter independently of E boxes or E2A DNA binding activity.

Sorci, G., F. Riuzzi, et al. (2003). "S100B Inhibits Myogenic Differentiation and Myotube Formation in a RAGE-Independent Manner." Mol. Cell. Biol. **23**(14): 4870-4881.

<http://mcb.asm.org/cgi/content/abstract/23/14/4870>

S100B is a Ca²⁺-modulated protein of the EF-hand type with both intracellular and extracellular roles. S100B, which is most abundant in the brain, has been shown to exert trophic and toxic effects on neurons depending on the concentration attained in the extracellular space. S100B is also found in normal serum, and its serum concentration increases in several nervous and nonnervous pathological conditions, suggesting that S100B-expressing cells outside the brain might release the protein and S100B might exert effects on nonnervous cells. We show here that at picomolar to nanomolar levels, S100B inhibits myogenic differentiation of rat L6 myoblasts via inactivation of p38 kinase with resulting decrease in the expression of the myogenic differentiation markers, myogenin, muscle creatine kinase, and myosin heavy chain, and reduction of myotube formation. Although myoblasts express the multiligand receptor RAGE, which has been shown to transduce S100B effects on neurons, S100B produces identical effects on myoblasts overexpressing either full-length RAGE or RAGE lacking the transducing domain. This suggests that S100B affects myoblasts by interacting with another receptor and that RAGE is not the only receptor for S100B. Our data suggest that S100B might participate in the regulation of muscle development and regeneration by inhibiting crucial steps of the myogenic program in a RAGE-independent manner.

Van Sloun, P. P. H., I. Varlet, et al. (2002). "Involvement of Mouse Rev3 in Tolerance of Endogenous and Exogenous DNA Damage." *Mol. Cell. Biol.* **22**(7): 2159-2169.

<http://mcb.asm.org/cgi/content/abstract/22/7/2159>

The Rev3 gene of *Saccharomyces cerevisiae* encodes the catalytic subunit of DNA polymerase {zeta} that is implicated in mutagenic translesion synthesis of damaged DNA. To investigate the function of its mouse homologue, we have generated mouse embryonic stem cells and mice carrying a targeted disruption of Rev3. Although some strain-dependent variation was observed, Rev3^{-/-} embryos died around midgestation, displaying retarded growth in the absence of consistent developmental abnormalities. Rev3^{-/-} cell lines could not be established, indicating a cell-autonomous requirement of Rev3 for long-term viability. Histochemical analysis of Rev3^{-/-} embryos did not reveal aberrant replication or cellular proliferation but demonstrated massive apoptosis in all embryonic lineages. Although increased levels of p53 are detected in Rev3^{-/-} embryos, the embryonic phenotype was not rescued by the absence of p53. A significant increase in double-stranded DNA breaks as well as chromatid and chromosome aberrations was observed in cells from Rev3^{-/-} embryos. The inner cell mass of cultured Rev3^{-/-} blastocysts dies of a delayed apoptotic response after exposure to a low dose of N-acetoxy-2-acetylaminofluorene. These combined data are compatible with a model in which, in the absence of polymerase {zeta}, double-stranded DNA breaks accumulate at sites of unreplicated DNA damage, eliciting a p53-independent apoptotic response. Together, these data are consistent with involvement of polymerase {zeta} in translesion synthesis of endogenously and exogenously induced DNA lesions.

Waggoner, S. A. and S. A. Liebhaber (2003). "Identification of mRNAs Associated with {alpha}CP2-Containing RNP Complexes." *Mol. Cell. Biol.* **23**(19): 7055-7067.

<http://mcb.asm.org/cgi/content/abstract/23/19/7055>

Posttranscriptional controls in higher eukaryotes are central to cell differentiation and developmental programs. These controls reflect sequence-specific interactions of mRNAs with one or more RNA binding proteins. The {alpha}-globin poly(C) binding proteins ({alpha}CPs) comprise a highly abundant subset of K homology (KH) domain RNA binding proteins and have a characteristic preference for binding single-stranded C-rich motifs. {alpha}CPs have been implicated in translation control and stabilization of multiple cellular and viral mRNAs. To explore

the full contribution of α CPs to cell function, we have identified a set of mRNAs that associate in vivo with the major α CP2 isoforms. One hundred sixty mRNA species were consistently identified in three independent analyses of α CP2-RNP complexes immunopurified from a human hematopoietic cell line (K562). These mRNAs could be grouped into subsets encoding cytoskeletal components, transcription factors, proto-oncogenes, and cell signaling factors. Two mRNAs were linked to ceroid lipofuscinosis, indicating a potential role for α CP2 in this infantile neurodegenerative disease. Surprisingly, α CP2 mRNA itself was represented in α CP2-RNP complexes, suggesting autoregulatory control of α CP2 expression. In vitro analyses of representative target mRNAs confirmed direct binding of α CP2 within their 3' untranslated regions. These data expand the list of mRNAs that associate with α CP2 in vivo and establish a foundation for modeling its role in coordinating pathways of posttranscriptional gene regulation.

Zhao, F., R. McCarrick-Walmsley, et al. (2003). "Inhibition of p300/CBP by Early B-Cell Factor." Mol. Cell. Biol. **23**(11): 3837-3846.

<http://mcb.asm.org/cgi/content/abstract/23/11/3837>

Early B-cell factor (EBF) is a DNA binding protein required for early B-cell development. It activates transcription of several B-cell-specific genes, including the λ 5 gene, which encodes a protein necessary for signaling by the pre-B-cell receptor. In an effort to understand the mechanism by which EBF activates transcription, we examined its interaction with the coactivator protein p300/CBP. We found that two domains of EBF each bind the histone acetyltransferase (HAT)/CH3 domain of p300/CBP both in vitro and in vivo. Surprisingly, transcriptional activation by EBF was not sensitive to E1A, a potent p300/CBP inhibitor. In fact, overexpressed EBF mimicked E1A by severely repressing the activity of several other transcription factors, including E47, a protein that acts cooperatively with EBF to promote transcription of the λ 5 gene. This broad inhibitory profile correlated with EBF's ability to repress the HAT activity of p300/CBP in vivo and in vitro. However, such a repressed complex is not likely to form at the λ 5 promoter in vivo since (i) EBF could not bind p300/CBP and DNA simultaneously and (ii) the cooperativity imparted by E47 was sensitive to E1A. Our data reveal an intriguing inhibitory property of EBF--a property shared only by E1A, Twist, Pu.1, and the Hox family of homeodomain proteins--and suggest that E47 and EBF play distinct roles during λ 5 promoter activation.

Zofall, M., J. Persinger, et al. (2004). "Functional Role of Extranucleosomal DNA and the Entry Site of the Nucleosome in Chromatin Remodeling by ISW2." Mol. Cell. Biol. **24**(22): 10047-10057.

<http://mcb.asm.org/cgi/content/abstract/24/22/10047>

A minimal amount of extranucleosomal DNA was required for nucleosome mobilization by ISW2 as shown by using a photochemical histone mapping approach to analyze nucleosome movement on a set of nucleosomes with varied lengths of extranucleosomal DNA. ISW2 was ineffective in repositioning or mobilizing nucleosomes with ≥ 20 bp of extranucleosomal DNA. In addition, ISW2 was able to slide nucleosomes to within only 10 to 13 bp of the edge of DNA fragments. The nucleosome mobilization was promoted by extranucleosomal single-stranded DNA with modest strand preference. Gaps (10 bp) just inside the nucleosome and in the extranucleosomal DNA showed that the transfer of torsional strain (twist) into the nucleosomal DNA region was not required for mobilizing nucleosomes. However, indications are that the extranucleosomal DNA immediately adjacent to the nucleosome has an important role in the initial stage of nucleosome movement by ISW2.

Ahmed, S. A., K. Snow-Bailey, et al. (2005). "Nine Novel Germline Gene Variants in the RET Proto-Oncogene Identified in Twelve Unrelated Cases." Mol. Diagn. 7(2): 283-288.

<http://jmd.amjpathol.org/cgi/content/abstract/7/2/283>

We report nine novel DNA alterations in the RET proto-oncogene in 12 unrelated cases identified by DNA sequencing of exons 10 and 11 of the gene. The novel variants K666E, IVS9-11G[-&gt]A, D631V in cis with H665Q, D631E (with C634Y), E623K (in trans with C618S), 616delGAG (in trans with C609Y), Y606C, C630R, and R635-T636insELCR;T636P were detected in patients with various clinical presentations ranging from thyroid goiter, medullary thyroid carcinoma, and pheochromocytoma to classic multiple endocrine neoplasia type 2A. When novel DNA alterations are found, extended family studies can be helpful in determining the clinical significance of such findings. Segregation within families suggests that K666E and T636insELCR;T636P are likely to be disease-causing mutations. However, the mechanism by which they affect the normal activity of the RET receptor is unclear. Absence of segregation with disease was observed for E623K and 616delGAG. For the remainder of the DNA alterations, family studies were not possible, and the clinical significance of these novel variants needs further assessment. Additional case reports, animal models, and/or functional studies are needed to determine the clinical significance of these newly identified variants.

Ahrens, K., R. Braylan, et al. (2002). "IgH PCR of Zinc Formalin-Fixed, Paraffin-Embedded Non-Lymphomatous Gastric Samples Produces Artifactual "Clonal" Bands Not Observed in Paired Tissues Unexposed to Zinc Formalin." Mol. Diagn. 4(3): 159-163.

<http://jmd.amjpathol.org/cgi/content/abstract/4/3/159>

Helicobacter pylori (HP) causes dense gastritis that can be difficult to distinguish morphologically from MALT-type lymphoma (ML). Immunoglobulin heavy chain (IgH) gene analysis by polymerase chain reaction (PCR) is often used to resolve diagnosis. However, monoclonal bands have been reported in nonmalignant cases of gastritis. Retrospectively, 16 gastric ML with both formalin-fixed, paraffin-embedded (FF-PE) and ethanol-fixed samples (EF), and 9 cases of FF-PE HP-gastritis were analyzed by IgH PCR to document the presence of non-reproducible bands in HP-gastritis, but not ML samples. In duplicate analyses, 12 of 16 ML yielded identical monoclonal bands in FF-PE and EF samples whereas 3 of 9 FF-PE gastritis cases yielded different-sized (ie, non-reproducible) "clonal" bands. Sequencing of two PCR products from a gastritis case confirmed IgH gene sequences. To investigate whether FF-PE had a direct effect on producing these non-reproducible bands, 7 gastrectomy samples were prospectively divided into EF and FF-PE halves for IgH PCR. All 7 samples demonstrated polyclonal smears in EF portions while 4 of 7 FF-PE portions yielded either multiple distinct bands or non-reproducible bands. In conclusion, IgH PCR of FF-PE tissue can create artifactual "clonal" bands, which are the appropriate product size, contain IgH sequences, and, if not performed in duplicate, may confuse interpretation of B-cell clonality.

Antonescu, C. R., S. J. Tschernyavsky, et al. (2002). "Molecular Diagnosis of Clear Cell Sarcoma: Detection of EWS-ATF1 and MITF-M Transcripts and Histopathological and Ultrastructural Analysis of 12 Cases." Mol. Diagn. **4**(1): 44-52.

<http://jmd.amjpathol.org/cgi/content/abstract/4/1/44>

Clear cell sarcoma (CCS), also known as melanoma of soft parts, is an uncommon deep soft tissue tumor presenting typically in the lower extremities of young adults. Previous cytogenetic studies have established the specificity of the recurrent t(12;22)(q13;q12), resulting in a EWS-ATF1 fusion, for CCS. The prevalence of the EWS-ATF1 fusion in CCS remains unclear, since most genetically confirmed CCS have been reported as isolated cytogenetic or molecular diagnostic case reports. We therefore studied histologically confirmed CCS from 12 patients for the presence of EWS-ATF1 by reverse-transcriptase polymerase chain reaction (RT-PCR), using RNA extracted from either frozen (four cases) or formalin-fixed paraffin-embedded (eight cases) material. All primary tumors were located in the deep soft tissues of the extremities. Histologically, 10 cases had a typical epithelioid nested appearance. Most or all cases showed immunostaining for HMB45 (12 of 12), S-100 protein (10 of 12), and MITF (12 of 12). Ultrastructural analysis showed melanosomes in six of seven cases. The presence of an EWS-ATF1 fusion transcript was identified by RT-PCR in 11 of 12 cases (91%), all of which showed the same fusion transcript structure, namely the previously described in-frame fusion of EWS exon 8 to ATF1 codon 65. RT-PCR analysis for the melanocyte-specific splice form of the MITF transcript was positive in all cases tested (4 of 4). These data confirm that EWS-ATF1 detection can be used as a highly sensitive diagnostic test for CCS and that CCS expresses the melanocyte-specific form of the MITF transcript, further supporting its genuine melanocytic differentiation.

Barrans, S. L., P. A. S. Evans, et al. (2003). "The Detection of t(14;18) in Archival Lymph Nodes: Development of a Fluorescence in Situ Hybridization (FISH)-Based Method and Evaluation by Comparison with Polymerase Chain Reaction." Mol. Diagn. **5**(3): 168-175.

<http://jmd.amjpathol.org/cgi/content/abstract/5/3/168>

Fluorescence in situ hybridization (FISH) has been used to demonstrate the t(14;18) in up to 100% of follicular lymphoma (FL) cases, however, there is little reproducible data using fixed tissue. The aim was therefore to develop a robust FISH method for the demonstration of translocations in archival tissue. The technique was evaluated by comparison with multiplex polymerase chain reaction (PCR), capable of detecting the majority of known breakpoints. Twenty-eight paired frozen and fixed cases of FL and 20 reactive controls were analyzed. The t(14;18) was detected in 23 of 28 cases using PCR on frozen material and 8 of 20 in paraffin. Using FISH, 24 of 26 frozen and 26 of 28 paraffin cases had a demonstrable translocation. All 20 reactive nodes were negative for the t(14;18) by PCR. Using FISH, one of the reactive cases had occasional cells with a translocation FISH pattern, demonstrable in frozen and paraffin samples. This is consistent with the presence of the t(14;18), which is well described in normal individuals. Both PCR and FISH are highly effective for t(14;18) analysis in unfixed tissue. When only paraffin blocks are available, FISH is the method of choice, and a result was achieved in 100% of cases. The method is applicable to the retrospective analysis of a range of translocations.

Baudhuin, L. M., M. Mai, et al. (2005). "Analysis of hMLH1 and hMSH2 Gene Dosage Alterations in Hereditary Nonpolyposis Colorectal Cancer Patients by Novel Methods." Mol. Diagn. **7**(2): 226-235.

<http://jmd.amjpathol.org/cgi/content/abstract/7/2/226>

A significant fraction of hereditary nonpolyposis colorectal cancer cases with defective mismatch repair (ie, Lynch syndrome) have large genomic deletions or duplications in the mismatch repair genes, hMLH1 and hMSH2, which can be challenging to detect by traditional methods. For this study, we developed and validated a novel Southern blot analysis method that allows for ascertainment of the extent of the dosage alterations on an exon-by-exon basis and compared this method to a second novel technique, multiplex ligation-dependent probe amplification (MLPA). From a total of 254 patients referred for Lynch syndrome testing, 20 of the 118 MLH1 cases and 42 of the 136 MSH2 cases had large genomic alterations, as detected by Southern blot. MLPA and Southern blot results were concordant with the exception of three major discrepancies: one because of a lack of MLPA probes for the region altered, another because of a point mutation near the MLPA probe ligation site, and another that was unexplained. Compared to Southern blot, MLPA has a shorter turn-around time, the analysis is less costly, less time-consuming, and less labor-intensive, and results are generally clear and unambiguous. However, concerns with MLPA include the presence of false-negatives and -positives because of positioning of probes and DNA variants near the probe ligation site. Overall, both Southern blot and MLPA provide important tools for the complete evaluation of patients with Lynch syndrome.

Carbone, A., A. Gloghini, et al. (2005). "Kaposi's Sarcoma-Associated Herpesvirus/Human Herpesvirus Type 8-Positive Solid Lymphomas: A Tissue-Based Variant of Primary Effusion Lymphoma." Mol. Diagn. 7(1): 17-27.

<http://jmd.amjpathol.org/cgi/content/abstract/7/1/17>

Kaposi's sarcoma-associated herpesvirus (KSHV), also termed human herpesvirus type 8, is consistently identified in Kaposi's sarcoma, primary effusion lymphoma (PEL), and multicentric Castleman's disease. Here we report four cases of KSHV-bearing solid lymphomas that occurred in AIDS patients (cases 1 to 3) and in a human immunodeficiency virus (HIV)-seronegative person (case 4). The patients presented extranodal masses in the abdomen (cases 1, 3, and 4) or skin (case 2), and nodal involvement, together with Kaposi's sarcoma (case 3). The gastrointestinal tract was involved in two patients (cases 1 and 3). The patients did not develop a lymphomatous effusion. KSHV was detected in the tumor cells of all cases by immunohistochemistry and by polymerase chain reaction. Epstein-Barr virus was detected in two of the HIV-related cases. All KSHV-positive solid lymphomas exhibited PEL-like cell morphology. To investigate the relationship of these disorders to PEL and to other AIDS-associated diffuse large cell lymphomas, KSHV-positive solid lymphomas were tested for the expression of a set of genes that were previously shown by gene profiling analysis to define PEL tumor cells. The results showed that expression of this set of genes in KSHV-positive lymphomas is similar to that of PEL but distinct from KSHV-negative AIDS-associated diffuse large cell lymphomas. Because pathobiological features of KSHV-positive solid lymphomas closely mimic those of PEL, our results suggest that KSHV-positive solid lymphomas should be considered as a tissue-based variant of classical PEL, irrespective of HIV status.

Dorschner, M. O., D. Barden, et al. (2002). "Diagnosis of Five Spinocerebellar Ataxia Disorders by Multiplex Amplification and Capillary Electrophoresis." Mol. Diagn. 4(2): 108-113.

<http://jmd.amjpathol.org/cgi/content/abstract/4/2/108>

The autosomal-dominant spinocerebellar ataxias (ADCA) are a heterogeneous group of neurodegenerative disorders with variable expression and phenotypic overlap. An accurate diagnosis relies on detection of a mutation in a specific causative gene, which is typically an abnormal number of CAG trinucleotide repeats. To streamline testing in a clinical setting, we converted our current panel of tests for the spinocerebellar ataxias (SCA) types SCA1, SCA2,

SCA3, SCA6, and SCA7 from five independent amplification reactions analyzed by polyacrylamide gel electrophoresis (PAGE) to a single multiplex amplification reaction analyzed by capillary electrophoresis (CE). Multiplex amplification was facilitated by the use of chimeric primers; different lengths and fluorochromes distinguished the amplicons. During CE with commercially available molecular weight standards, the SCA amplicons migrated faster than predicted, thereby underestimating their length compared to that determined previously by PAGE. This was observed to varying degrees for each of the five loci, with the greatest size differential occurring in amplicons with greater (CAG)_n. To determine accurate amplicon length, and therefore an accurate number of CAG repeats, a size correction formula was calculated for each locus. This multiplex semi-automated assay has been reliable during 1 year of use in a clinical setting during which 57 samples were tested and five positive samples were detected.

Hadd, A. G., W. Laosinchai-Wolf, et al. (2004). "Microsphere Bead Arrays and Sequence Validation of 5/7/9T Genotypes for Multiplex Screening of Cystic Fibrosis Polymorphisms." *Mol. Diagn.* **6**(4): 348-355.

<http://jmd.amjpathol.org/cgi/content/abstract/6/4/348>

The development of simple and rapid methods for the detection of the common genetic mutations associated with cystic fibrosis (CF) requires access to positive-control samples including the 5/7/9T variants of intron 8. We used PCR and a simple multiplex bead-array assay to identify 5/7/9T control samples from 29 commercially available DNA samples. Unpurified PCR products were directly hybridized to color-coded beads containing allele-specific capture probes for 5/7/9T detection. The performance of the assay was investigated using reverse-complement oligonucleotides, individual PCR products, and multiplex PCR products for 5/7/9T detection within a complex CFTR screening assay. Samples were genotyped by grouping the relative signal intensities from each capture probe. Of 29 commercially available DNA samples analyzed, 2 5T/7T, 2 5T/9T, 9 7T/9T, 11 7T/7T, and 5 9T/9T genotypes were identified. The genotype within each sample group was confirmed by DNA sequencing. The assay was compatible with the analysis of 10 to 1000 ng of genomic DNA isolated from whole blood and allowed for the separate identification of primary CFTR mutations from reflex variants. The correct identification of positive controls demonstrated the utility of a simple bead-array assay and provided accessible samples for assay optimization and for routine quality control in the clinical laboratory.

Hamajima, N., T. Saito, et al. (2002). "Competitive Amplification and Unspecific Amplification in Polymerase Chain Reaction with Confronting Two-Pair Primers." *Mol. Diagn.* **4**(2): 103-107.

<http://jmd.amjpathol.org/cgi/content/abstract/4/2/103>

Polymerase chain reaction with confronting two-pair primers (PCR-CTPP) is an inexpensive, time-saving genotyping method that is applicable for most single nucleotide polymorphisms. To date, we have applied PCR-CTPP successfully for the genotyping of more than 30 polymorphisms. This paper demonstrates the differences in DNA amplification among different annealing temperatures of PCR-CTPP with given melting temperatures for four primers. The NQO1 C609T (Pro187Ser) polymorphism was used as an example. Two sets of four primers were applied for PCR-CTPP; the first set with different melting temperatures (T_{ms}), and the second with similar T_{ms}. The comparisons with one-pair primer PCR (allele-specific PCR) revealed that PCR-CTPP amplified DNA more specifically than allele-specific PCR. The primers with different T_{ms} caused competitive DNA amplification for heterozygous genotype. Four primers with similar T_{ms} amplified both alleles unspecifically at a lower annealing temperature, while the same DNA samples were correctly genotyped under an optimal annealing temperature. These findings are unique for PCR-CTPP, and important characteristics when the primers and

annealing temperatures in PCR-CTPP are designed. The knowledge of these characteristics will extend the applicability of PCR-CTPP for polymorphism genotyping.

Jebbink, J., X. Bai, et al. (2003). "Development of Real-Time PCR Assays for the Quantitative Detection of Epstein-Barr Virus and Cytomegalovirus, Comparison of TaqMan Probes, and Molecular Beacons." Mol. Diagn. **5**(1): 15-20.

<http://jmd.amjpathol.org/cgi/content/abstract/5/1/15>

Human Epstein-Barr virus (EBV) and cytomegalovirus (CMV) can cause serious complications in immunocompromised patients. Rapid diagnosis of EBV and CMV infection is critical in the management of the disease so that anti-viral therapy can be started early. Here we describe the development of real-time PCR assays using TaqMan probes and molecular beacons and compare the performance of both assays with a well-established, validated, gel-based PCR method for the quantification of EBV and CMV in patients' samples. The TaqMan and molecular beacon assays were linear between 10 to 10⁷ viral genomes/reaction. Both assays generated calibration curves with strong correlation and low intra-assay and interassay variation. Results of EBV and CMV viral load determination inpatient samples obtained by the gel-based and real-time PCR were very similar. The real-time PCR assays showed increases in viral load before clinical measures of viral disease and decreases in viral load during anti-viral therapy in two of six pediatric patients. The data indicate that these TaqMan and molecular beacon approaches are accurate, rapid, and reliable assays for the diagnosis and monitoring of EBV and CMV infections in patients.

Koga, T., Y. Horio, et al. (2004). "Identification of MGB1 as a Marker in the Differential Diagnosis of Lung Tumors in Patients with a History of Breast Cancer by Analysis of Publicly Available SAGE Data." Mol. Diagn. **6**(2): 90-95.

<http://jmd.amjpathol.org/cgi/content/abstract/6/2/90>

The risk of developing second primary cancers is increased in patients with breast cancer. The lung is one of the major target organs, and therefore a differential diagnosis between primary and metastatic cancers is required for the treatment of lung tumors in patients with a history of breast cancer. However, biopsy specimens frequently result in small, fragmented tissues containing only a few, degenerated cancer cells. We attempted to find a useful marker for differential diagnosis, using the online SAGE database. We selected three molecules, small breast epithelial mucin (SBEM), prostate epithelium-specific Ets transcription factor (PDEF), and mammaglobin (MGB1), as potential markers for breast cancer. SBEM and PDEF proved of no use for practical differential diagnosis because they are expressed in the normal bronchus. In contrast, expression of MGB1 was detected in all 22 primary breast cancers, but not in 22 normal lung tissues. Furthermore, all 12 metastatic breast cancers examined demonstrated positive MGB1 transcripts, whereas one of 48 primary lung adenocarcinomas expressed MGB1. This suggests that MGB1 can serve as a differential molecular marker. In practice, prospective examination, using the nine cases with a history of breast cancer, confirmed the usefulness of MGB1 in differential diagnosis.

Mitas, M., L. Hoover, et al. (2003). "Lunx Is a Superior Molecular Marker for Detection of Non-Small Lung Cell Cancer in Peripheral Blood." Mol. Diagn. **5**(4): 237-242.

<http://jmd.amjpathol.org/cgi/content/abstract/5/4/237>

The clinical management of non-small cell lung cancer (NSCLC) would benefit greatly by a test that was able to detect small amounts of NSCLC in the peripheral blood. In this report, we used a novel strategy to enrich tumor cells from the peripheral blood of 24 stage I to IV NSCLC patients and determined expression levels for six cancer-associated genes (lunx, muc1, KS1/4, CEA, CK19, and PSE). Using thresholds established at three standard deviations above the mean observed in 15 normal controls, we observed that lunx (10 of 24, 42%), muc1 (5 of 24, 21%), and CK19 (5 of 24, 21%) were overexpressed in 14 of 24 (58%) peripheral blood samples obtained from NSCLC patients. Patients who overexpressed either KS1/4 (n = 2) or PSE (n = 1) also overexpressed either lunx or muc1. Of patients with presumed curable and resectable stage I to II disease (n = 7), at least one marker was overexpressed in three (43%) patients. In advanced stage III to IV patients (n = 17), at least one marker was overexpressed in 11 patients (65%). These results provide evidence that circulating tumor cells can be detected in NSCLC patients by a high throughput molecular technique. Further studies are needed to determine the clinical relevance of gene overexpression.

Murphy, K. M., T. Geiger, et al. (2003). "A Single Nucleotide Primer Extension Assay to Detect the APC I1307K Gene Variant." Mol. Diagn. **5**(4): 222-226.

<http://jmd.amjpathol.org/cgi/content/abstract/5/4/222>

Adenomatous polyposis coli (APC) is a tumor suppressor gene important in colorectal tumorigenesis. A genetic variant of APC, I1307K, results from a T-to-A transversion at nucleotide 3920 which converts the wild-type sequence to a homopolymer tract (A8). The I1307K alteration is not itself oncogenic, but creates a hypermutable region (A8) that is prone to frame-shift mutations. The APC I1307K variant occurs in approximately 6% of the Ashkenazi Jewish population and is reported to approximately double an individual's risk for colorectal cancer. Here we describe a single nucleotide primer extension assay for the detection of the APC I1307K mutation. Following PCR amplification, nucleotide 3920 of the APC gene is directly sequenced using single nucleotide primer extension technology. The assay is in a multiplex format allowing simultaneous forward and reverse sequencing of the I1307K variant, which provides an internal, independent confirmation of each testing result. The assay was validated against 60 samples previously characterized by an allele-specific oligonucleotide (ASO) hybridization assay, with 100% concordance of results. Compared to the ASO assay, this single nucleotide primer extension assay requires significantly less technical time to perform, and has a greatly increased throughput capacity. The single nucleotide extension assay provides a highly sensitive and specific assay to identify individuals with the APC I1307K gene variant who may benefit from increased colorectal screening.

Patnaik, M., J. S. Dlott, et al. (2004). "Detection of Genomic Polymorphisms Associated with Venous Thrombosis Using the Invader Biplex Assay." Mol. Diagn. **6**(2): 137-144.

<http://jmd.amjpathol.org/cgi/content/abstract/6/2/137>

A multi-site study to assess the accuracy and performance of the biplex Invader assay for genotyping five polymorphisms implicated in venous thrombosis was carried out in seven laboratories. Genotyping results obtained using the Invader biplex assay were compared to those obtained from a reference method, either allele-specific polymerase chain reaction (AS-PCR), restriction fragment length polymorphism (PCR-RFLP) or PCR-mass spectrometry. Results were compared for five loci associated with venous thrombosis: Factor V Leiden, Factor II (prothrombin) G20210A, methylenetetrahydrofolate reductase (MTHFR) C677T and A1298C, and plasminogen activator inhibitor (PAI-1) 4G/5G. Of a total of 1448 genotypes tested in this study, there were 22 samples that gave different results between the Invader biplex assay and the PCR-

based methods. On further testing, 21 were determined to be correctly genotyped by the Invader Assay and only a single discrepancy was resolved in favor of the PCR-based assays. The compiled results demonstrate that the Invader biplex assay provides results more than 99.9% concordant with standard PCR-based techniques and is a rapid and highly accurate alternative to target amplification-based methods.

Plumbley, J. A., H. Fan, et al. (2002). "Lymphoid Tissues from Patients with Infectious Mononucleosis Lack Monoclonal B and T Cells." Mol. Diagn. 4(1): 37-43.

<http://jmd.amjpathol.org/cgi/content/abstract/4/1/37>

In typical cases of infectious mononucleosis (IM), lymphoid tissue is rarely submitted for pathological examination. When lymphoid tissues from IM cases are examined, the histological appearance of IM may be difficult to distinguish from malignant lymphoma. The purpose of this study was to address the utility of clinical molecular assays for T and B cell clonality in distinguishing IM from lymphoid malignancy. DNA was recovered from paraffin-embedded archival lymphoid tissues of 18 cases of IM and 13 control cases representing other reactive lymphoid hyperplasias. T cell receptor {gamma} (TCR-{gamma}) and immunoglobulin heavy chain (IgH) gene rearrangements were assayed using our standard clinical polymerase chain reaction procedures targeting each of the four functional variable (V) families and the three joining (J) families of the TCR-{gamma} gene, and framework III of the IgH gene, respectively. In 17 of 18 cases of IM, no monoclonal T or B cell populations were detectable. One case, the only spleen specimen in the study, had an oligoclonal pattern of TCR-{gamma} rearrangements. The control cases representing other reactive hyperplasias also lacked monoclonality. The assays used were sensitive to clonal populations as small as 5% of cells. In this case series, no monoclonal lymphoid populations were identified in any case of IM. This finding suggests that molecular studies are useful in distinguishing IM from lymphoid neoplasms.

Sanchez-Vega, B., F. Vega, et al. (2002). "Quantification of bcl-2/JH Fusion Sequences and a Control Gene by Multiplex Real-Time PCR Coupled with Automated Amplicon Sizing by Capillary Electrophoresis." Mol. Diagn. 4(4): 223-229.

<http://jmd.amjpathol.org/cgi/content/abstract/4/4/223>

Follicular lymphoma is characterized by the presence of the t(14;18)(q32;q21) chromosomal translocation which juxtaposes the bcl-2 gene at 18q21 with the immunoglobulin heavy chain locus at 14q32. Quantification of t(14;18) carrying cells in FL patients can be achieved by real-time PCR, a highly sensitive technique for evaluating treatment efficacy and minimal residual disease. Despite the many advantages of real-time technology for this purpose, one disadvantage is that current real-time t(14;18) PCR assays amplify a control gene as a normalizer in a separate reaction. Since each PCR reaction has its own kinetics, separate PCR assays for target and control sequences can potentially result in inaccurate quantification of t(14;18)-positive cells. In addition, the real-time t(14;18) PCR assays do not determine the size of the amplified fusion sequence, which is helpful for excluding contamination and is commonly used to demonstrate clonal identity between pre- and post-treatment specimens from a patient. To address these limitations, we designed a multiplex real-time PCR protocol that allows amplification of control and target genes in the same reaction and precise size determination of bcl-2/JH fusion sequences by capillary electrophoresis. This multiplex PCR assay is equally sensitive to previous assays, allows more accurate quantification of bcl-2/JH fusion sequences, and is more convenient.

Schrijver, I., S. Ramalingam, et al. (2005). "Diagnostic Testing by CFTR Gene Mutation Analysis in a Large Group of Hispanics: Novel Mutations and Assessment of a Population-Specific Mutation Spectrum." Mol. Diagn. 7(2): 289-299.

<http://jmd.amjpathol.org/cgi/content/abstract/7/2/289>

Characterization of CFTR mutations in the U.S. Hispanic population is vital to early diagnosis, genetic counseling, patient-specific treatment, and the understanding of cystic fibrosis (CF) pathogenesis. The mutation spectrum in Hispanics, however, remains poorly defined. A group of 257 self-identified Hispanics with clinical manifestations consistent with CF were studied by temporal temperature gradient electrophoresis and/or DNA sequencing. A total of 183 mutations were identified, including 14 different amino acid-changing novel variants. A significant proportion (78/85) of the different mutations identified would not have been detected by the ACMG/ACOG-recommended 25-mutation screening panel. Over one third of the mutations (27/85) occurred with a relative frequency >1%, which illustrates that the identified mutations are not all rare. This is supported by a comparison with other large CFTR studies. These results underscore the disparity in mutation identification between Caucasians and Hispanics and show utility for comprehensive diagnostic CFTR mutation analysis in this population.

Shadrach, B., M. Commane, et al. (2004). "A Rare Mutation in the Primer Binding Region of the Amelogenin Gene Can Interfere with Gender Identification." Mol. Diagn. 6(4): 401-405.

<http://jmd.amjpathol.org/cgi/content/abstract/6/4/401>

PCR amplification of part of the X-Y homologous amelogenin gene with a single primer pair has been used as a sex identification test because it generates different length products from the X and Y chromosomes. Using a commercially available kit that contains amelogenin primers, we report a single phenotypically normal Caucasian male out of 327 males tested to date that failed to show an X chromosome-specific PCR product. Using alternative amelogenin primers external to but encompassing the initial amplicon, an X chromosome-specific product was seen. Sequence analysis of this X-specific PCR product revealed a C to G mutation at the most 3' base of the initial reverse amelogenin PCR primer. An alternative reverse PCR primer with this most 3' base deleted showed X- and Y-specific products from the case study male. Rare mutations that result in a failure to amplify sex chromosome-specific products can result in incorrect gender identification.

Taylor, M. L., D. Sehgal, et al. (2004). "Demonstration That Mast Cells, T Cells, and B Cells Bearing the Activating Kit Mutation D816V Occur in Clusters within the Marrow of Patients with Mastocytosis." Mol. Diagn. 6(4): 335-342.

<http://jmd.amjpathol.org/cgi/content/abstract/6/4/335>

Mastocytosis is characterized by focal heterotypic clusters of mast cells and lymphocytes in the bone marrow and by a somatically acquired activating Kit mutation, D816V. The relationship of the occurrence of this mutation to the heterotypic clusters of mast cells and lymphocytes in bone marrow is unknown. We hypothesized that these two unique features of mastocytosis were related. To explore this hypothesis, laser capture microdissected mast cells, B cells, and T cells, from both lesional and non-lesional areas of bone marrow biopsy tissues from patients with mastocytosis, were examined for the D816V mutation in their DNA, using HinfI restriction

digestion of nested PCR products amplified from extracts of dissected cells. The D816V mutation was detected in mast cells, B cells, and T cells from lesional but not non-lesional areas of bone marrow tissues. B cells obtained from lesional areas of tissue were also assessed for clonality and were found to at least represent an oligoclonal population. Thus, mast cells and lymphocytes within focal aggregates in the bone marrow of those with mastocytosis are more frequently positive for the codon 816 activating mutation. Further, the B cell population is oligoclonal, suggesting that clonal proliferation is unlikely to be the basis of clustering.

Uchiyama, M., C. Maesawa, et al. (2005). "Consensus JH Gene Probes with Conjugated 3'-Minor Groove Binder for Monitoring Minimal Residual Disease in Acute Lymphoblastic Leukemia." Mol. Diagn. 7(1): 121-126.

<http://jmd.amjpathol.org/cgi/content/abstract/7/1/121>

Several approaches for the detection of minimal residual disease (MRD) in childhood acute lymphoblastic leukemia (ALL) have shown the importance of determining the level of MRD precisely. In the present study, we tested a new real-time quantitative polymerase chain reaction (RQ-PCR) strategy with minor groove binder (MGB) technology for immunoglobulin heavy chain gene rearrangements by positioning a MGB probe at the germline JH segments and one of the primers at the downstream introns in combination with an allele-specific oligonucleotide (ASO) primer complementary to the VH-DH or DH-JH junctional region. A MGB probe forms extremely stable duplexes with single-stranded DNA targets, allowing the use of shorter probes for hybridization-based assays. Therefore, it shows positional flexibility. We have designed two novel consensus MGB JH germline probes for analyzing all of the germline rearrangements registered in the V BASE database, and demonstrated that the MRD was detectable with the probes in 17 cases of childhood ALL. The actual copy number for the targets and dynamic changes before and after treatment were almost identical between the JH MGB probe and conventional non-MGB probes in each patient. MGB technology will undoubtedly contribute to MRD-PCR studies of childhood ALL.

Wang, Z.-Y., Q. Zhang, et al. (2003). "Detection of Protein Tyrosine-Kinase (PTK) Gene Expression Pattern in Normal and Malignant T Lymphocytes by Combined PTK-Specific Polymerase Chain Reaction and Parallel Denaturing Gradient Gel Electrophoresis." Mol. Diagn. 5(2): 113-120.

<http://jmd.amjpathol.org/cgi/content/abstract/5/2/113>

Protein tyrosine kinases (PTKs) control key functions of normal and malignant cells. Comparison of PTK gene expression among various cell populations may be achieved by amplification of the PTK cDNAs using degenerate primers which recognize two relatively invariable regions within their catalytic domain. This approach produces a mixture of PTK cDNA fragments with identical or very similar lengths which are difficult to separate by standard gel electrophoresis. These mixed products are then analyzed in a random fashion which leads to redundant cloning of some and potential omission of other PTKs. By using parallel denaturing gradient gel electrophoresis (DGGE) we have been able to separate the amplified PTK cDNAs derived from the same T-lymphocyte population and compare their expression between various types of normal and malignant T lymphocytes. One such PTK is the type I receptor for insulin-like growth factor, which we found to be preferentially expressed by neoplastic T cells on the both mRNA and protein levels. The combination of PCR which uses PTK-specific primers and parallel DGGE of the amplified PTK cDNAs may prove useful in studying mechanisms of cell activation and malignant transformation and in identifying targets for therapies based on selective inhibition of oncogenic PTKs.

Apostolakis, E. M., R. Lanz, et al. (2004). "Pituitary Adenylate Cyclase-Activating Peptide: A Pivotal Modulator of Steroid-Induced Reproductive Behavior in Female Rodents." Mol. Endocrinol. **18**(1): 173-183.

<http://mend.endojournals.org/cgi/content/abstract/18/1/173>

Pituitary adenylate cyclase-activating polypeptide (PACAP) regulates the secretion of GnRH into the hypothalamic hypophyseal portal system and sensitizes the pituitary for release of hormones that trigger ovulation. Because reproductive behavior is synchronized with GnRH release, the present study was undertaken to determine whether PACAP in the ventromedial nucleus (VMN) plays a role in receptivity. To this end, we used rat and mouse reproductive behavioral models to determine the biological relationship between PACAP and steroid receptor function in females. We provide evidence for the requirement of PACAP in the VMN for progesterone (P)-dependent sexual behavior in estrogen (E)-primed females. We clarify the biological and molecular mechanisms of PACAP activity by showing 1) that inhibition of endogenous PACAP suppresses P receptor (PR)-dependent sexual behavior facilitated by the steroid P or D1-like agonist SKF38393 and 2) that PR, steroid receptor coactivators-1 and -2, and new protein synthesis are essential for ligand independent PACAP-facilitated behavior. These findings are consistent with convergence of PACAP-mediated cellular signals on PR for genomic activation and subsequent behavioral changes. Further, we show that steroids regulate both endogenous PACAP mRNA in the VMN and immunoreactive PACAP in the medial basal hypothalamus and cerebral spinal fluid for ligand-dependent, steroid receptor-dependent receptivity. The present findings delineate a novel, steroid-dependent mechanism within the female hypothalamus by which the neuropeptide PACAP acts as a feed-forward, paracrine, and/or autocrine factor for synchronization of behavior coordinate with hypothalamic control of ovulation.

Eijken, M., M. Hewison, et al. (2005). "11{beta}-Hydroxysteroid Dehydrogenase Expression and Glucocorticoid Synthesis Are Directed by a Molecular Switch during Osteoblast Differentiation." Mol. Endocrinol. **19**(3): 621-631.

<http://mend.endojournals.org/cgi/content/abstract/19/3/621>

11{beta}-Hydroxysteroid dehydrogenase type 1 (11{beta}-HSD1) plays an important role in the prereceptor regulation of corticosteroids by locally converting cortisone into active cortisol. To investigate the impact of this mechanism on osteoblast development, we have characterized 11{beta}-HSD1 activity and regulation in a differentiating human osteoblast cell line (SV-HFO). Continuous treatment with the synthetic glucocorticoid dexamethasone induces differentiation of SV-HFO cells during 21 d of culture. Using this cell system, we showed an inverse relationship between 11{beta}-HSD1 activity and osteoblast differentiation. 11{beta}-HSD1 mRNA expression and activity were low and constant in differentiating osteoblasts. However, in the absence of differentiation (no dexamethasone), 11{beta}-HSD1 mRNA and activity increased strongly from d 12 of culture onward, with a peak around d 19. Promoter reporter studies provided evidence that specific regions of the 11{beta}-HSD1 gene are involved in this differentiation controlled regulation of the enzyme. Functional implication of these changes in 11{beta}-HSD1 is shown by the induction of osteoblast differentiation in the presence of cortisone. The current study

demonstrates the presence of an intrinsic differentiation-driven molecular switch that controls expression and activity of 11 β -HSD1 and thereby cortisol production by human osteoblasts. This efficient mechanism by which osteoblasts generate cortisol in an autocrine fashion to ensure proper differentiation will help to understand the complex effects of cortisol on bone metabolism.

Hewetson, A., E. C. Hendrix, et al. (2002). "Identification of the RUSH Consensus-Binding Site by Cyclic Amplification and Selection of Targets: Demonstration that RUSH Mediates the Ability of Prolactin to Augment Progesterone-Dependent Gene Expression." *Mol. Endocrinol.* **16**(9): 2101-2112.

<http://mend.endojournals.org/cgi/content/abstract/16/9/2101>

RUSH-1 α / β transcription factors were cloned by recognition site screening with an 85-bp region (-170/-85) of the rabbit uteroglobin gene. Deletion analysis showed this region was essential to prolactin (PRL) action, but conclusions were limited by the complexity of the large deletion. Cyclic amplification and selection of targets (CASTing) was used to identify the RUSH-binding site (-126/-121). Endometrial nuclear proteins were incubated with a pool of degenerate oligonucleotides and immunoprecipitated with RUSH-1 α / β antibodies. Bound DNA was amplified by PCR. The consensus motif (MCWTDK) was identified after five rounds of CASTing, authenticated by CASTing with RUSH-1 α -specific antibodies and recombinant protein, and refined with EMSA. Dissociation rate constants (K_d = 0.1-1.0 nM; r = 0.99) revealed high-affinity binding. Chromatin immunoprecipitation confirmed *in vivo* binding of RUSH to the transcriptionally active uteroglobin promoter. CASTing also revealed RUSH-GATA transcription factor interactions. Endometrial GATA-4 expression is progesterone dependent (Northern analysis) and preferentially localized in the epithelium (in situ hybridization). Although physically affiliated with RUSH, uterine forms of GATA-4 were not required for RUSH-DNA binding. Site-directed mutagenesis and transient transfection assays showed the RUSH motif mediates the ability of PRL to augment progesterone-dependent uteroglobin transcription. RUSH is central to the mechanism whereby PRL augments progesterone-dependent gene transcription.

Hewitt, S. C., B. J. Deroo, et al. (2003). "Estrogen Receptor-Dependent Genomic Responses in the Uterus Mirror the Biphasic Physiological Response to Estrogen." *Mol. Endocrinol.* **17**(10): 2070-2083.

<http://mend.endojournals.org/cgi/content/abstract/17/10/2070>

The physiological responses of the rodent uterus to acute estrogen (E) dosing can be divided into early and late events. Examples of early responses include increased RNA transcription, hyperemia, and water imbibition 2 and 6 h following E administration respectively, whereas later responses include cycles of DNA synthesis and mitosis of epithelial cells beginning 10 and 16 h after E. The development of estrogen receptor (ER) knockout (ERKO) mice, combined with microarray technology, has allowed us to design a genomic approach to study the acute response of the rodent reproductive tract to E. To determine whether early and late biological responses are correlated with altered regulation of a single set of genes or distinct sets of genes characteristic of early and late responses, uterine RNA was obtained from ovariectomized mice that were treated with vehicle or with estradiol for 2 h (early) or 24 h (late). Samples were also prepared from identically treated mice that lacked either ER α (α ERKO) or ER β (β ERKO) to address the relative contributions of the ERs in the uterine responses. Microarray analysis of the relative expression of 8700 mouse cDNAs indicated distinct clusters of genes that were regulated both positively and negatively by E in the early or late phases as well as clusters of genes regulated at both times. Both early and late responses by the β ERKO samples were indistinguishable from those of WT samples, whereas the α ERKO showed little change in gene expression in response to E, indicating the predominant role for ER α in

the genomic response. Further studies indicated that the genomic responses in samples from intermediate time points (6 h, 12 h) fall within the early or late clusters, rather than showing unique clusters regulated in the intermediary period. The use of this genomic approach has illustrated how physiological responses are reflected in genomic patterns. Furthermore, the identification of functional gene families that are regulated by E in the uterus combined with the utilization of genetically altered experimental animal models can help to uncover and define novel mechanisms of E action.

Hwang, E. S., D. W. Kim, et al. (2004). "Regulation of Signal Transducer and Activator of Transcription 1 (STAT1) and STAT1-Dependent Genes by RET/PTC (Rearranged in Transformation/Papillary Thyroid Carcinoma) Oncogenic Tyrosine Kinases." *Mol. Endocrinol.* **18**(11): 2672-2684.

<http://mend.endojournals.org/cgi/content/abstract/18/11/2672>

Chimeric RET/PTC (rearranged in transformation/papillary thyroid carcinoma) oncoproteins are constitutively active tyrosine kinases found in thyroid papillary carcinoma and nonneoplastic Hashimoto's thyroiditis. Although several proteins have been identified to be substrates of RET/PTC kinases, the pathogenic roles played by RET/PTC in malignant and benign thyroid diseases and the molecular mechanisms that are involved are not fully understood. We found that RET/PTC expression phosphorylates the Y701 residue of STAT1, a type II interferon (IFN)-responsive protein. RET/PTC-mediated signal transducer and activator of transcription 1 (STAT1) phosphorylation requires RET/PTC kinase activity to be intact but other tyrosine kinases, such as Janus kinases or c-Src, are not involved. RET/PTC-induced STAT1 transcriptional activation was not inhibited by suppressor of cytokine signaling-1 or -3, or protein inhibitors of activated STAT3 [(protein inhibitor of activated STAT (PIAS3)], but PIAS1 strongly repressed the RET/PTC-induced transcriptional activity of STAT1. RET/PTC-induced STAT1 activation caused IFN regulatory factor-1 expression. We found that STAT1 and IFN regulatory factor-1 cooperated to significantly increase transcription from type IV IFN- γ -responsive promoters of class II transactivator genes. Significantly, cells stably expressing RET/PTC expressed class II transactivator and showed enhanced de novo membrane expression of major histocompatibility complex (MHC) class II proteins. Furthermore, RET/PTC1-bearing papillary thyroid carcinoma cells strongly expressed MHC class II (human leukocyte-associated antigen-DR α) genes, whereas the surrounding normal tissues did not. Thus, RET/PTC is able to phosphorylate and activate STAT1. This may lead to enhanced MHC class II expression, which may explain why the tissues surrounding RET/PTC-positive cancers are infiltrated with lymphocytes. Such immune response-promoting activity of RET/PTC may also relate to the development of Hashimoto's thyroiditis.

Ishii, S., M. Yamada, et al. (2004). "Aberrant Dynamics of Histone Deacetylation at the Thyrotropin-Releasing Hormone Gene in Resistance to Thyroid Hormone." *Mol. Endocrinol.* **18**(7): 1708-1720.

<http://mend.endojournals.org/cgi/content/abstract/18/7/1708>

Histone acetylation status influences transcriptional activity, and the mechanism of negative gene regulation by thyroid hormone remains unclear, although its impairment by a mutant thyroid hormone receptor (TR) is critical for resistance to thyroid hormone (RTH). We found a novel RTH mutant, F455S, that exhibited impaired repression of the TRH gene and had a strong dominant-negative effect on the gene. F455S strongly interacted with nuclear receptor corepressor (NCoR) and was hard to dissociate from it. To analyze the dynamics of histone acetylation status in vivo, we established cell lines stably expressing the TRH promoter and wild-type or F455S TR. Treatment with a histone deacetylase (HDAC) inhibitor completely abolished the repression of the

gene by T3. The histones H3 and H4 at the TRH promoter were acetylated, and addition of T3 caused recruitment of HDACs 2 and 3 within 15 min, resulting in a transient deacetylation of the histone tails. TR and NCoR were located on the promoter, and T3 caused NCoR dissociation and steroid receptor coactivator-1 recruitment. In the presence of F455S, the histones were hyperacetylated, and HDAC recruitment and histone deacetylation were significantly impaired. This is the first report demonstrating the direct involvement of aberrant dynamics of chromatin modification in RTH.

Jansen, E., J. S. E. Laven, et al. (2004). "Abnormal Gene Expression Profiles in Human Ovaries from Polycystic Ovary Syndrome Patients." Mol. Endocrinol. **18**(12): 3050-3063.

<http://mend.endojournals.org/cgi/content/abstract/18/12/3050>

Polycystic ovary syndrome (PCOS) represents the most common cause of anovulatory infertility and affects 5-10% of women of reproductive age. The etiology of PCOS is still unknown. The current study is the first to describe consistent differences in gene expression profiles in human ovaries comparing PCOS patients vs. healthy normoovulatory individuals. The microarray analysis of PCOS vs. normal ovaries identifies dysregulated expression of genes encoding components of several biological pathways or systems such as Wnt signaling, extracellular matrix components, and immunological factors. Resulting data may provide novel clues for ovarian dysfunction in PCOS. Intriguingly, the gene expression profiles of ovaries from (long-term) androgen-treated female-to-male transsexuals (TSX) show considerable overlap with PCOS. This observation provides supportive evidence that androgens play a key role in the pathogenesis of PCOS. Presented data may contribute to a better understanding of dysregulated pathways in PCOS, which might ultimately reveal novel leads for therapeutic intervention.

Oksche, A., G. Leder, et al. (2002). "Variant Amino Acids in the Extracellular Loops of Murine and Human Vasopressin V2 Receptors Account for Differences in Cell Surface Expression and Ligand Affinity." Mol. Endocrinol. **16**(4): 799-813.

<http://mend.endojournals.org/cgi/content/abstract/16/4/799>

Cloning and sequencing of the murine chromosomal region XB harboring the murine vasopressin V2 receptor (mV2R) gene and comparison with the orthologous human Xq28 region harboring the human vasopressin V2 receptor (hV2R) revealed conservation of the genomic organization and a high degree of sequence identity in the V2R coding regions. Despite an identity of 87% of the amino acid sequences, both receptors show marked functional differences upon stable expression in Chinese hamster ovary cells: the mV2R displayed a 5-fold higher affinity for [3H]AVP than the human ortholog; similar differences were found for the AVP-mediated activation of adenylyl cyclase. Saturation binding experiments with transiently transfected intact COS.M6 cells showed that the mV2R was 3- to 5-fold less abundantly expressed at the cell surface than the hV2R. Laser scanning microscopy of fusion proteins consisting of the V2Rs and green fluorescent protein (GFP) (mV2R/GFP, hV2R/GFP) demonstrated that the hV2R/GFP was efficiently transported to the plasma membrane, whereas the mV2R/GFP was localized mainly within the endoplasmic reticulum. Chimeric hV2Rs, in which the first and/or second extracellular loop(s) were replaced by the corresponding loop(s) of the mV2R, revealed that the second extracellular loop accounts for the differences in ligand binding, but the first extracellular loop accounts for the reduced cell surface expression. The exchange of lysine 100 by aspartate in the first extracellular loop of hV2R was sufficient to reduce cell surface expression, which was accompanied by intracellular retention as observed in laser scanning microscopy analysis. Conversely, the exchange of aspartate 100 by lysine in the mV2R increased the cell surface expression and resulted in predominant plasma membrane localization. Thus, a single amino acid

difference in the first extracellular loop between mV2R and hV2R determines the efficiency of cell surface expression.

Ousova, O., V. Guyonnet-Duperat, et al. (2004). "Corticosteroid Binding Globulin: A New Target for Cortisol-Driven Obesity." Mol. Endocrinol. **18**(7): 1687-1696.

<http://mend.endojournals.org/cgi/content/abstract/18/7/1687>

We present data suggesting that corticosteroid-binding globulin (CBG) may be the causal gene of a previously identified quantitative trait locus (QTL) associated with cortisol levels, fat, and muscle content in a pig intercross. Because Cbg in human and mouse maps in the region orthologous to the pig region containing this QTL, we considered Cbg as an interesting positional candidate gene because CBG plays a major role in cortisol bioavailability. Firstly, we cloned pig Cbg from a bacterial artificial chromosome library and showed by fluorescent in situ hybridization and radiation hybrid mapping that it maps on 7q26 at the peak of the QTL interval. Secondly, we detected in a subset of the pig intercross progeny a highly significant genetic linkage between CBG plasma binding capacity values and the chromosome 7 markers flanking the cortisol-associated QTL. In this population, CBG capacity is correlated positively to fat and negatively to muscle content. Thirdly, CBG capacity was three times higher in Meishan compared with Large White parental breeds and a 7-fold difference was found in Cbg mRNA expression between the two breeds. Overall, the data accumulated in this study point to Cbg gene as a key regulator of cortisol levels and obesity susceptibility.

Pasquali, C., M.-L. Curchod, et al. (2003). "Identification of Protein Tyrosine Phosphatases with Specificity for the Ligand-Activated Growth Hormone Receptor." Mol. Endocrinol. **17**(11): 2228-2239.

<http://mend.endojournals.org/cgi/content/abstract/17/11/2228>

Protein tyrosine phosphatases (PTPs) play key roles in switching off tyrosine phosphorylation cascades, such as initiated by cytokine receptors. We have used substrate-trapping mutants of a large set of PTPs to identify members of the PTP family that have substrate specificity for the phosphorylated human GH receptor (GHR) intracellular domain. Among 31 PTPs tested, T cell (TC)-PTP, PTP- β , PTP1B, stomach cancer-associated PTP 1 (SAP-1), Pyst-2, Meg-2, and PTP-H1 showed specificity for phosphorylated GHR that had been produced by coexpression with a kinase in bacteria. We then used GH-induced, phosphorylated GH receptor, purified from overexpressing mammalian cells, in a Far Western-based approach to test whether these seven PTPs were also capable of recognizing ligand-induced, physiologically phosphorylated GHR. In this assay, only TC-PTP, PTP1B, PTP-H1, and SAP-1 interacted with the mature form of the phosphorylated GHR. In parallel, we show that these PTPs recognize very different subsets of the seven GHR tyrosines that are potentially phosphorylated. Finally, mRNA tissue distribution of these PTPs by RT-PCR analysis and coexpression of the wild-type PTPs to test their ability to dephosphorylate ligand-activated GHR suggest PTP-H1 and PTP1B as potential candidates involved in GHR signaling.

Pi, M., R. H. Oakley, et al. (2005). " β -Arrestin- and G Protein Receptor Kinase-Mediated Calcium-Sensing Receptor Desensitization." Mol. Endocrinol. **19**(4): 1078-1087.

<http://mend.endojournals.org/cgi/content/abstract/19/4/1078>

Extracellular calcium rapidly controls PTH secretion through binding to the G protein-coupled calcium-sensing receptor (CASR) expressed in parathyroid glands. Very little is known about the regulatory proteins involved in desensitization of CASR. G protein receptor kinases (GRK) and β -arrestins are important regulators of agonist-dependent desensitization of G protein-coupled receptors. In the present study, we investigated their role in mediating agonist-dependent desensitization of CASR. In heterologous cell culture models, we found that the transfection of GRK4 inhibits CASR signaling by enhancing receptor phosphorylation and β -arrestin translocation to the CASR. In contrast, we found that overexpression of GRK2 desensitizes CASR by classical mechanisms as well as through phosphorylation-independent mechanisms involving disruption of G α q signaling. In addition, we observed lower circulating PTH levels and an attenuated increase in serum PTH after hypocalcemic stimulation in β -arrestin2 null mice, suggesting a functional role of β -arrestin2-dependent desensitization pathways in regulating CASR function in vivo. We conclude that GRKs and β -arrestins play key roles in regulating CASR responsiveness in parathyroid glands.

Piekorz, R. P., S. Gingras, et al. (2005). "Regulation of Progesterone Levels during Pregnancy and Parturition by Signal Transducer and Activator of Transcription 5 and 20 α -Hydroxysteroid Dehydrogenase." *Mol. Endocrinol.* **19**(2): 431-440.

<http://mend.endojournals.org/cgi/content/abstract/19/2/431>

The two highly related signal transducers and activators of transcription (Stats), Stat5a and Stat5b, are major mediators of prolactin signaling in both the mammary gland and in the ovary. Deficiencies in Stat5b, or in both Stat5a and Stat5b, result in loss of pregnancy during midgestation and are correlated with an increase in ovarian 20 α -hydroxysteroid dehydrogenase (20 α -HSD) and a decrease in serum progesterone, which normally declines only immediately before parturition. To determine the relative contribution of 20 α -HSD to progesterone metabolism and Stat5 function during pregnancy and parturition, we created a 20 α -HSD-deficient strain of mice by gene disruption. Mice deficient for 20 α -HSD sustain high progesterone levels and display a delay in parturition of several days demonstrating that 20 α -HSD regulates parturition downstream of the prostaglandin F2 α receptor in an essential and nonredundant manner. Moreover, 20 α -HSD deficiency partially corrected the abortion of pregnancies associated with Stat5b deficiency, supporting the concept that prolactin activation of Stat5b is important in suppressing 20 α -HSD gene expression and thereby allowing the maintenance of progesterone levels that are required to sustain pregnancy.

Qin, J., D.-m. Gao, et al. (2004). "Prospero-Related Homeobox (Prox1) Is a Corepressor of Human Liver Receptor Homolog-1 and Suppresses the Transcription of the Cholesterol 7- α -Hydroxylase Gene." *Mol. Endocrinol.* **18**(10): 2424-2439.

<http://mend.endojournals.org/cgi/content/abstract/18/10/2424>

Cholesterol 7- α -hydroxylase (CYP7A1) catalyzes a rate-limiting step in bile acid synthesis in liver, and its gene transcription is under complex regulation by multiple nuclear receptors in response to bile acids, cholesterol derivatives, and hormones. The liver receptor homolog-1 (LRH-1), a member of the fushi tarazu factor 1 subfamily of nuclear receptors, has emerged as an essential regulator for the expression of cyp7a1. In this report, we demonstrate Prox1, a prospero-related homeobox transcription factor, identified through a yeast two-hybrid screening, can directly interact with human LRH-1 (hLRH-1) and suppresses hLRH-1-mediated transcriptional activation of human cyp7a1 gene. Biochemical analysis demonstrates that Prox1 interacts with both the ligand binding domain (LBD) and the DNA binding domain (DBD) of hLRH-1. An LRKLL motif in Prox1 is important for the interaction with the LBD but not the DBD of hLRH-1.

1. In hLRH-1 LBD, helices 2 and 10 are essential for Prox1 recruitment. The suppression by Prox1 on the transcriptional activity of hLRH-1 can be mediated through its interaction with the LBD or the DBD of hLRH-1. Gel shift assays reveal that Prox1 impairs the binding of hLRH-1 to the promoter of human cyp7a1 gene.

Sales, K. J., S. Maudsley, et al. (2004). "Elevated Prostaglandin EP2 Receptor in Endometrial Adenocarcinoma Cells Promotes Vascular Endothelial Growth Factor Expression via Cyclic 3',5'-Adenosine Monophosphate-Mediated Transactivation of the Epidermal Growth Factor Receptor and Extracellular Signal-Regulated Kinase 1/2 Signaling Pathways." *Mol. Endocrinol.* **18**(6): 1533-1545.

<http://mend.endojournals.org/cgi/content/abstract/18/6/1533>

Prostaglandin (PG) E2 E-series prostanoid-2 (EP2) receptor is elevated in numerous carcinomas including the endometrium and has been implicated in mediating the effects of PGE2 on vascular function. In this study, we investigated the intracellular signaling pathways that are activated by the EP2 receptor and their role in regulation of the expression of vascular endothelial growth factor in endometrial adenocarcinoma (Ishikawa) cells. Ishikawa cells were stably transfected with EP2 receptor cDNA in the sense or antisense directions. Treatment of Ishikawa cells with PGE2 rapidly induced transactivation of the epidermal growth factor receptor (EGFR) and activation of ERK1/2 via the EP2 receptor. Preincubation of cells with chemical inhibitors of protein kinase A, c-Src, and EGFR kinase abolished the EP2-induced activation of EGFR and ERK1/2. PGE2 signaling via the EP2 receptor also promoted the mRNA expression and secretion of vascular endothelial growth factor protein in Ishikawa cells. This effect was inhibited by preincubation with chemical inhibitors of EGFR kinase, ERK1/2 signaling, and small inhibitory RNA molecules targeted against the EGFR. Therefore, we have demonstrated that elevated EP2 receptor expression may facilitate the PGE2-induced release of proangiogenic factors in reproductive tumor cells via intracellular cAMP-mediated transactivation of the EGFR and ERK1/2 pathways.

Schmitt, J. F., D. S. Millar, et al. (2002). "Hypermethylation of the Inhibin {alpha}-Subunit Gene in Prostate Carcinoma." *Mol. Endocrinol.* **16**(2): 213-220.

<http://mend.endojournals.org/cgi/content/abstract/16/2/213>

Inhibin is composed of an {alpha}- and a {beta}-subunit. Transgenic studies assigned a tumor-suppressive role to the inhibin {alpha}-subunit, and in human prostate cancer inhibin {alpha}-subunit gene expression was down-regulated. This study examined the inhibin {alpha}-subunit gene promoter and gene locus to determine whether promoter hypermethylation or LOH occurred in DNA from prostate cancer. The 5'-untranslated region of the human inhibin {alpha}-subunit gene was sequenced and shown to be highly homologous to the bovine, rat, and mouse inhibin {alpha}-subunit promoter sequences. A 135-bp region of the human promoter sequence that contained a cluster of CpG sites was analyzed for hypermethylation. Significant ($P < 0.001$) hypermethylation of the inhibin {alpha}-subunit gene promoter occurred in DNA from Gleason pattern 3, 4, and 5 carcinomas compared with nonmalignant tissue samples. A subset of the carcinomas with a cribriform pattern were unmethylated. LOH at 2q32-36, the chromosomal region harboring the inhibin {alpha}-subunit gene, was observed in 42% of prostate carcinomas. These data provide the first demonstration that promoter hypermethylation and LOH are associated with the inhibin {alpha}-subunit gene and gene locus in prostate cancer.

Sciacchitano, S., A. Orecchio, et al. (2002). "Cloning of the Mouse Insulin Receptor Substrate-3 (mIRS-3) Promoter, and Its Regulation by p53." Mol. Endocrinol. **16**(7): 1577-1589.

<http://mend.endojournals.org/cgi/content/abstract/16/7/1577>

The insulin receptor substrate-3 (IRS-3) is a member of a family of intermediate adapter proteins that function as major intracellular targets for phosphorylation by the activated insulin and IGF-I receptors. Among the four IRS proteins identified so far, IRS-3 exhibits a rather peculiar expression pattern during both the embryonic development and adult life, suggesting a different mechanism of regulation of its expression. In this study, we cloned the 5' flanking region of the mIRS-3 gene and analyzed its promoter activity. The mIRS-3 promoter is inhibited by wild-type p53, and this effect is completely abolished by cotransfection of a dominant negative p53. Tumor-derived p53 mutants show variable, but lower suppressing capability than wt p53. In addition, treatment with doxorubicin inhibits endogenous expression of mIRS-3 mRNA in C2C12 and 3T3-L1 cells. The DNA region spanning from nucleotides -287 and -178 in the mIRS-3 promoter is responsible for a 32.2% reduction of the mouse double minute 2 (MDM2) promoter activity, suggesting its involvement in the p53-mediated inhibitory effect. In conclusion, our study demonstrates that the mIRS-3 promoter is regulated by p53 at the transcriptional level. The inhibition of mIRS-3 promoter by wild-type p53, and its de-repression by tumor-derived p53 mutants, appears to be similar to that previously reported for the IGF-I receptor promoter, suggesting a common role of these two genes in p53-mediated cell growth and differentiation.

Shiota, M., T. Tanihiro, et al. (2003). "Protein Tyrosine Phosphatase PTP20 Induces Actin Cytoskeleton Reorganization by Dephosphorylating p190 RhoGAP in Rat Ovarian Granulosa Cells Stimulated with Follicle-Stimulating Hormone." Mol. Endocrinol. **17**(4): 534-549.

<http://mend.endojournals.org/cgi/content/abstract/17/4/534>

We identified 25 protein tyrosine phosphatases (PTPs) expressed in rat ovarian granulosa cells. Of these PTPs, the expression levels of at least PTP20, PTP-MEG1, PTP{epsilon}M, and PTP{epsilon}C significantly changed during the estrous cycle. We examined the cellular functions of PTP20 in granulosa cells by expressing the wild type, a catalytically inactive CS mutant in which Cys229 of PTP20 was changed to Ser, or a substrate-trapping DA mutant in which Asp197 was mutated to Ala, using an adenovirus vector. Overexpression of the wild type, but not of the CS mutant, induced retraction of the cell body with the extension of long, dendritic-like processes after stimulation with FSH, a critical factor for the survival and differentiation of these cells. In addition, cell adhesion to the substratum decreased in an FSH-dependent manner. Inhibiting Rho GTPase activity with C3 botulinum toxin caused similar morphological changes. The FSH-enhanced phosphotyrosine (p-Tyr) level of p190 RhoGAP was selectively reduced by the overexpressed wild type, but not by mutated PTP20. Although p190 RhoGAP is tyrosine phosphorylated by c-Src via the tyrosine kinase Pyk2, wild-type PTP20 had little effect on p-Tyr418 of c-Src and no effect on p-Tyr402 of Pyk2, which are required for full c-Src activity and for interacting between Pyk2 and c-Src, respectively. The CS and DA mutants as well as the wild type reduced the formation of p190 RhoGAP-p120 RasGAP complexes. Confocal microscopy analysis revealed that PTP20 intracellularly colocalizes with p190 RhoGAP. These results demonstrate that PTP20 regulates the functions of granulosa cells in an FSH-dependent manner by dephosphorylating p190 RhoGAP and subsequently inducing reorganization of the actin cytoskeleton. Moreover, our data suggest that PTPs play significant roles in controlling the dynamics of ovarian functions.

U, H. S., W. Alilain, et al. (2002). "Fetal Brain Progenitor Cells Transdifferentiate to Fates Outside the Nervous System." Mol. Endocrinol. **16**(11): 2645-2656.

<http://mend.endojournals.org/cgi/content/abstract/16/11/2645>

Central nervous system stem cells give rise to neurons and glia when exposed to specific trophic factors. In our studies with rat fetal brain-derived stem cells (RSCs), we showed that they could be induced to express the developmentally regulated transcription factors and cell markers characteristic of cells derived from another germ layer, e.g. pituitary cells. Therefore, rat fetal brain-derived stem cells do not seem to be restricted to a defined developmental fate. They may retain pluripotentiality and can be redirected to develop into other cell types not found in the brain provided the correct set of stimuli is present. This multipotent developmental behavior also suggests that instructive signals are operative.

Mol. Hum. Reprod. (23)

Akbar, F., S. Heinonen, et al. (2005). "Haplotypic association of DDAH1 with susceptibility to pre-eclampsia." Mol. Hum. Reprod. **11**(1): 73-77.

<http://molehr.oupjournals.org/cgi/content/abstract/11/1/73>

Association between pre-eclampsia (PEE1) and the dimethylarginine dimethylaminohydrolase (DDAH) 1 and 2 genes, which play a role in the regulation of nitric oxide synthesis and release, was studied. In a case-control study design single nucleotide polymorphisms (SNPs) were determined at eight sites in the DDAH1 gene and at one site (Pro231Pro) in the DDAH2 gene from 132 women with pre-eclampsia and 112 healthy controls. Three SNPs in the DDAH1 gene were associated with pre-eclampsia, showing complete linkage disequilibrium with each other, but none of the associations in the allele or genotype data reached statistical significance in either of the genes after the correction for multiple testing. Haplotype frequencies were estimated using a population based on a maximum likelihood method (EM algorithm). Four common DDAH1 haplotypes were present and a significant association of haplotypes H2 and H3 with pre-eclampsia ($P=0.03$) was found. The risk of pre-eclampsia was greatest in individuals (odds ratio: 3.93; 95% confidence interval: 1.54-9.99) who had two copies of the high-risk haplotypes (H2 or H3). The observed haplotypic association provides the first evidence of the importance of DDAH1 polymorphisms in pre-eclampsia susceptibility.

Cauffman, G., H. Van de Velde, et al. (2005). "Oct-4 mRNA and protein expression during human preimplantation development." Mol. Hum. Reprod. **11**(3): 173-181.

<http://molehr.oupjournals.org/cgi/content/abstract/11/3/173>

The transcription factor OCT-4 is regarded as a critical factor in controlling mammalian early embryonic development because of its role in toti-/pluripotency. In human preimplantation embryos, OCT-4 studies are limited to RNA analysis of abnormally developing embryos. This study thoroughly investigated the expression pattern of OCT-4 throughout the human preimplantation development. Expression was examined by single-cell RT-PCR or indirect immunocytochemistry in 36 single oocytes of various maturity and 112 normally developing preimplantation embryos at the level of single blastomeres, morulas, blastocysts, or inner cell mass (ICM) and trophectoderm (TE) samples. Oocytes and cleavage stage embryos revealed a variable OCT-4 expression pattern, concomitant with a pure cytoplasmic localization of the

protein. During compaction, the variability in expression faded away indicating embryonic OCT-4 expression and the protein appeared in the nucleus implying biological activity. In blastocysts, OCT-4 transcripts and proteins were present in the ICM and the TE. At protein level, blastocysts displayed different spatial expression patterns within a cell for the splice variants of OCT-4, which may endow them with different functional properties. As OCT-4 transcripts were also found in various differentiated cells, the presence of OCT-4 transcripts or proteins may not be sufficient for identifying undifferentiated cell lines in humans. Further, we suggest to examine the localization of OCT-4 proteins within a cell rather than to look for the presence and/or amount of transcripts.

Dalrymple, A., D. M. Slater, et al. (2002). "Molecular identification and localization of Trp homologues, putative calcium channels, in pregnant human uterus." Mol. Hum. Reprod. **8**(10): 946-951.

<http://molehr.oupjournals.org/cgi/content/abstract/8/10/946>

The mechanisms underlying the switch from uterine quiescence to contractile activity in labour are not clearly understood. Increasing evidence suggests that pathways of myometrial calcium homeostasis, including store-operated calcium entry (SOCE), may play an important role. The molecular basis of the membrane-associated calcium channels contributing to SOCE in pregnant human myometrium is not known, but they are likely to be hetero- or homo-oligomeric assemblies of transient receptor potential channel (TrpC) proteins, encoded by the mammalian homologues of *Drosophila* Trp genes. This study has therefore determined Trp gene expression and also TrpC protein expression and localization in term pregnant human myometrial tissue and primary cultured human myometrial smooth muscle (HMSM) cells. RT-PCR amplified fragments of Trp1, Trp3, Trp4, Trp6 and Trp7. PCR products were 100% homologous to published human sequences. Western blot analysis detected TrpC1, TrpC3, TrpC4 and TrpC6 proteins, which were of expected size. Immunolocalization revealed TrpC1, TrpC3, TrpC4 and TrpC6 protein expression in myometrial tissue and HMSM cells. TrpC protein immunostaining in HMSM cells was distributed in a distinct reticular fashion. TrpC proteins may be candidate proteins forming SOCE channels in term pregnant human myometrium.

De Vos, A., K. Sermon, et al. (2003). "Preimplantation genetic diagnosis for Charcot-Marie-Tooth disease type 1A." Mol. Hum. Reprod. **9**(7): 429-435.

<http://molehr.oupjournals.org/cgi/content/abstract/9/7/429>

Charcot-Marie-Tooth (CMT) disease is the common name for a range of hereditary peripheral neuropathies. CMT1 is the most common form and is transmitted in an autosomal dominant manner. CMT1A maps to chromosome 17p11.2 and is caused, in the majority of cases, by a 1.5 Mb DNA duplication, that includes the peripheral myelin protein 22 (PMP) gene. This paper reports on preimplantation genetic diagnosis (PGD) for CMT1A in five couples. The CMT1A duplication was detected by fluorescent PCR analysis using polymorphic (CA)_n markers localized within the duplication. Single-cell PCR on blastomeres allowed genetic analysis of embryos obtained after ICSI. Only healthy unaffected embryos were transferred to the uterus. PCR experiments with single EBV-transformed lymphoblasts or with research blastomeres allowed the evaluation of amplification efficiencies, as well as contamination and allele drop-out (ADO) rates for each PCR protocol. Three simplex PCR protocols (using one primer pair) and two duplex PCR protocols (using two primer pairs) were developed for CMT1A. Additionally, a protocol using all three primer pairs in triplex was also established. Thirteen clinical ICSI-PGD cycles were performed for five couples (12 simplex PCR cycles and one duplex PCR cycle), resulting in seven embryo transfers. Three singleton pregnancies ensued in two couples and three healthy babies were delivered. This report describes different fluorescent PCR-based tests which allow efficient and accurate single-cell level detection of the CMT1A duplication. On the basis of the presence of

the healthy allele of the affected parent-to-be (and/or absence of the affected one), healthy embryos can be selected for transfer. The assays are suitable for PGD for other couples who present with the same CMT1A duplication [depending on their informativity for the (CA)_n markers available] as described here.

Driver, P. M., S. Rauz, et al. (2003). "Characterization of human trophoblast as a mineralocorticoid target tissue." Mol. Hum. Reprod. **9**(12): 793-798.

<http://molehr.oupjournals.org/cgi/content/abstract/9/12/793>

In mineralocorticoid target tissues, 11 β -hydroxysteroid dehydrogenase type 2 (11 β -HSD2) confers mineralocorticoid receptor selectivity by metabolizing hormonally active cortisol to inactive cortisone, allowing aldosterone access to the receptor. This enzyme is also expressed in high abundance in fetal tissues, particularly in placental trophoblast, where a role has been proposed in regulating fetal growth and development by protecting the fetus from maternal hypercortisolaemia and modulating local glucocorticoid receptor (GR), rather than mineralocorticoid receptor-mediated responses. As such the placenta has not been considered a mineralocorticoid target tissue. We have used conventional RT-PCR and real-time quantitative RT-PCR to demonstrate that primary cultures of term human cytotrophoblast express the mineralocorticoid-responsive genes Na/K-ATPase (α 1 and β 1 subunits), epithelial sodium channel (ENaC, α and γ subunits) and the serum and glucocorticoid-inducible kinase (SGK). SGK expression was found to be rapidly and strongly induced by corticosteroids (24- and 38-fold by 10⁻⁷ mol/l aldosterone and 10⁻⁷ mol/l dexamethasone respectively after 1 h). Dexamethasone-, but not aldosterone-stimulated SGK induction was inhibited by GR antagonist (RU38486), confirming the presence of a functional mineralocorticoid receptor and suggesting that placental trophoblast expresses a functional mineralocorticoid receptor, which is in part responsible for the corticosteroid regulation of SGK expression. Placental 11 β -HSD2 may protect the MR in a fashion analogous to classical mineralocorticoid tissues to modulate trophoblast sodium transport.

Fiorentino, F., A. Biricik, et al. (2004). "Development and clinical application of a strategy for preimplantation genetic diagnosis of single gene disorders combined with HLA matching." Mol. Hum. Reprod. **10**(6): 445-460.

<http://molehr.oupjournals.org/cgi/content/abstract/10/6/445>

Preimplantation HLA matching has recently emerged as a tool for couples desiring to conceive a potential donor progeny for transplantation in a sibling with a life-threatening disorder. In this paper we describe a strategy optimized for preimplantation genetic diagnosis (PGD) of haemoglobinopathies combined with HLA matching. This procedure involves a minisequencing-based genotyping of HLA regions A, B, C and DRB combined with mutation analysis of the gene regions involved by mutation. Analysis of at least eight polymorphic short tandem repeat (STR) markers scattered through the HLA complex has also been included to detect potential contamination and crossing-over occurrences between HLA genes. The above assay can also be used for preimplantation HLA matching as a primary indication. The strategy was clinically applied for HLA matching in 17 cycles (14 for β -thalassaemia, one for Wiscott-Aldrich syndrome and two for leukaemia). A reliable HLA genotype was achieved in 255/266 (95.9%) of the blastomeres. In total, 22 (14.8%) embryos were obtained that were HLA-matched with the affected siblings, 14 (9.4%) of which were unaffected and transferred back to the patients. Four clinical pregnancies were obtained, three of which (one twin, two singletons) are ongoing and were confirmed as healthy and HLA-identical with the affected children. Minisequencing-based HLA typing combined with HLA STR haplotyping has been shown to be a reliable strategy for

preimplantation HLA matching. The major advantage of this approach is that the validation of a single assay can be done once and then used for the majority of the patients, reducing notably time needed for preclinical set-up of each case.

Fiorentino, F., M. C. Magli, et al. (2003). "The minisequencing method: an alternative strategy for preimplantation genetic diagnosis of single gene disorders." Mol. Hum. Reprod. **9**(7): 399-410.

<http://molehr.oupjournals.org/cgi/content/abstract/9/7/399>

We have applied a new method of genetic analysis, called minisequencing', to preimplantation genetic diagnosis (PGD) of monogenic disorders from single cells. This method involves computer-assisted mutation analysis, which allows exact base identity determination and computer-assisted visualization of the specific mutation(s), and thus facilitates data interpretation and management. Sequencing of the entire PCR product is unnecessary, yet the same qualitative characteristics of sequence analysis are maintained. The main benefit of the minisequencing strategy is the use of a mutation analysis protocol based on a common procedure, irrespective of the mutations involved. To evaluate the reliability of this method for subsequent application to PGD, we analysed PCR products from 887 blastomeres including 55 PGD cases of different genetic diseases, such as cystic fibrosis, {beta}-thalassaemia, sickle cell anaemia, haemophilia A, retinoblastoma, and spinal muscular atrophy. Minisequencing was found to be a useful technique in PGD analysis, due to its elevated sensitivity, automation, and easy data interpretation. The method was also efficient, providing interpretable results in 96.5% (856/887) of the blastomeres tested. Fifteen clinical pregnancies resulted from these PGD cases; conventional prenatal diagnosis confirmed all the PGD results, and 10 healthy babies have already been born. Its applicability to PGD could be helpful, particularly in cases in which the mutation(s) involved are difficult to assess by restriction analysis or other commonly used methods.

Horcajadas, J. A., A. Riesewijk, et al. (2005). "Effect of controlled ovarian hyperstimulation in IVF on endometrial gene expression profiles." Mol. Hum. Reprod. **11**(3): 195-205.

<http://molehr.oupjournals.org/cgi/content/abstract/11/3/195>

Controlled ovarian hyperstimulation (COH) used in IVF produces lower implantation rates per embryo transferred compared to natural cycles utilized in ovum donation, suggesting a suboptimal endometrial development. Endometrial receptivity has recently been investigated in natural menstrual cycles with the aid of microarray technology. The aim of this study is to investigate the impact of COH using urinary gonadotrophins with a long protocol with GnRH agonists without progesterone supplementation (similar to the natural cycle) on endometrial gene expression profiles during the window of implantation by comparing the profiles at day hCG+7 of COH versus LH+7 of a previous natural cycle in the same women. For this purpose we have used microarray technology by Affymetrix (GeneChip HG_U133A), which allows more than 22 000 genes to be tested simultaneously. Results were validated by semi-quantitative PCR and quantitative PCR experiments. We found that more than 200 genes showed a differential expression of more than 3-fold when COH and normal cycles were compared at hCG+7 versus LH+7. We simultaneously re-analysed the LH+2 versus LH+7 endometrial gene expression profiles in previous natural cycles in the same subject using this specific GeneChip, the results obtained were consistent with our own published results. This is the first time that gene expression profiles of the endometrium during COH are reported. The large degree of gene expression disturbance is surprising and highlights the need for further efforts to optimize COH protocols.

Jaleel, M. A., A. C. Tsai, et al. (2004). "Stromal cell-derived factor-1 (SDF-1) signalling regulates human placental trophoblast cell survival." *Mol. Hum. Reprod.* **10**(12): 901-909.

<http://molehr.oupjournals.org/cgi/content/abstract/10/12/901>

Stromal cell-derived factor-1 (SDF-1 or CXCL12) is the physiologic ligand for the chemokine receptor CXCR4. CXCR4-mediated signalling regulates cell migration and apoptosis in certain haematopoietic and neuronal cells. Using gene profiling, we determined that CXCR4 is the only chemokine receptor for which mRNA expression is regulated during trophoblast differentiation in vitro. Based on the known effects of CXCR4 ligation, we hypothesized that CXCR4 activation may regulate placental trophoblast cell survival (i.e. protection from apoptosis), an important mechanism for the establishment and maintenance of the uteroplacental barrier. Human cytotrophoblasts (CTBs) were cultured in defined media and treated with graded doses of SDF-1 (10-100 ng/ml) or with an anti-CXCR4 neutralizing antibody. Exposure to anti-CXCR4 antibody reduced CTB cell numbers by 25-40%. Treatment with SDF-1 decreased the proportions of apoptotic terminal deoxynucleotidyl transferase-mediated dUTP-FITC nick-end labelling(+) cells (apoptotic index [AI] of 2.79{+/-}0.61% [control] versus 1.88{+/-}0.56% [SDF-1]; $P<0.05$) and caspase-activated cells (AI of 7.95{+/-}2.49% [control] versus 3.81{+/-}1.49% [SDF-1]; $P<0.05$). We determined that SDF-1 also activated the triple MAP Kinase isoforms ERK1/2 and p38 in trophoblasts. Immunocytochemistry confirmed SDF-1-induced nuclear translocation of phosphorylated ERK1/2. Blocking of ERK1/2 signalling with the specific inhibitor PD98059 reversed SDF-1-mediated inhibition of apoptosis (AI of 1.65{+/-}0.34 [SDF-1] versus 3.50{+/-}0.5 [SDF-1 + PD98059]; $P<0.05$), suggesting that SDF-1 acts through this pathway as a trophoblast survival factor. These results indicate that SDF-1/CXCR4 signalling stimulates anti-apoptotic pathways in cultured trophoblasts. This chemotactic ligand/receptor system may promote trophoblast survival during pregnancy. Alterations in SDF-1 and/or CXCR4 expression or function may be associated with specific pregnancy disorders.

Kurahashi, N., F. Sata, et al. (2005). "Maternal genetic polymorphisms in CYP1A1, GSTM1 and GSTT1 and the risk of hypospadias." *Mol. Hum. Reprod.* **11**(2): 93-98.

<http://molehr.oupjournals.org/cgi/content/abstract/11/2/93>

Hypospadias is one of the most common congenital anomalies. Increased exposure to environmental factors (endocrine-disrupting chemicals and smoking) or maternal endogenous estrogen may cause hypospadias because male sexual differentiation is dependent on normal androgen homeostasis. Moreover, interactions between genetic factors and cigarette smoking and other chemicals have been suggested. It has been demonstrated that the CYP1A1 metabolizes not only environmental chemicals but also estrogens, and glutathione-S-transferases (GSTs) are detoxification enzymes that protect cells from toxicants by conjugation with glutathione. In this study, to investigate the association of CYP1A1 (MspI), GSTM1 and GSTT1 polymorphisms with hypospadias, a case-control study of 31 case mothers who had boys with hypospadias and 64 control mothers was performed in Japan. These polymorphisms were investigated by PCR-based methods using DNA from peripheral lymphocytes. We found that the heterozygous CYP1A1 and heterozygous and homozygous CYP1A1 were less frequent in the case mothers than in the control mothers [adjusted odds ratio (OR)=0.17, 95% confidence interval (CI)=0.04-0.74, OR = 0.28, 95% CI = 0.08-0.97, respectively]. We found no effect of maternal smoking on the hypospadias risks among the gene polymorphisms. The results suggest that mothers with the CYP1A1 MspI variant allele may have a decreased risk for hypospadias.

Loudon, J. A. Z., S. R. Sooranna, et al. (2004). "Mechanical stretch of human uterine smooth muscle cells increases IL-8 mRNA expression and peptide synthesis." Mol. Hum. Reprod. **10**(12): 895-899.

<http://molehr.oupjournals.org/cgi/content/abstract/10/12/895>

Labour is associated with increased synthesis of interleukin-8 (IL-8) by the fetal membranes and myometrium, which leads to an inflammatory infiltrate. Stretch has been shown to increase the expression of contraction-associated proteins in animal models of labour and in human myocytes in vitro. In this study, we tested the hypothesis that mechanical stretch of human myometrial cells increases IL-8 messenger ribonucleic acid (mRNA) expression. We isolated myocytes from non-pregnant women undergoing hysterectomy and pregnant women undergoing Caesarean section before and after the onset of labour. Myocytes in culture were subjected to stretch of varying intensity (6-16%) and duration (1 or 6 h) using the Flexercell system. IL-8 mRNA expression was lowest in myocytes from pregnant women not in labour, intermediate in those from non-pregnant women and greatest in those from pregnant women in labour. Stretch increased IL-8 mRNA expression independent of reproductive state. The stretch-induced increase in IL-8 mRNA expression was associated with higher IL-8 levels in the culture supernatant and enhanced promoter activity. These data suggest that stretch contributes to the increase in myometrial IL-8 synthesis associated with the onset of labour in humans.

Lundwall, A., A. Giwercman, et al. (2003). "A frequent allele codes for a truncated variant of semenogelin I, the major protein component of human semen coagulum." Mol. Hum. Reprod. **9**(6): 345-350.

<http://molehr.oupjournals.org/cgi/content/abstract/9/6/345>

Human semen coagulum predominantly consists of high molecular mass complexes of the seminal vesicle secreted semenogelin I (SgI) and semenogelin II (SgII). Here we describe a previously unknown variant of the SgI gene that is present at an allele frequency of [~]3% in the Swedish population. It gives rise to a protein with a molecular mass of 43 kDa, SgI43, which compared with the 50 kDa variant, SgI50, is lacking a tandem repeat of 60 amino acid residues that was probably deleted by homologous recombination. In spite of the size difference, SgI43 has many properties in common with SgI50, such as a very high iso-electric point and susceptibility to proteolytic degradation by prostate-specific antigen. Heterozygous carriers of the SgI43 allele neither show impaired fertility nor do they significantly differ from individuals homozygous for SgI50 with respect to sperm parameters such as semen volume, sperm count and fraction of motile spermatozoa.

Makela, S., R. Eklund, et al. (2005). "Mutational analysis of the human SLC26A8 gene: exclusion as a candidate for male infertility due to primary spermatogenic failure." Mol. Hum. Reprod. **11**(2): 129-132.

<http://molehr.oupjournals.org/cgi/content/abstract/11/2/129>

SLC26A8 is an anion transporter that is solely expressed in the testes. It interacts with MgcRacGAP that shows strong structural similarity with the Drosophila protein RotundRacGAP, which is established to have an essential role for male fertility in the fruit fly. To explore whether the SLC26A8 gene has a role in human male infertility, we performed mutational analysis in the coding region of the SLC26A8 gene in 83 male infertility patients and two groups of controls using single-strand conformational polymorphism and direct sequencing methods. We found six novel coding sequence variations, of which five lead to amino acid substitutions. All variants were found with similar frequencies in both patients and controls, thus suggesting that none of them may be

causally associated with infertility. We conclude that the SLC26A8 mutations are not a common cause of male infertility.

Piyamongkol, W., M. G. Bermudez, et al. (2003). "Detailed investigation of factors influencing amplification efficiency and allele drop-out in single cell PCR: implications for preimplantation genetic diagnosis." Mol. Hum. Reprod. **9**(7): 411-420.

<http://molehr.oupjournals.org/cgi/content/abstract/9/7/411>

Preimplantation genetic diagnosis (PGD) of single gene disorders relies on PCR-based tests performed on single cells (polar bodies or blastomeres). Despite the use of increasingly robust protocols, allele drop-out (ADO; the failure to amplify one of the two alleles in a heterozygous cell) remains a significant problem for diagnosis using single cell PCR. In extreme cases ADO can affect >40% of amplifications and has already caused several PGD misdiagnoses. We suggest that an improved understanding of the origins of ADO will allow development of more reliable PCR assays. In this study we carefully varied reaction conditions in >3000 single cell amplifications, allowing factors influencing ADO rates to be identified. ADO was found to be affected by amplicon size, amount of DNA degradation, freezing and thawing, the PCR programme, and the number of cells simultaneously amplified. Factors found to have little or no effect on ADO were local DNA sequence, denaturing temperature (94 or 96{degrees}C) and cell type. Consideration of the causal factors identified during this study should permit the design of PGD protocols that experience little ADO, thus improving the accuracy of PGD for single gene disorders.

Ray, P. F., N. Frydman, et al. (2002). "Birth of healthy female twins after preimplantation genetic diagnosis of cystic fibrosis combined with gender determination." Mol. Hum. Reprod. **8**(7): 688-694.

<http://molehr.oupjournals.org/cgi/content/abstract/8/7/688>

Two healthy sisters with a familial history of mental retardation were referred to our centre for preimplantation genetic diagnosis (PGD). Their two brothers showed severe mental retardation. The molecular basis for their disorder could not be identified, but one of the sisters and the mother presented a highly skewed pattern of X-inactivation reinforcing the likelihood of an X-linked mode of inheritance. Both sisters requested PGD to avoid the abortion of potentially affected male fetuses. PGD for sex by fluorescent in-situ hybridization was carried out for the first sister and resulted in the birth of a female child. The second sister and her partner, whose niece had cystic fibrosis (CF), were tested for CF mutations, and were both found to be $\Delta F508$ heterozygous. We developed an efficient single cell PCR protocol for the simultaneous amplification of the CF ($\Delta F508$) locus as well as the X-linked amelogenin gene and its highly homologous pseudogene on the Y chromosome. Two PGD cycles were carried out to screen against male and $\Delta F508$ homozygous deleted embryos. In each case several embryos could be selected for transfer and the second cycle resulted in a twin pregnancy followed by the birth of two healthy female infants.

Sales, K. J., A. A. Katz, et al. (2002). "Seminal plasma activates cyclooxygenase-2 and prostaglandin E2 receptor expression and signalling in cervical adenocarcinoma cells." Mol. Hum. Reprod. **8**(12): 1065-1070.

<http://molehr.oupjournals.org/cgi/content/abstract/8/12/1065>

Enhanced cyclooxygenase (COX) expression and prostaglandin E2 (PGE2) synthesis are regarded as promoters of neoplastic cell proliferation and angiogenesis. Expression of COX-2 and synthesis of PGE2 are up-regulated in cervical carcinomas. In sexually active women, growth and invasiveness of neoplastic cervical epithelial cells may be also under the direct influence of PGE2 present in seminal plasma. The aims of this study were to investigate the effect of seminal plasma and PGE2 on the expression of COX-2 and expression and signalling of the PGE2 receptor subtypes (EP1-EP4) in HeLa (cervical adenocarcinoma) cells. Treatment of HeLa cells with seminal plasma or PGE2 resulted in up-regulation of COX-2 expression ($P < 0.05$). In addition, seminal plasma induced the mRNA expression of EP1, EP2 and EP4 receptors, whilst PGE2 treatment of HeLa cells induced the expression of the EP4 receptor ($P < 0.05$). This was coincident with a rapid accumulation of adenosine 3',5'-cyclic monophosphate (cAMP) in HeLa cells stimulated with seminal plasma or PGE2, which was greater in seminal plasma stimulated cells compared with PGE2 stimulated cells ($P < 0.05$). Subsequently, we investigated whether the effect of seminal plasma on cAMP signalling in HeLa cells was mediated via the cAMP-linked EP2/EP4 receptors. Stimulation of HeLa cells with seminal plasma or PGE2 resulted in an augmented cAMP accumulation in cells transfected with the EP2 or EP4 receptor cDNA compared with control transfected cells ($P < 0.05$). These data suggest that, in sexually active women, seminal plasma may play a role in modulating neoplastic cell function and cervical tumorigenesis.

Sata, F., H. Yamada, et al. (2003). "Glutathione S-transferase M1 and T1 polymorphisms and the risk of recurrent pregnancy loss." *Mol. Hum. Reprod.* **9**(3): 165-169.

<http://molehr.oupjournals.org/cgi/content/abstract/9/3/165>

The aetiology of recurrent pregnancy loss (RPL) remains unclear, but it may be related to a possible genetic predisposition together with involvement of environmental factors. We examined the relation between RPL and polymorphisms in two genes, glutathione S-transferases (GST) M1 and T1, which are involved in the metabolism of a wide range of environmental toxins and carcinogens. A case-control study of 115 cases with RPL and 160 controls was conducted. All cases and controls were women resident in Sapporo, Japan and the surrounding area. They were genotyped for polymorphisms of GSTM1 and GSTT1 using PCR-based methods. We found that 65.2% of the cases with RPL and 45.6% of the controls had the GSTM1 null genotype [odds ratio (OR) = 2.23, 95% confidence interval (CI) = 1.36-3.66]. On the other hand, 47.0% of the cases and 49.4% of the controls had the GSTT1 null genotype (OR = 0.95; 95% CI = 0.58-1.55). The results suggest that women with GSTM1 null polymorphism may therefore have an increased risk of RPL.

Sata, F., H. Yamada, et al. (2003). "A polymorphism in the CYP17 gene relates to the risk of recurrent pregnancy loss." *Mol. Hum. Reprod.* **9**(11): 725-728.

<http://molehr.oupjournals.org/cgi/content/abstract/9/11/725>

The CYP17 gene encodes the enzyme cytochrome P450c17{ α }, which mediates both 17{ α }-hydroxylase and 17,20-lyase activity in the steroid biosynthesis pathway. A T[-&gt]C polymorphism in the 5' promoter region of CYP17 has been described. To examine the association between recurrent pregnancy loss (RPL) and a polymorphism in CYP17, a case-control study of 117 cases with RPL and 164 controls was conducted. This polymorphism was investigated by PCR/restriction fragment length polymorphism using DNA from peripheral

lymphocytes. The T[→]C transition in the variant allele (A2) creates a new recognition site for the restriction enzyme MspA1, which permits designation of the wildtype allele (A1) and A2. Women with the A2 allele of CYP17 had an increased risk of RPL [A1/A1 genotype (reference); A1/A2 genotype: odds ratio (OR), 1.68; 95% confidence interval (CI), 0.94-3.01; A2/A2 genotype: OR, 2.37; 95% CI, 1.16-4.83; P trend, 0.016]. Additionally, there was a similar tendency for the increased risk of primary RPL [A1/A1 genotype (reference); A1/A2 genotype: OR, 2.14; 95% CI, 1.14-4.01; A2/A2 genotype: OR, 2.50; 95% CI, 1.16-5.41; P trend, 0.015]. These results suggest that possession of the A2 variant of CYP17 may predispose to an increased risk of RPL with a gene dosage effect.

Shahid, M., V. S. Dhillon, et al. (2004). "Two new novel point mutations localized upstream and downstream of the HMG box region of the SRY gene in three Indian 46,XY females with sex reversal and gonadal tumour formation." *Mol. Hum. Reprod.* **10**(7): 521-526.

<http://molehr.oupjournals.org/cgi/content/abstract/10/7/521>

The Y chromosome-specific gene SRY is one of the key genes involved in human sex determination. The SRY gene encodes a testis-specific transcription factor that plays a key role in sexual differentiation and development in males and is located on the distal region of the short arm of the Y chromosome. Mutations in SRY gene result in XY sex reversal and pure gonadal dysgenesis. SRY expression initiates a network of gene activity that transforms the undifferentiated gonad, genital ridge into testis. Mutations in the SRY gene have been considered to account for only 10-15% of 46,XY gonadal dysgenesis cases, whereas the majority of the remaining cases may have mutation(s) in the SRY regulatory elements or other genes involved in the sex differentiation pathway. Patients both with gonadal dysgenesis and Y-chromosome presence are at high risk of developing gonadoblastoma. Using PCR, single strand conformational polymorphism (SSCP) and automated DNA sequencing, we analysed the mutations in the SRY gene in three 46,XY sex reversal patients. Two patients demonstrated nucleotide substitution (A[→]G) within the open reading frame just outside and upstream of the conserved DNA-binding motif called the high-mobility group (HMG) box, replacing glutamine at codon 57 with arginine. Altered SSCP patterns were also observed in these patients. Histological examination of gonads in patient 1 revealed the formation of gonadoblastoma. Patient 3 demonstrated A[→]T substitution which replaces serine at codon 143 with cysteine, just outside but downstream of the HMG box. Results suggest the involvement of SRY gene in sex reversal which further supports the relationship between SRY alterations, gonadal dysgenesis and/or primary infertility.

Sun, W. S., J. Fujimoto, et al. (2003). "Clinical implications of coexpression of growth arrest-specific gene 6 and receptor tyrosine kinases Axl and Sky in human uterine leiomyoma." *Mol. Hum. Reprod.* **9**(11): 701-707.

<http://molehr.oupjournals.org/cgi/content/abstract/9/11/701>

The expression of Gas6, the protein product of the growth arrest-specific gene 6 (gas6), a member of the vitamin K-dependent protein family, and the receptor tyrosine kinases Axl and Sky and their mRNAs in uterine leiomyoma and normal uterine myometrium tissues were investigated by competitive RT-PCR-Southern blot analysis using recombinant RNA and immuno histochemical analysis respectively. There was no significant difference between the histoscores and levels of Sky mRNA in uterine leiomyoma and normal uterine myometrium, although the levels of Gas6 and Axl mRNAs in uterine leiomyoma were significantly higher than in normal uterine myometrium in each case. It is suggested that Gas6 and Axl signal transduction is aberrantly stimulated in uterine leiomyoma, possibly related to its growth.

Sun, W. S., R. Misao, et al. (2002). "Coexpression of growth arrest-specific gene 6 and receptor tyrosine kinases, Axl and Sky, in human uterine endometrium and ovarian endometriosis." Mol. Hum. Reprod. **8**(6): 552-558.

<http://molehr.oupjournals.org/cgi/content/abstract/8/6/552>

We demonstrated the expression of Gas6, the protein product of the growth arrest-specific gene 6 (gas6) and a member of the vitamin K-dependent protein family, and its receptor tyrosine kinases, Axl and Sky, in human uterine and ovarian endometriotic endometria using RT-PCR-Southern blot analysis and immunohistochemistry. Gas6, Axl and Sky mRNA were detected in all samples analysed. There was no significant difference between the levels of Sky mRNA in normal uterine and endometriotic endometria; however, the levels of Gas6 and Axl mRNA in endometriotic endometria were significantly higher than in normal endometria. These mRNA levels showed no significant alteration during the menstrual cycle. In the immunohistochemical study, Gas6, Axl and Sky were found in endometrial glandular cells and stromal cells in all samples analysed. This study demonstrates the coexpression of receptor tyrosine kinases and their ligand, Gas6, in normal uterine and ovarian endometriotic endometria, and the overexpression of Axl and Gas6 in endometriotic endometria. It is suggested that Gas6 and Axl signal transduction is aberrantly stimulated in endometriotic endometria, and is plausibly related to its growth potential.

Wieser, F., C. Schneeberger, et al. (2002). "Endometrial nuclear receptor co-factors SRC-1 and N-CoR are increased in human endometrium during menstruation." Mol. Hum. Reprod. **8**(7): 644-650.

<http://molehr.oupjournals.org/cgi/content/abstract/8/7/644>

Steroid hormone receptor co-factors are abundantly expressed in the uterus in order to modify steroid hormone receptor action, either leading to activation or repression of transcription in the endometrium. However, the role of co-factors in remodelling of the human endometrium has not been established. We therefore endeavoured to evaluate the presence of the co-activator SRC (steroid receptor co-activator)-1 and the co-repressors N-CoR (nuclear receptor co-repressor) and steroid co-repressor SMRT (silencing mediator of retinoid and thyroid) receptors in the human endometrium during the different phases of the menstrual cycle. By using a real-time RT-PCR assay, we showed that SRC-1, N-CoR and SMRT mRNA are expressed in human endometrium during all phases of the menstrual cycle, as well as in inactive endometrium. Moreover, endometrial expression of SRC-1 and N-CoR mRNA increased during menstruation when compared with the other phases of the menstrual cycle ($P < 0.001$). Immunohistochemistry demonstrated that SRC-1 and N-CoR stain positive in the glandular epithelium and stroma in menstrual phase endometrium. The staining was weak in proliferative and secretory endometrium and absent in inactive endometrium. Our results suggest that differential expression of endometrial steroid receptor co-factors probably play a role in the regulation of human endometrium remodelling.

Yamada, H., F. Sata, et al. (2004). "A polymorphism in the CYP17 gene and intrauterine fetal growth restriction." Mol. Hum. Reprod. **10**(1): 49-53.

<http://molehr.oupjournals.org/cgi/content/abstract/10/1/49>

Intrauterine fetal growth restriction is a multifactorial disorder, and its aetiology includes both

environmental and genetic components. We aimed to investigate whether maternal genetic polymorphisms of metabolic enzymes affects fetal growth and pregnancy duration. Genomic DNA was obtained from 134 women who experienced singleton deliveries beyond 24 weeks of gestation. Maternal age, birth weight, gestational age at birth and frequencies of fetal growth restriction, prematurity and pregnancy-induced hypertension were compared among genotypic subgroups of cytochrome P450 (CYP) and glutathione S-transferase (GST) genes. The polymorphisms of CYP1A1 (MspI), CYP17 (MspAI) and GSTP1 (BsmAI) genotypes, and the presence or absence of GSTM1 and GSTT1 genes were analysed by PCR-based methods. The frequency of fetal growth restriction (<10th percentile/<-1.5 SD; 22.7%/11.4%) in 44 women who were homozygous for the A1 allele (A1A1) of CYP17 was significantly higher than that (7.8%/2.2%) in 90 women who carried the A2 allele (A1A2/A2A2) of CYP17 ($P < 0.05$), with an odds ratio =3.41 (95% confidence interval = 1.18-9.84). The gestational age at birth (mean {+/-} SD, 37.5 {+/-} 3.1 weeks) in 67 women with GSTM1 null genotype was significantly lower than that (38.5 {+/-} 2.4 weeks) in 67 women who carried GSTM1 ($P < 0.05$). The polymorphism of CYP17 that encodes the cytochrome P450c17{alpha} enzyme might be associated with the pathophysiology underlying fetal growth restriction.

Davids, V., S. H. Kidson, et al. (2003). "Accurate molecular detection of melanoma nodal metastases: an assessment of multimarker assay specificity, sensitivity, and detection rate." Mol. Pathol. **56**(1): 43-51.

<http://mp.bmjournals.com/cgi/content/abstract/56/1/43>

Background: The application of lymphoscintigraphy followed by sentinel lymph node (SN) biopsy to patients with primary melanoma has revolutionised the ability to identify accurately, yet conservatively, those patients who harbour occult nodal metastases. The molecular detection of SN micrometastases facilitates the cost effective analysis of the entire SN using multiple markers. Currently, a lack of marker specificity is the main barrier preventing the molecular evaluation of SN tissue from becoming clinically applicable. **Aims:** To develop a reproducible multimarker reverse transcription-polymerase chain reaction (RT-PCR) assay, with the emphasis on achieving high specificity for the accurate detection of melanoma metastases in nodal tissue. **Methods:** Three pigment cell specific (PCS) markers--tyrosinase, Pmel-17, and MART-1--and one cancer testis antigen (CTA)--MAGE-3--were selected for use in a multimarker RT-PCR assay. The conditions for this assay were optimised. **Results:** High specificity was achievable for each marker by optimising the PCR cycle number such that unwanted transcripts (that is, illegitimate transcripts and/or specific transcripts from other low abundance nodal cell types) remained undetectable in appropriate controls (normal visceral nodes). Tyrosinase was 100% specific at 40 PCR cycles, MAGE-3 and MART-1 at 35 PCR cycles, and Pmel-17 at 30 PCR cycles. Tyrosinase proved to be the most sensitive marker, detecting 10 melanoma cells in 0.1 g of nodal tissue. **Conclusions:** Excellent reproducibility of the entire nodal processing and RT-PCR protocol for the detection of very low numbers of melanoma cells in nodal tissue was shown, although there is a risk of false positives using the PCS markers alone, because of an approximate 4-8.5% incidence rate of nodal nevi in melanoma draining SNs (these nevi being absent in all other normal nodes). MAGE-3 was shown to be the only marker that is not expressed by melanocytes. However, because not all melanomas express MAGE-3, it is recommended that more emphasis should be placed on the development of a panel of CTA markers to ensure a zero false positive rate and to provide optimum detection.

Jung, A., S. Ruckert, et al. (2002). "7-Deaza-2'-deoxyguanosine allows PCR and sequencing reactions from CpG islands." Mol. Pathol. **55**(1): 55-57.

<http://mp.bmjjournals.com/cgi/content/abstract/55/1/55>

CpG islands are GC rich sequences that are found in the promoters of many genes in higher eukaryotes. They contain a high frequency of CG dinucleotides, which are substrates for DNA methylases. Methylation leads to transcriptional silencing of promoters. Owing to their high GC content CpG islands exhibit strong base-base interactions, which lead to superstructures and consequently to regions with higher melting temperatures. Therefore, Taq polymerases (especially sequenases) fall off their templates, causing premature termination of the polymerase chain reaction (PCR) or sequencing reactions. The results from such reactions are thus insufficient for further analysis. Therefore, we have evaluated the use of 7-deaza-2'-deoxyguanosine for PCR amplification of the human p16INK4A promoter and sequencing of HUMARA exon 1 PCR products. Our results show that the addition of 7-deaza-2'-deoxyguanosine significantly improves results, particularly when small amounts of poor quality DNA are available as starting material.

Lenze, D., A. Greiner, et al. (2003). "Receptor revision of immunoglobulin heavy chain genes in human MALT lymphomas." Mol. Pathol. **56**(5): 249-255.

<http://mp.bmjjournals.com/cgi/content/abstract/56/5/249>

Background/Aims: Rearrangement of immunoglobulin gene segments, leading to B cells with functional receptors, is thought to be largely restricted to developing immature B cells in bone marrow. However, accumulating evidence suggests that mature B cells occasionally modify their antigen specificity by VH segment replacements during the germinal centre reaction to enhance antigen affinity, or to overcome self reactive antigen receptors. Although malignant B cells maintain the features of their normal counterparts in most instances, to date, such replacements have not been described for human B cell lymphomas. **Methods:** Rearranged immunoglobulin heavy chain genes from two extranodal marginal zone B cell lymphomas were amplified, cloned, and sequenced. Sequences with identical CDR3 regions were selected and aligned to each other and public databases. **Results:** VH replacements were seen in two extranodal marginal zone B cell lymphomas. In line with the hypothesis that in mature B cells these replacements are associated with active somatic hypermutation, in addition to VH replacement, different mutation patterns were seen in the revised VH portions. In the remaining common 3'-VH regions, these mutations could be used to establish a phylogenetic relation between the sequences, rendering the possibility of artefactual chimaeric polymerase chain reaction products very unlikely. **Conclusions:** These results support the view that VH replacements are a further mechanism for reshaping antigen affinity and specificity, and indicate that these receptor modifications are not restricted to normal and reactive germinal centre B cells, but may also occur in close association with the development of malignant B cell lymphomas.

Baudhuin, L. M., K. L. Cristina, et al. (2002). "Akt Activation Induced by Lysophosphatidic Acid and Sphingosine-1-phosphate Requires Both Mitogen-Activated Protein Kinase Kinase and p38 Mitogen-Activated Protein Kinase and Is Cell-Line Specific." Mol. Pharmacol. **62**(3): 660-671.

<http://molpharm.aspetjournals.org/cgi/content/abstract/62/3/660>

The signaling pathways that lysophosphatidic acid (LPA) and sphingosine-1-phosphate (S1P) use to activate Akt in ovarian cancer cells are investigated here. We show for the first time, with the use of both pharmacological and genetic inhibitors, that the kinase activity and S473 phosphorylation of Akt induced by LPA and S1P requires both mitogen-activated protein (MAP) kinase kinase (MEK) and p38 MAP kinase, and MEK is likely to be upstream of p38, in HEY ovarian cancer cells. The requirement for both MEK and p38 is cell type- and stimulus-specific. Among 12 cell lines that we tested, 11 respond to LPA and S1P and all of the responsive cell lines require p38 but only nine of them require MEK. Among different stimuli tested, platelet-derived growth factor stimulates S473 phosphorylation of Akt in a MEK- and p38-dependent manner. However, epidermal growth factor, thrombin, and endothelin-1-stimulated Akt S473 phosphorylation require p38 but not MEK. Insulin, on the other hand, stimulates Akt S473 phosphorylation independent of both MEK and p38 in HEY cells. T308 phosphorylation stimulated by LPA/S1P requires MEK but not p38 activation. MEK and p38 activation were sufficient for Akt S473 but not T308 phosphorylation in HEY cells. In contrast to S1P and PDGF, LPA requires Rho for Akt S473 phosphorylation, and Rho is upstream of phosphatidylinositol 3-kinase (PI3-K). LPA/S1P-induced Akt activation may be involved in cell survival, because LPA and S1P treatment in HEY ovarian cancer cells results in a decrease in paclitaxel-induced caspase-3 activity in a PI3-K/MEK/p38-dependent manner.

Boverhof, D. R., E. Tam, et al. (2004). "2,3,7,8-Tetrachlorodibenzo-p-dioxin Induces Suppressor of Cytokine Signaling 2 in Murine B Cells." Mol. Pharmacol. **66**(6): 1662-1670.

<http://molpharm.aspetjournals.org/cgi/content/abstract/66/6/1662>

The B cell, a major component of humoral immunity, is a sensitive target for the immunotoxic effects of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD), possibly by rendering cells less responsive to antigenic or mitogenic stimulation. Potential mechanisms of TCDD action on B cells were examined in murine B cell lymphoma cells (CH12.LX) treated with 3 nM TCDD or dimethyl sulfoxide vehicle using sequence-verified cDNA microarrays. One transcript that was significantly induced by TCDD was suppressor of cytokine signaling 2 (Socs2). Changes in Socs2 mRNA levels paralleled that of Cyp1a1 with a maximal 3-fold induction observed at 4 h, as determined by quantitative real-time polymerase chain reaction. Socs2 induction seems B cell-specific, because no induction was observed in TCDD-responsive mouse hepatoma cells or human breast cancer cells. TCDD-mediated induction of Socs2 mRNA was dose-dependent and exhibited the characteristic structure-activity relationships observed for the aryl hydrocarbon receptor (AhR) ligands 3,3',4,4',5-pentachlorobiphenyl (PCB-126), indolo[3,2-b]-carbazole, and {beta}-naphthoflavone. Experiments with cycloheximide and AhR-deficient B cells indicated that Socs2 mRNA induction is a primary effect that is AhR-dependent. Western blot analysis confirmed that Socs2 and Cyp1a1 protein levels were also induced in CH12.LX cells. Promoter analysis revealed the presence of four dioxin-response elements within 1000 base pairs upstream of the Socs2 transcriptional start site, and a reporter gene regulated by the Socs2 promoter was inducible by TCDD. Promoter activity was also dependent on a functional AhR signaling pathway. These results indicate that Socs2 is a primary TCDD-inducible gene that may represent a novel mechanism by which TCDD elicits its immunosuppressive effects.

Briz, O., R. I. R. Macias, et al. (2003). "Usefulness of Liposomes Loaded with Cytostatic Bile Acid

Derivatives to Circumvent Chemotherapy Resistance of Enterohepatic Tumors." Mol. Pharmacol. **63**(3): 742-750.

<http://molpharm.aspetjournals.org/cgi/content/abstract/63/3/742>

We have investigated the sensitivity of the cisplatin-resistant enterohepatic tumor cell lines LS174T/R (human colon adenocarcinoma), WIF-B9/R (rat hepatoma-human fibroblast hybrid), and Hepa 1-6/R (mouse hepatoma) to free and liposome-encapsulated cytostatic bile acid derivatives Bamet-R2 and bamet-UD2. Expression of resistance associated genes was measured by quantitative reverse transcription-polymerase chain reaction or Western blotting. Drug uptake was determined by atomic absorption spectrophotometry. In resistant cells, overexpression of MRP1 and MRP2 was accompanied by reduced accumulation of cisplatin. The expression of MDR1 and GST-P was only enhanced in LS 174T/R. A higher expression of p53 was seen in LS 174T/R and Hepa 1-6/R cell lines but not in WIF-B9/R cells. In wild-type counterparts, uptake and cytostatic ability of Bamets were markedly higher (UD2 > R2) than that of cisplatin. Both effects were further enhanced by liposome formulation. Bamets were able to overcome cisplatin resistance in all cell lines. Cisplatin prolonged the survival time of nude mice in whose livers a Hepa 1-6 tumor had been implanted, but failed to exert a beneficial effect when the tumor was Hepa 1-6/R. In both cases, tissue distribution of cisplatin was: kidney [IMG] liver > tumor. Survival was markedly longer in animals receiving Bamet-UD2, even if the implanted tumor was resistant. The accumulation of Bamet-UD2 in tissues was: liver > tumor > kidney. Liposome formulation further enhanced the beneficial properties of Bamet-UD2. Thus, the amount of drug in the tumor was increased and that in liver and kidney was reduced (tumor > liver > kidney), and life span was prolonged. In conclusion, liposomal Bamet-UD2 may be a useful tool to circumvent resistance to chemotherapy, particularly in tumors of the enterohepatic circuit.

Cagetti, E., J. Liang, et al. (2003). "Withdrawal from Chronic Intermittent Ethanol Treatment Changes Subunit Composition, Reduces Synaptic Function, and Decreases Behavioral Responses to Positive Allosteric Modulators of GABAA Receptors." Mol. Pharmacol. **63**(1): 53-64.

<http://molpharm.aspetjournals.org/cgi/content/abstract/63/1/53>

One of the pharmacological targets of ethanol is the GABAA receptor (GABAR), whose function and expression are altered after chronic administration of ethanol. The details of the changes differ between experimental models. In the chronic intermittent ethanol (CIE) model for alcohol dependence, rats are exposed to intermittent episodes of intoxicating ethanol and withdrawal, leading to a kindling-like state of behavioral excitability. This is accompanied by presumably causal changes in GABAR expression and physiology. The present study investigates further the effect of CIE on GABAR function and expression. CIE is validated as a model for human alcohol withdrawal syndrome (AWS) by demonstrating increased level of anxiety; diazepam improved performance in the test. In addition, CIE rats showed remarkably reduced hypnotic response to a benzodiazepine and a steroid anesthetic, reduced sensitivity to a barbiturate, but not propofol. Immunoblotting revealed decrease in [alpha]1 and [delta] expression and increase in [gamma]2 and [alpha]4 subunits in hippocampus of CIE rats, confirmed by an increase in diazepam-insensitive binding for ethyl-8-azido-5,6-dihydro-5-methyl-6-oxo-4H-imidazo(1,5-[alpha])(1,4)benzodiazepine-3-carboxylate (Ro15-4513). Elevated mRNA levels were shown for the [gamma]2S and [gamma]1 subunits. Recordings in hippocampal slices from CIE rats revealed that the decay time of GABAR-mediated miniature inhibitory postsynaptic currents (mIPSCs) in CA1 pyramidal cells was decreased, and potentiation of mIPSCs by positive modulators of GABAR was also reduced compared with control rats. However, mIPSC potentiation by the [alpha]4-preferring benzodiazepine ligands bretazenil and Ro15-4513 was maintained, and increased, respectively. These data suggest that specific alterations in GABAR occur after CIE and may underlie the development of hyperexcitability and ethanol dependence.

Christian, K., M. Lang, et al. (2004). "Interaction of Heterogeneous Nuclear Ribonucleoprotein A1 with Cytochrome P450 2A6 mRNA: Implications for Post-Transcriptional Regulation of the CYP2A6 Gene." *Mol. Pharmacol.* **65**(6): 1405-1414.

<http://molpharm.aspetjournals.org/cgi/content/abstract/65/6/1405>

The human xenobiotic-metabolizing enzyme cytochrome P450, CYP2A6, catalyzes the bioactivation of a number of carcinogens and drugs and is overexpressed in cases of liver diseases, such as cirrhosis, viral hepatitis, and parasitic infestation, and in certain tumor cells. This suggests that CYP2A6 may be a major liver catalyst in pathological conditions. In the present study, we have addressed molecular mechanisms underlying the regulation of the CYP2A6 gene. We present evidence of several proteins present in human hepatocytes that interact specifically with the 3'-untranslated region (UTR) of CYP2A6 mRNA. Biochemical and immunological evidence show that the RNA-protein complex of highest intensity contains the heterogeneous nuclear ribonucleoprotein (hnRNP) A1 or a closely related protein. Mapping of the hnRNP A1 binding site within CYP2A6 3'-UTR reveals that the smallest portion of RNA supporting significant binding consists of 111 central nucleotides of the 3'-UTR. Our studies also indicate that hnRNPA1 from HepG2 cancer cells exhibits modified binding characteristics to the CYP2A6 3'-UTR compared with primary hepatocytes. We found that the level of CYP2A6 mRNA remains high in conditions of impaired transcription in primary human hepatocytes, showing that CYP2A6 expression can be affected post-transcriptionally in conditions of cellular stress. Our results indicate that the post-transcriptional regulation involves interaction of the hnRNP A1 protein with CYP2A6 mRNA. The present data suggest that hnRNPA1 is a critical regulator of expression of the human CYP2A6 gene and support the notion that this P450 isoform may be of particular significance in stressed human liver cells.

Dobelis, P., M. J. Marks, et al. (2002). "A Polymorphism in the Mouse Neuronal alpha 4 Nicotinic Receptor Subunit Results in An Alteration in Receptor Function." *Mol. Pharmacol.* **62**(2): 334-342.

<http://molpharm.aspetjournals.org/cgi/content/abstract/62/2/334>

Nicotine-stimulated 86Rb⁺ efflux and [3H]cytisine binding, both of which seem to measure the nicotinic acetylcholine receptor, composed of [alpha]4 and [beta]2 subunits, were assessed in eight brain regions obtained from 14 inbred mouse strains. The potential role of a single nucleotide polymorphism (SNP) in the nicotinic receptor [alpha]4 subunit gene (Chrna4) on nicotinic receptor binding and function in mice was also evaluated. This SNP leads to an alanine-to-threonine variation at amino acid position 529 of the nascent [alpha]4 subunit polypeptide. Both nicotine-stimulated 86Rb⁺ efflux and [3H]cytisine binding were found to vary across brain regions and among mouse strains. Variability in nicotine-stimulated 86Rb⁺ efflux was positively correlated ($r > 0.9$) within each strain with the number of [3H]cytisine binding sites. However, the number of [3H]cytisine binding sites was not correlated with nicotine-stimulated 86Rb⁺ efflux across mouse strains. In contrast, the Chrna4 polymorphism was associated with receptor function across mouse strains: 86Rb⁺ efflux was greater in seven of the eight brain regions studied in those mouse strains that carry the Ala-529 variant of Chrna4. The Chrna4 SNP did not seem to influence the number of [3H]cytisine binding sites across mouse strains. These data indicate that inbred mouse strains exhibit differences in receptor function that cannot be attributed to variation in receptor expression but may be explained, at least in part, by the missense polymorphism in the [alpha]4 subunit.

Gautam, D., T. S. Heard, et al. (2004). "Cholinergic Stimulation of Salivary Secretion Studied with M1 and M3 Muscarinic Receptor Single- and Double-Knockout Mice." *Mol. Pharmacol.* **66**(2): 260-267.

<http://molpharm.aspetjournals.org/cgi/content/abstract/66/2/260>

Identification of the specific muscarinic acetylcholine receptor (mAChR) subtypes mediating stimulation of salivary secretion is of considerable clinical interest. Recent pharmacological and molecular genetic studies have yielded somewhat confusing and partially contradictory results regarding the involvement of individual mAChRs in this activity. In the present study, we re-examined the roles of M1 and M3 mAChRs in muscarinic agonist-mediated stimulation of salivary secretion by using M1 and M3 receptor single-knockout (KO) mice and newly generated M1/M3 receptor double-KO mice. When applied at a low dose (1 mg/kg, s.c.), the muscarinic agonist pilocarpine showed significantly reduced secretory activity in both M1 and M3 receptor single-KO mice. However, when applied at higher doses, pilocarpine induced only modestly reduced (5 mg/kg, s.c.) or unchanged (15 mg/kg, s.c.) salivation responses, respectively, in M1 and M3 receptor single-KO mice, indicating that the presence of either M1 or M3 receptors is sufficient to mediate robust salivary output. Quantitative reverse transcriptase-polymerase chain reaction studies with salivary gland tissue showed that the inactivation of the M1 or M3 mAChR genes did not lead to significantly altered mRNA levels of the remaining mAChR subtypes. Strikingly, the sialagogue activity of pilocarpine was abolished in M1/M3 receptor double-KO mice. However, salivary glands from M1/M3 receptor double-KO mice remained responsive to stimulation by the β -adrenergic receptor agonist, (S)-isoproterenol. Taken together these studies support the concept that a mixture of M1 and M3 receptors mediates cholinergic stimulation of salivary flow.

Gray, T., P. Nettesheim, et al. (2004). "Interleukin-1 β -Induced Mucin Production in Human Airway Epithelium Is Mediated by Cyclooxygenase-2, Prostaglandin E2 Receptors, and Cyclic AMP-Protein Kinase A Signaling." *Mol. Pharmacol.* **66**(2): 337-346.

<http://molpharm.aspetjournals.org/cgi/content/abstract/66/2/337>

We reported recently that interleukin (IL)-1 β exposure resulted in a prolonged increase in MUC5AC mucin production in normal, well differentiated, human tracheobronchial epithelial (NHTBE) cell cultures, without significantly increasing MUC5AC mRNA (Am J Physiol 286:L320-L330, 2004). The goal of the present study was to elucidate the signaling pathways involved in IL-1 β -induced MUC5AC production. We found that IL-1 β increased cyclooxygenase-2 (COX-2) mRNA expression and prostaglandin (PG) E2 production and that the COX-2 inhibitor celecoxib suppressed IL-1 β -induced MUC5AC production. Addition of exogenous PGE2 to NHTBE cultures also increased MUC5AC production and IL-1 β -induced Muc5ac hypersecretion in tracheas from wild-type but not from COX-2 $^{-/-}$ mice. NHTBE cells expressed all four E-prostanoid (EP) receptor subtypes and misoprostol, an EP2 and EP4 agonist, increased MUC5AC production, whereas sulprostone, an EP1 and EP3 agonist, did not. Furthermore, specific protein kinase A (PKA) inhibitors blocked IL-1 β and PGE2-induced MUC5AC production. However, neither inhibition of epidermal growth factor receptor (EGFR) activation with the tyrosine kinase inhibitor 4-(3-chloroanilino)-6,7-dimethoxyquinazoline HCl (AG-1478) or EGFR blocking antibody nor inhibition of extracellular signal-regulated kinase/P-38 mitogen activated protein kinases with specific inhibitors blocked IL-1 β stimulation of MUC5AC mucin production. We also observed that tumor necrosis factor (TNF)- α , platelet activating factor (PAF), and lipopolysaccharide (LPS) induced COX-2 and increased MUC5AC production that was blocked by celecoxib, suggesting a common signaling pathway of inflammatory mediator-induced MUC5AC production in NHTBE cells. We conclude that the induction of MUC5AC by IL-1 β , TNF- α , PAF, and LPS involves COX-2-generated PGE2, activation of EP2 and/or EP4 receptor(s), and cAMP-PKA-mediated signaling.

Jayanthi, S., M. T. McCoy, et al. (2002). "Methamphetamine Causes Coordinate Regulation of Src, Cas, Crk, and the Jun N-Terminal Kinase-Jun Pathway." Mol. Pharmacol. **61**(5): 1124-1131.

<http://molpharm.aspetjournals.org/cgi/content/abstract/61/5/1124>

The clinical abuse of methamphetamine (METH) is a major concern because it can cause long-lasting neurodegenerative effects in humans. Current concepts of the molecular mechanisms underlying these complications have centered on the formation of reactive oxygen species. Herein, we provide cDNA microarray evidence that METH administration caused the induction of c-Jun and of other members involved in the pathway leading to c-Jun activation [stress-activated protein kinase/Jun N-terminal kinase (JNK3), Crk-associated substrate-Cas and c-Src] after environmental stresses or cytokine stimulation. Reverse transcription-polymerase chain reaction analysis confirmed these increases and also showed that the expression of JNK1 and JNK3 but not JNK2 was also increased in the METH-treated mice. Western blot analysis showed that METH increased the expression of c-Jun phosphorylated at serine-63 and serine-73 residues. Other upstream members of the JNK pathway, including phosphorylated JNKs, mitogen-activated protein kinase kinase 4, mitogen-activated protein kinase kinase 7, Crk II, Cas, and c-Src were also increased at the protein level. These values returned to baseline by 1 week after drug treatment. These results are discussed in terms of their support for a possible role of the activation of the JNK/Jun pathway in the pathophysiological effects of METH.

Kennedy, J. C., S. Memet, et al. (2004). "Antisense Evidence for Nuclear Factor- κ B-Dependent Embryopathies Initiated by Phenytoin-Enhanced Oxidative Stress." Mol. Pharmacol. **66**(3): 404-412.

<http://molpharm.aspetjournals.org/cgi/content/abstract/66/3/404>

Endogenous and xenobiotic-enhanced oxidative stress may initiate embryonic death and birth defects via reactive oxygen species (ROS) signaling pathways involving nuclear transcription factor- κ B (NF- κ B). Using embryo culture and a transgenic mouse engineered with a NF- κ B-dependent β -galactosidase reporter gene, we employed NF- κ B antisense oligonucleotide therapy to determine whether NF- κ B signaling contributes to the embryopathic effects of the ROS-initiating teratogen phenytoin. Phenytoin selectively increased NF- κ B activity in target tissues and caused embryopathies, both of which were blocked by NF- κ B antisense oligonucleotides but not by sense and nonsense oligonucleotide controls. NF- κ B signaling may therefore contribute to the mechanism of ROS-mediated embryopathies.

King, L. M., J. Ma, et al. (2002). "Cloning of CYP2J2 Gene and Identification of Functional Polymorphisms." Mol. Pharmacol. **61**(4): 840-852.

<http://molpharm.aspetjournals.org/cgi/content/abstract/61/4/840>

CYP2J2 is abundant in cardiovascular tissue and active in the metabolism of arachidonic acid to eicosanoids that possess potent anti-inflammatory, vasodilatory, and fibrinolytic properties. We cloned and sequenced the entire CYP2J2 gene (~40.3 kb), which contains nine exons and eight introns. We then sequenced the CYP2J2 exons and intron-exon boundaries in 72 healthy persons representing African, Asian, and European/white populations as part of the National Institutes of Health/National Institute of Environmental Health Sciences Environmental Genome Single Nucleotide Polymorphism Program. A variety of polymorphisms were found, four of which resulted in coding changes (Arg158Cys, Ile192Asn, Asp342Asn, and Asn404Tyr). A fifth variant

(Thr143Ala) was identified by screening a human heart cDNA library. All five variant cDNAs of CYP2J2 were generated by site-directed mutagenesis and expressed in Sf9 insect cells by using a baculovirus system. The recombinant wild-type and variant CYP2J2 proteins immunoreacted with peptide-based antibodies to CYP2J2 and displayed typical cytochrome P450 (P450) CO-difference spectra; however, the Asn404Tyr and Ile192Asn variants also had prominent spectral peaks at 420 nm. The ability of these variants to metabolize arachidonic acid and linoleic acid was compared with that of wild-type CYP2J2. Three variants (Asn404Tyr, Arg158Cys, and Thr143Ala) showed significantly reduced metabolism of both arachidonic acid and linoleic acid. The Ile192Asn variant showed significantly reduced activity toward arachidonic acid only. The Asp342Asn variant showed similar metabolism to wild-type CYP2J2 for both endogenous substrates. Based on these data, we conclude that allelic variants of the human CYP2J2 gene exist and that some of these variants result in a P450 protein that has reduced catalytic function. Insofar as CYP2J2 products have effects in the cardiovascular system, we speculate that these variants may be functionally relevant.

Levresse, V., L. Marek, et al. (2002). "Regulation of Platinum-Compound Cytotoxicity by the c-Jun N-Terminal Kinase and c-Jun Signaling Pathway in Small-Cell Lung Cancer Cells." Mol. Pharmacol. **62**(3): 689-697.

<http://molpharm.aspetjournals.org/cgi/content/abstract/62/3/689>

Cytotoxic platinum compounds including cisplatin are standard cancer chemotherapeutics and are also activators of stress-signaling pathways. In this study, we tested the role of the c-Jun N-terminal kinase (JNK) family of mitogen-activated protein kinases and their transcription factor target, c-Jun, in the cytotoxic response of small-cell lung cancer (SCLC) cells to cisplatin and its less effective trans-isomer, transplatin. Both agents stimulated JNK activity; the transplatin response was rapid and transient, whereas JNK activation by cisplatin was delayed and sustained. Despite the differential kinetics of JNK activation, expression of nonphosphorylatable JNK mutants sensitized the SCLC cells to killing by cisplatin or transplatin, suggesting that JNK activation in response to these agents signals a protective response. Consistent with this finding, overexpression of the JNK target, c-Jun, significantly protected SCLC cells from platinum compounds, whereas expression of a c-Jun mutant encoding only the DNA binding domain increased the sensitivity of the SCLC cells to these drugs. These findings support the hypothesis that activation of the JNKs by platinum compounds controls c-Jun-dependent transcriptional events that promote a protective response in SCLC cells. Oligonucleotide array analysis identified genes encoding a variety of signaling proteins whose expression was reciprocally changed by c-Jun and c-Jun-DBD (c-Jun-DNA binding domain). It is noteworthy that genes whose products are involved in DNA repair, glutathione synthesis, or drug accumulation did not exhibit altered expression by c-Jun or c-Jun-DBD. The findings indicate that inhibition of the JNK pathway is a potential means to enhance the sensitivity of SCLC cells to platinum compounds.

Lin, C. W., M. Nakane, et al. (2002). "trans-Activation and Repression Properties of the Novel Nonsteroid Glucocorticoid Receptor Ligand 2,5-Dihydro-9-hydroxy-10-methoxy-2,2,4-trimethyl-5-(1-methylcyclohexen-3-yl)-1H-[1]benzopyrano[3,4-f]quinoline (A276575) and Its Four Stereoisomers." Mol. Pharmacol. **62**(2): 297-303.

<http://molpharm.aspetjournals.org/cgi/content/abstract/62/2/297>

Glucocorticoids are potent anti-inflammatory and immunosuppressant agents. However, they also produce serious side effects that limit their usage. It has been proposed that anti-inflammatory properties of glucocorticoids are caused mostly by repression of activator protein 1- and nuclear factor [kappa][beta]-stimulated synthesis of inflammatory mediators, whereas most of their

adverse effects are associated with trans-activation of genes involved with metabolic processes. Our laboratories have sought to discover novel glucocorticoid receptor (GR) ligands that have high repression but low trans-activation activities. We describe here cellular properties of 2,5-dihydro-9-hydroxy-10-methoxy-2,2,4-trimethyl-5-(1-methylcyclohexen-3-yl)-1H-[1]benzopyrano[3,4-f]quinoline (A276575) and its four enantiomers. Similar to dexamethasone, A276575 exhibited high affinity for GR and potently repressed interleukin (IL) 1[β]-stimulated IL-6 production in human skin fibroblasts, prostaglandin (PG) E₂ production in A549 human lung epithelial cells, and concanavalin A-induced monocyte proliferation. In contrast to dexamethasone, A276575 caused smaller induction of aromatase activity in human skin fibroblasts and antagonized dexamethasone-induced activation of an mouse mammary tumor virus-glucocorticoid-response element (GRE) reporter gene construct. Among the four enantiomers of A276575, the two ([-])-enantiomers showed 10- to 30-fold higher affinities for GR than their respective (+)-enantiomers. Both ([-])-Syn and ([-])-Anti enantiomers of A276575 were potent inhibitors of IL-1[β]-stimulated PGE₂ production in A549 lung epithelial cells; unexpectedly, however, only the ([-])-Anti enantiomer inhibited regulated on T-cell activation, normal T-cell expressed and secreted (RANTES) production in A549 cells. In summary, A276575 is a novel, nonsteroidal GR ligand that possesses high repression activities against inflammatory mediator production but has lower GRE trans-activation activities than traditional steroids. Differential repression of RANTES and PGE₂ production in a cell by the two ([-])-enantiomers of A276575 illustrates the complexity of repression by GR.

Ma, J., J. Graves, et al. (2004). "Regulation of Mouse Renal CYP2J5 Expression by Sex Hormones." Mol. Pharmacol. **65**(3): 730-743.

<http://molpharm.aspetjournals.org/cgi/content/abstract/65/3/730>

Mouse CYP2J5 is abundant in kidney and active in the metabolism of arachidonic acid to epoxyeicosatrienoic acids. Western blots of microsomes prepared from mouse kidneys demonstrate that after puberty, CYP2J5 protein is present at higher levels in male mice than in female mice. Northern analysis reveals that CYP2J5 transcripts are more abundant in adult male versus female kidneys, indicating that gender differences in renal CYP2J5 expression are regulated at a pretranslational level. Castration of male mice results in decreased renal CYP2J5 expression, and treatment of castrated male mice or female mice with 5 α -dihydrotestosterone increases expression to levels that approximate those in intact male mice. In contrast, treatment of ovariectomized female mice or castrated male mice with 17 β -estradiol causes a further reduction in CYP2J5 expression. Growth hormone-deficient (lit/lit) mice respond similarly to castration and 5 α -dihydrotestosterone treatment, indicating that the androgen effects are not mediated by alterations in the growth hormone secretory pattern. Mice that lack a functional androgen receptor (Tfm hemizygous) have reduced levels of renal CYP2J5 and do not respond to 5 α -dihydrotestosterone treatment. Similarly, wild-type male mice treated with flutamide, an androgen antagonist, exhibit reduced renal CYP2J5 levels. Female estrogen receptor- α knockout (α ERKO) mice, which are known to have elevated circulating testosterone levels, have significantly increased renal CYP2J5 expression compared with wild-type female mice, and these differences are abrogated by ovariectomy or treatment with flutamide. Based on these data, we conclude that the renal expression of CYP2J5 is up-regulated by androgen and down-regulated by estrogen.

Peeters, P. J., H. W. Gohlmann, et al. (2004). "Transcriptional Response to Corticotropin-Releasing Factor in AtT-20 Cells." Mol. Pharmacol. **66**(5): 1083-1092.

<http://molpharm.aspetjournals.org/cgi/content/abstract/66/5/1083>

Corticotropin-releasing factor (CRF) plays a central role in the regulation of the hypothalamic-pituitary-adrenal axis, mediating endocrine and behavioral responses to various stressors. Two high-affinity receptors for CRF have been described. Although many of the intracellular signaling pathways activated by CRF have been studied extensively, our knowledge of transcriptional responses downstream of the CRF receptor 1 (CRFR1) is still limited. To elucidate gene networks regulated by CRF and CRFR1, we applied microarray technology to explore transcriptional response to CRF stimulation. Therefore, mouse pituitary-derived AtT-20 cells were exposed continuously to CRF either in the presence or absence of the specific CRFR1 antagonist R121919. Transcriptional responses to different treatments were studied in a time course ranging from 0.5 to 24 h. Microarray data were analyzed using classic microarray data analysis tools such as correspondence factor analysis, cluster analysis, and fold-change filtering. Furthermore, spectral map analysis was applied, a recently introduced unsupervised multivariate analysis method. A broad and transient transcriptional response to CRF was identified that could be blocked by the antagonist. This way, several known CRF-induced target genes and novel CRF responsive genes were identified. These include transcription factors such as cAMP-responsive element modulator (7x increased), secreted peptides such as cholecystokinin (1.5x), and proteins involved in modulating intracellular signaling, such as regulator of G-protein signaling 2 (11x). Up-regulation of many of these genes can be explained as negative feedback, attenuating CRF-activated pathways. In addition, spectral map analysis proved to be a promising new tool for microarray data analysis.

Siwkowski, A. M., L. A. Madge, et al. (2004). "Effects of Antisense Oligonucleotide-Mediated Depletion of Tumor Necrosis Factor (TNF) Receptor 1-Associated Death Domain Protein on TNF-Induced Gene Expression." Mol. Pharmacol. **66**(3): 572-579.

<http://molpharm.aspetjournals.org/cgi/content/abstract/66/3/572>

Tumor necrosis factor (TNF) receptor 1-associated death domain protein (TRADD) is an adaptor protein known to be involved in the TNF signaling pathway as well as signaling of other members of the TNF receptor superfamily, including DR3, DR6, p75NTR, and the Epstein-Barr virus latent membrane protein 1. Current knowledge of the function of the adaptor protein has been derived from studies examining its over-expression in either wild-type or mutated forms. In this study, we analyzed the consequences of antisense oligonucleotide (ASO)-mediated depletion of endogenous TRADD on TNF induction of inflammation-related gene products, such as intercellular adhesion molecule-1, and associated kinase signaling pathways in human umbilical vein endothelial cells. A broader perspective of TRADD's role in TNF signaling was indicated by microarray gene expression analysis, where 20 of 24 genes that showed a 5-fold or greater increase in TNF-induced mRNA expression levels displayed a reduction in TNF-induced expression as a consequence of ASO-mediated knockdown of TRADD. Reduced activation of the nuclear factor- κ B and c-Jun NH₂-terminal kinase pathways, as measured by I κ B- α protein levels and the extent of c-Jun phosphorylation, was also observed. These results indicate usage of antisense inhibitors of TRADD expression for modulating diseases associated with TRADD-dependent signal transduction pathways.

Soderberg, M., F. Raffalli-Mathieu, et al. (2002). "Inflammation Modulates the Interaction of Heterogeneous Nuclear Ribonucleoprotein (hnRNP) I/Polypyrimidine Tract Binding Protein and hnRNP L with the 3'Untranslated Region of the Murine Inducible Nitric-Oxide Synthase mRNA." Mol. Pharmacol. **62**(2): 423-431.

<http://molpharm.aspetjournals.org/cgi/content/abstract/62/2/423>

Interaction of two members of the heterogeneous nuclear ribonucleoprotein (hnRNP) family with

the 3'untranslated region (UTR) of the murine inducible nitric-oxide synthase (iNOS) mRNA is demonstrated in this study. An iNOS RNA-protein complex is formed using protein extracts from untreated and septic shock treated mouse liver. UV cross-linking reveals that the complex consists of at least two proteins, with apparent molecular masses of 60 and 70 kDa, respectively. The 60-kDa protein binding site lies within a 112-nt pyrimidine-rich sequence, approximately 160 nt from the coding sequence, and the RNA-protein complex can be precipitated by a monoclonal antibody directed against hnRNP I [also named polypyrimidine tract binding protein (PTB)]. The 70-kDa protein binds a 43-nt sequence near the 3'end of the 3'UTR and is immunoprecipitated by a monoclonal antibody against hnRNP L. A computer-simulated conformation of the 3'UTR suggests that both binding sites reside in regions easily accessible for a protein. Supershifts of the native RNA-protein complex could only be achieved with anti-hnRNP L, suggesting that within this multiprotein RNA complex, only hnRNP L is exposed to the antibodies, whereas the hnRNP I/PTB is mainly responsible for its interaction with the mRNA. Up-regulation of iNOS by septic shock reduces the RNA-protein complex formation, thus showing that hnRNP I/PTB and hnRNP L binding to the iNOS mRNA is modulated by inflammation. This suggests a novel function for the two previously described proteins as regulators of the iNOS gene.

Struckmann, N., S. Schwering, et al. (2003). "Role of Muscarinic Receptor Subtypes in the Constriction of Peripheral Airways: Studies on Receptor-Deficient Mice." Mol. Pharmacol. **64**(6): 1444-1451.

<http://molpharm.aspetjournals.org/cgi/content/abstract/64/6/1444>

In the airways, increases in cholinergic nerve activity and cholinergic hypersensitivity are associated with chronic obstructive pulmonary disease and asthma. However, the contribution of individual muscarinic acetylcholine receptor subtypes to the constriction of smaller intrapulmonary airways that are primarily responsible for airway resistance has not been analyzed. To address this issue, we used videomicroscopy and digital imaging of precision-cut lung slices derived from wild-type mice and mice deficient in either the M1 (mAChR1^{-/-} mice), M2 (mAChR2^{-/-} mice), or M3 receptor subtype (mAChR3^{-/-} mice) or lacking both the M2 and M3 receptor subtypes (mAChR2/3^{-/-} double-knockout mice). In peripheral airways from wild-type mice (mAChR^{+/+} mice), muscarine induced a triphasic concentration-dependent response, characterized by an initial constriction, a transient relaxation, and a sustained constriction. The bronchoconstriction was diminished by up to 60% in mAChR3^{-/-} lungs and was completely abolished in mAChR2/3^{-/-} lungs. The sustained bronchoconstriction was reduced in mAChR2^{-/-} bronchi, and, interestingly, the transient relaxation was absent; the bronchoconstriction in response to 10⁻⁸ M muscarine was increased by 158% in mAChR1^{-/-} mice. Quantitative reverse transcriptase-polymerase chain reaction analysis revealed that the disruption of specific mAChR genes had no significant effect on the expression levels of the remaining mAChR subtypes. These results demonstrate that cholinergic constriction of murine peripheral airways is mediated by the concerted action of the M2 and M3 receptor subtypes and suggest the existence of pulmonary M1 receptor activation, which counteracts cholinergic bronchoconstriction. Given the important role of muscarinic cholinergic mechanisms in pulmonary disease, these findings should be of considerable therapeutic relevance.

Molecular and Cellular Endocrinology(61)

Aavik, E., D. d. Toit, et al. (2001). "Estrogen receptor beta dominates in baboon carotid after endothelial

denudation injury." Molecular and Cellular Endocrinology **182**(1): 91.

<http://www.sciencedirect.com/science/article/B6T3G-44GGB9K-B/2/3f4f3a86f3f70012be86a160d3ddf1c8>

Increasing evidence, mainly from rodents, suggests that the predominant estrogen receptor (ER) in arteries is the newly-described ERbeta. We have investigated the expression of the two ERs in baboon carotid artery before and after denudation injury. Prior to denudation, both full length receptors were detected in semiquantitative RT-PCR; in addition two ERalpha but no ERbeta splicing variants were found. After denudation, ERbeta mRNA increased five-fold and declined, whereas ERalpha mRNA expression remained low. Prior to and after denudation, two ERalpha-specific antibodies showed no reaction with the vessel wall. Instead, two affinity purified antisera to ERbeta demonstrated a weak but distinct reaction over vascular smooth muscle cells with predenudation specimens, escalating post-denudation and declining thereafter. The results suggest that selective targeting to ERbeta should be attempted when designing estrogen-based vasculoprotective drug therapies devoid of uterotrophic side effects.

Ando, M., S. Kol, et al. (1999). "Non-steroidal anti-inflammatory drugs (NSAIDs) block the late, prostanoid-dependent/ceramide-independent component of ovarian IL-1 action: implications for the ovulatory process." Molecular and Cellular Endocrinology **157**(1-2): 21.

<http://www.sciencedirect.com/science/article/B6T3G-3XT71FT-3/2/538a578d88e486eachba7322391866333>

The therapeutic efficacy and antiovarian properties of non-steroidal anti-inflammatory drugs (NSAIDs) is attributed to their ability to suppress prostaglandin endoperoxide synthase (PGS) activity. Given the likely role of interleukin (IL)-1 in the inflammatory (and probably the ovulatory) process, we set out to evaluate whether the antiovarian property of NSAIDs is attributable, in part, to the inhibition of ovarian IL-1 action. Whole ovarian dispersates from immature rats were cultured under serum-free conditions in the absence or presence of the indicated agents. At the conclusion of the culture period, total RNA was extracted and probed for transcripts corresponding to PGS-1, PGS-2, IL-1[beta], IL-1 receptor antagonist (IL-1RA) or type I IL-1 receptor (IL-1R) by a solution hybridization/ribonuclease protection assay. Treatment with indomethacin was without significant effect on the early (1 h) response to IL-1[beta]; however, it led to complete and highly significant dose-dependent blockade of the late (48 h) response to IL-1[beta] as assessed in terms of PGS-2 transcripts, proteins and activity. The addition of PGE2 to cells augmented the ability of IL-1[beta] to upregulate PGS-2 transcripts. Moreover, the addition of PGE2 to indomethacin-treated cells all but reversed the ability of indomethacin to suppress the IL-1[beta] effect at both the PGS-2 transcript and protein levels. The upregulation by IL-1 of IL-1[beta], IL-1R and IL-1RA transcripts was similarly inhibited by indomethacin. Taken together, these observations suggest that the anti-ovulatory property of NSAIDs may be due, in part, to blockade of the late, prostanoid-dependent component of ovarian IL-1 action.

Autelitano, D. J., L. Snyder, et al. (1989). "Dopamine D2-receptor messenger RNA is differentially regulated by dopaminergic agents in rat anterior and neurointermediate pituitary." Molecular and Cellular Endocrinology **67**(1): 101.

<http://www.sciencedirect.com/science/article/B6T3G-47GGRXR-F/2/7811f0f6159449df21a8cfbd1a964734>

Hypothalamic dopamine (DA), acting at DA D2-receptors (D2-R) on pituitary target cells,

mediates peptide release and biosynthesis of rat pituitary anterior lobe (AL) prolactin, and neurointermediate lobe (NIL) pro-opiomelanocortin (POMC). We were interested in determining if dopamine agonists and antagonists were capable of modifying D2-R gene expression in these pituitary cells. Utilizing the recently published sequence of the rat D2-R, we isolated a rat D2-R cDNA clone by polymerase chain reaction, and have synthesized RNA probes to quantitate levels of D2-R mRNA by solution hybridization/nuclease protection assay. We report here that 5-day administration of the DA antagonist haloperidol led to significant increase in both D2-R mRNA and POMC mRNA in the NIL; the DA agonist bromocriptine caused a significant decrease in NIL POMC mRNA with no parallel change in D2-R mRNA. In contrast, no significant changes in D2-R mRNA in AL were observed following treatment with either the DA agonist or antagonist. These data provide evidence for tissue-specific regulation of D2-R mRNA in response to dopaminergic manipulation.

Bauer, M. P., J. T. Bridgham, et al. (2000). "Conservation of steroidogenic acute regulatory (StAR) protein structure and expression in vertebrates." Molecular and Cellular Endocrinology **168**(1-2): 119.

<http://www.sciencedirect.com/science/article/B6T3G-41JM913-D/2/623b23032e74b10b54a473808932ba74>

Complementary DNAs for the open reading frames of the chicken, Xenopus and zebrafish StAR homologs were cloned along with a partial cDNA of the zebrafish homolog to MLN64, a StAR-related protein. A comparison of the amino acid sequences of piscine, amphibian, avian and mammalian StARs, indicates strong conservation of the protein across divergent vertebrate groups. On Northern blots probed with species specific StAR cDNAs, expression of StAR transcripts was observed in the ovary and adrenal of chicken, and the ovary, testis, kidney and head of zebrafish. The expression of StAR mRNA in various compartments of the hen ovary was consistent with the results of past studies on steroidogenesis; expression was first observed in follicles selected into the preovulatory hierarchy and was greatest in the largest preovulatory follicle. The expression of StAR mRNA was also consistent with aromatase expression in zebrafish ovaries. The conserved deduced protein sequence and expression pattern of StAR transcripts in chicken and zebrafish tissues, strongly suggest that StAR is also involved in the regulation of steroidogenesis in nonmammalian vertebrates.

Belanger, G., M. Beaulieu, et al. (1995). "Expression of transcripts encoding steroid UDP-glucuronosyltransferases in human prostate hyperplastic tissue and the LNCaP cell line." Molecular and Cellular Endocrinology **113**(2): 165.

<http://www.sciencedirect.com/science/article/B6T3G-3XWRSY9-23/2/4c2e3d7c67c0ec4449759ac8c6511f76>

The UDP-glucuronosyltransferase (EC 2.4.1.17) enzymes transform many lipophilic compounds to more water-soluble products via conjugation with glucuronic acid. This conversion is responsible for enhancing the excretion of endogenous aglycones such as steroids. To date, several distinct isoforms of steroid UDP-glucuronosyltransferases (UGTs) have been isolated in the human liver. Among these UGTs, UGT2B7 is specific for estriol and 3,4-catechol estrogens, UGT2B15 glucuronidates 17[beta]-hydroxy-C19 steroids while UGT2B10 has as yet an undescribed activity. To further demonstrate the presence of UGTs in peripheral tissues we studied the expression of these enzymes in human prostate hyperplastic tissue and the LNCaP cell line. Metabolism studies using intact LNCaP cells in culture indicate the presence of UGT activities involved in the glucuronidation of 3[alpha]-hydroxysteroids (androsterone) and 17[beta]-hydroxysteroids (testosterone and dihydrotestosterone). Northern blot analysis of poly(A+) RNA from LNCaP cells and prostate using a UGT2B15 cDNA probe revealed two bands of 2.0 and 2.3

kb. In order to identify more specifically the mRNAs detected in Northern blot analysis we used RNase protection and RT-PCR assays. The relatively high expression of UGT2B10 and UGT2B15 in LNCaP cells was confirmed by RNase protection and RT-PCR, although, these approaches did not allow detection of UGT2B7 transcripts. Our studies demonstrate the presence of two UGT activities and at least two types of UGT transcripts in both the human prostate and the LNCaP cells.

Bowman, C. J., K. J. Kroll, et al. (2002). "Estradiol-induced gene expression in largemouth bass (*Micropterus salmoides*)."
Molecular and Cellular Endocrinology **196**(1-2): 67.

<http://www.sciencedirect.com/science/article/B6T3G-46THXCK-5/2/3ba70e8424422115541d89cf6e2f0ccc>

Vitellogenin (Vtg) and estrogen receptor (ER) gene expression levels were measured in largemouth bass to evaluate the activation of the ER-mediated pathway by estradiol (E2). Single injections of E2 ranging from 0.0005 to 5 mg/kg up-regulated plasma Vtg in a dose-dependent manner. Vtg and ER mRNAs were measured using partial cDNA sequences corresponding to the C-terminal domain for Vtg and the ligand-binding domain of ER[alpha] sequences. After acute E2-exposures (2 mg/kg), Vtg and ER mRNAs and plasma Vtg levels peaked after 2 days. The rate of ER mRNA accumulation peaked 36-42 h earlier than Vtg mRNA. The expression window for ER defines the primary response to E2 in largemouth bass and that for Vtg a delayed primary response. The specific effect of E2 on other estrogen-regulated genes was tested during these same time windows using differential display RT-PCR. Specific up-regulated genes that are expressed in the same time window as Vtg were ERp72 (a membrane-bound disulfide isomerase) and a gene with homology to an expressed gene identified in zebrafish. Genes that were expressed in a pattern that mimics the ER include the gene for zona radiata protein ZP2, and a gene with homology to an expressed gene found in winter flounder. One gene for fibrinogen [gamma] was down-regulated and an unidentified gene was transiently up-regulated after 12 h of exposure and returned to basal levels by 48 h. Taken together these studies indicate that the acute molecular response to E2 involves a complex network of responses over time.

Breen, J. J., N. J. Hickok, et al. (1997). "The rat TSH[beta] gene contains distinct response elements for regulation by retinoids and thyroid hormone."
Molecular and Cellular Endocrinology **131**(2): 137.

<http://www.sciencedirect.com/science/article/B6T3G-3R7B1MD-2/2/f59e4986d3415a349ffa4ae587cdf40b>

We have previously shown that thyroid stimulating hormone-[beta] (TSH[beta]) mRNA levels are modulated by vitamin A status in vivo and using transient transfection, that suppression of rat TSH[beta] gene promoter activity by all-trans retinoic acid (RA) requires RA receptor (RAR) and retinoid X receptor (RXR). In this paper we have used deletion analysis to delineate the sequences of the rTSH[beta] gene involved in RA regulation, their relationship to the rTSH[beta] gene negative thyroid hormone response elements and the retinoid receptor species that interact with these sequences. Using transient transfection in CV-1 cells, we found that the -204/+9 region of the rat TSH[beta] gene, when fused to a luciferase reporter, was sufficient for suppression by all-trans-RA in the presence of RAR/RXR. Thus, regulation by RA did not involve the major rTSH[beta] negative TRE located between +15 and +43. Mutational analysis also showed that the minor rTSH[beta] negative TRE between -11 and +5 was not required by suppression by RA. However, in a heterologous promoter this sequence element acted as a strong positive RARE. The combination of RA and T3 treatment caused synergistic inhibition of rat TSH[beta] gene expression in the presence of RAR/RXR and TR. EMSA analysis demonstrated that the -204/-79 sequence binds RAR/RXR heterodimer. Therefore, we conclude that there are separate response

elements for RA and T3 on the rat TSH[beta] gene, that the RARE binds RAR/RXR heterodimer and that RA and T3 interact functionally via these elements in the negative regulation of rat TSH[beta] gene expression.

Brevini-Gandolfi, T. A. L., F. Cillo, et al. (2001). "Somatostatin up-regulates topoisomerase II alpha expression and affects LNCaP cell cycle." Molecular and Cellular Endocrinology **176**(1-2): 103.

<http://www.sciencedirect.com/science/article/B6T3G-430NR88-F/2/3dc4d72b66fc7cb61108dacbbd42f59e>

mRNA differential display-PCR analysis was used to perform a systematic screening of Somatostatin (SS)-regulated genes in the human prostatic carcinoma cell line LNCaP (Lymph Node Carcinoma of the Prostate). A 170 bp fragment was shown to be up-regulated by SS. Sequence analysis of this fragment revealed its homology with the human Topoisomerase II Alpha gene. Up-regulation of Topoisomerase II Alpha was confirmed by Northern blot hybridisation and was induced by the same dose of SS (1 nM) earlier demonstrated to inhibit LNCaP cell growth. Furthermore, SS possible effects on timing, as well as concentration of Topoisomerase II Alpha along the different phases of the cell cycle were investigated. To this purpose changes in the enzyme protein concentration in response to SS were assessed in synchronised LNCaP cells. The hormone was shown to exert a perturbing effect on both parameters considered, possibly related to its inhibitory action on LNCaP cell replication.

Celano, M., F. Arturi, et al. (2003). "Expression of adenylyl cyclase types III and VI in human hyperfunctioning thyroid nodules." Molecular and Cellular Endocrinology **203**(1-2): 129.

<http://www.sciencedirect.com/science/article/B6T3G-481N1T0-3/2/b7bbafd099c208fc10751e81385a14a7>

Hyperfunctioning thyroid nodules are characterized by the presence of spontaneous somatic mutations responsible for constitutive activation of the cAMP pathway. However, alterations affecting other elements of the cAMP signaling system may counteract the effects of the mutations. In this study, the expression of the adenylyl cyclase (AC) types III and VI was investigated by Western blot in 18 hyperfunctioning thyroid nodules; in 12 samples, we also assessed the presence of TSH receptor (TSHR) or gsp mutations and levels of AC VI and III mRNA. We found that the expression of nodular AC VI (but not AC III) was significantly lower (85.1% of normal, $P=0.014$) than the expression of both adenylyl cycles types of perinodular tissue from the same patients. Slightly, but not significant differences were detected in nodules with or without mutations and AC protein levels generally showed correlation with the levels of the transcripts detected by RT-PCR. In addition, AC III and AC VI expression levels within a given nodule were characterized by a significant positive correlation. These findings indicate that a diminished expression of AC type VI may be part of the mechanisms occurring in the hyperfunctioning nodules, independently of the presence of TSHR or gsp mutations, which influence the resulting phenotype.

Celi, F. S., G. Canettieri, et al. (1998). "Genomic characterization of the coding region of the human type II 5'-deiodinase gene." Molecular and Cellular Endocrinology **141**(1-2): 49.

<http://www.sciencedirect.com/science/article/B6T3G-3TGVJSC-8/2/5fcb2875c10aea84df387c9083beffb6>

Type II 5'-Deiodinase (5'DII) is a key element in the maintenance of peripheral thyroid hormone homeostasis through the regulation of local T4 to T3 conversion in pituitary, brain, brown adipose tissue and placenta. The cDNA containing the coding region of the human 5'DII (HDII) has been recently cloned from infant brain. In the present paper we report the genomic structure, chromosomal localization and restriction map of the coding region of HDII. The presence of a single intron located at codon 75 was demonstrated using a PCR-based strategy; the exon-intron junctions were then cloned and partially sequenced. Chromosomal localization was performed by radiation hybrid mapping. This study demonstrated that the entire coding region of the HDII gene is contained in two exons spliced at codon 75 by a 7.4 Kb intron and that the HDII chromosomal location is 14q24.3. These data will allow further studies of the role of HDII in the pathophysiology of thyroid homeostasis.

Chatterjee, A., Y. L. Hsieh, et al. (2001). "Molecular cloning of cDNA encoding thyroid stimulating hormone [beta] subunit of bighead carp *Aristichthys nobilis* and regulation of its gene expression." Molecular and Cellular Endocrinology **174**(1-2): 1.

<http://www.sciencedirect.com/science/article/B6T3G-42SGHHC-1/2/88d709127f65a8b7c23d0ea865782b78>

The complementary DNA (cDNA) encoding pituitary thyroid stimulating hormone beta subunit (TSH-[beta]) of bighead carp was cloned and regulation of its gene expression was investigated for understanding phylogenetic divergence and evolution of TSH molecule. The cDNA was obtained from bighead carp pituitary total RNA by reverse transcription and polymerase chain reaction. Oligonucleotide primers were designed from the sequence of common carp. The full length sequence was then obtained by 3' and 5' rapid amplification of cDNA ends (RACE). The full-length sequence consisting of 3' and 5' untranslated regions was 585 bp long. The predicted amino acid sequence consisted of a signal peptide of 19 amino acid residues and a mature TSH [beta] subunit protein of 131 residues. The coding sequences of the cDNAs showed variable percentage homologies with those of other teleosts and vertebrate species. The predicted amino acid sequence shared 71% identity with rainbow trout and salmon, 90% with goldfish, 50% with eel and 94% with common carp in the mature protein region. The percentages of identity in the same region in comparison with bovine, porcine, rat, mouse, human and chicken were only 39, 42, 41, 40, 45 and 46%, respectively. TSH [beta] mRNA expression was found only in the pituitary tissue out of other tissues tested as testis, muscle, brain and heart. For the first time, thyrotropin releasing hormone (TRH) and thyroxine (T4) effects on pituitary TSH mRNA expression were tested in teleosts under in vitro conditions. TRH treatment on pituitary cells increased TSH [beta] mRNA level, while T4 treatment decreased TSH [beta] mRNA level. The present study provides a direct evidence, for the first time that TRH directly upregulates TSH [beta] gene expression in teleosts.

Cheng, J. and J. R. Malayer (1999). "Responses to stable ectopic estrogen receptor-beta expression in a rat fibroblast cell line." Molecular and Cellular Endocrinology **156**(1-2): 95.

<http://www.sciencedirect.com/science/article/B6T3G-3XM2M1R-C/2/be232578da87b1a8294f1275adeb9fb4>

To examine activity of estrogen receptor-beta (ER[beta]) independently of estrogen receptor-alpha (ER[alpha]), retrovirus-mediated gene transfer was used to insert rat ER[beta] into a rat fibroblast cell line (rat-1) that does not ordinarily express ER. Stable expression of ER[beta] in rat-1 cells was validated and then characterized by reverse-transcription polymerase chain-reaction (RT-PCR) analysis to examine the effects of estradiol (E2) treatment on expression of specific target mRNAs. Results were compared with rat-1 cells and a previously constructed rat-

1+ER[alpha] cell line. Progesterone receptor mRNA was not detected in rat-1 cells and was induced by E2 in both rat-1+ER[alpha] and rat-1+ER[beta] cells. Treatment with E2 resulted in an increased rate of cell proliferation ($P<0.05$) in rat-1+ER[alpha] cells, but not in rat-1 or rat-1+ER[beta] cells. Data confirm studies using transient ER expression demonstrating that ER[alpha] and ER[beta] have both discrete and overlapping activity within the same cell type in the presence of the same ligand.

Drews, R. T., R. A. Gravel, et al. (1992). "Identification of G protein [alpha] subunit mutations in human growth hormone (GH)- and GH/prolactin-secreting pituitary tumors by single-strand conformation polymorphism (SSCP) analysis." Molecular and Cellular Endocrinology **87**(1-3): 125.

<http://www.sciencedirect.com/science/article/B6T3G-47MCKGT-N0/2/5303840e55504f7a11c9cdae3daefaca>

We have applied the polymerase chain reaction (PCR) and single-strand conformation polymorphism analysis (SSCP) to detect activating mutations in the Gs[alpha] subunit gene, amplifying genomic DNA extracted from growth hormone (GH)- and GH/prolactin (PRL)-secreting human pituitary tumors. Of 15 tumors tested six contained mutations in the analyzed regions of the Gs[alpha]. SSCP analysis revealed band shift in exon 8 in four GH- and in one GH/PRL-secreting tumors, and in exon 9 in one GH/PRL-secreting tumor. Direct sequencing of PCR reaction products identified the mutations as R201-H, R201-S and R201-C in exon 8 and Q227-L in exon 9. These results show the efficacy of PCR/SSCP analysis in the detection of G protein mutations and extend the generalization that these sites are hot spots in tumor-inducing mutations.

Drury, K. C., M. C. Liu, et al. (2001). "Results on single cell PCR for Huntington's gene and WAVE(TM) product analysis for preimplantation genetic diagnosis." Molecular and Cellular Endocrinology **183**(Supplement 1): S1.

<http://www.sciencedirect.com/science/article/B6T3G-441N4PC-3/2/bb2f89492c2a90dbc09b03dbac3e71fc>

Triple repeat base pair amplification is the basis for a number of prevalent genetic diseases such as Huntington's, Fragile X, Myotonic Dystrophy and others. We have chosen to investigate the use of PCR to amplify a portion of the Huntington's gene in single cells in order to develop a clinical test system for preimplantation genetic diagnosis (PGD). Amplification of CAG triple repeat sequences poses difficulties due to resistance of GC melting for amplification. Special PCR modifications are necessary to carry out the amplification of GC rich areas found in most triple base pair expansions. We have used a modified polymerase chain reaction (PCR) protocol to amplify the expanded repeat sequence of the Huntington's gene with satisfactory efficiency. Detection of the amplified expanded CAG repeats is shown to be possible using both agarose gel electrophoresis and high definition denaturing high pressure liquid (DHPLC) chromatography. The incidence of allele dropout (ADO) is documented.

Faria, T. N., G. J. LaRosa, et al. (1998). "Characterization of genes which exhibit reduced expression during the retinoic acid-induced differentiation of F9 teratocarcinoma cells: involvement of cyclin D3 in RA-mediated growth arrest." Molecular and Cellular Endocrinology **143**(1-2): 155.

<http://www.sciencedirect.com/science/article/B6T3G-3TX5WGR->

In the presence of retinoic acid (RA), F9 murine teratocarcinoma cells differentiate into cells resembling the extra-embryonic endoderm of the early mouse embryo. Using differential hybridization, we have cloned and characterized six cDNAs corresponding to mRNAs that exhibit reduced expression in F9 cells following RA treatment. Two of these cDNAs encode novel genes (REX-2 and REX-3). The other isolated cDNAs encode genes that have been previously described in other contexts: 1-4 (cyclin D3); 2-10 (pyruvate kinase); 2-12 (glutathione S-transferase); and 2-17 (GLUT 3). The mRNA levels of these genes are reduced by RA or RA plus theophylline and cAMP (RACT) only after 48 h of treatment, and continue to decrease at 96 h. The half-lives of these mRNAs are not changed by RA treatment, indicating that these mRNAs may be regulated through a transcriptional mechanism. In isoleucine-deprived cells, which are growth arrested but do not differentiate, the steady state mRNA levels of genes Rex 2, Rex 3, pyruvate kinase and GLUT 3 are not reduced, in contrast to cyclin D3 and glutathione S-transferase. The expression of the REX-2, REX-3, pyruvate kinase, glutathione S-transferase and GLUT 3 genes is reduced by RACT to the same extent in F9 RAR[gamma]^{-/-} and RAR[alpha]^{-/-} lines as in F9-Wt. In contrast, cyclin D3 exhibits lower mRNA expression in F9 RAR[gamma]^{-/-} and RAR[alpha]^{-/-} stem cells, and this mRNA is not decreased by RACT treatment. Overexpression of cyclin D3 blocks the RA-induced growth arrest of F9 cells, indicating that the downregulation of this gene following RA treatment may constitute a necessary step in the cascade of events leading to growth inhibition by RA.

Findlay, I., P. L. Matthews, et al. (2001). "Using MF-PCR to diagnose multiple defects from single cells: implications for PGD." Molecular and Cellular Endocrinology **183**(Supplement 1): S5.

<http://www.sciencedirect.com/science/article/B6T3G-441N4PC-4/2/53ea46b097ff2d67319fceb84769d555>

Single cell genetic analysis is generally performed using PCR and FISH. Until recently, FISH has been the method of choice. FISH however is expensive, has significant misdiagnosis rates, can result in interpretation difficulties and is labour intensive making it unsuitable for high throughput processing. Recently fluorescent PCR reliability has increased to levels at or surpassing FISH whilst maintaining low cost. However, PCR accuracy has been a concern due to allelic dropout. Multiplex PCR can now increase accuracy by using multiple markers for each chromosome to firstly provide diagnosis if markers fail and/or secondly confirm diagnosis. We compare a variety of diagnostic methods and demonstrate for the first time a multiplex PCR system providing simultaneous diagnosis and confirmation of the major aneuploidy chromosomes (21, 18, 13) and sex as well as DNA fingerprint in single cells. We also discuss the implications of using PCR for aneuploidy screening in preimplantation genetic diagnosis.

Funkenstein, B., C. J. Bowman, et al. (2000). "Contrasting effects of estrogen on transthyretin and vitellogenin expression in males of the marine fish, *Sparus aurata*." Molecular and Cellular Endocrinology **167**(1-2): 33.

<http://www.sciencedirect.com/science/article/B6T3G-417ND93-4/2/6305660ecd7eae390a1bd41917c7fb26>

A partial cDNA encoding for the C-terminus of vitellogenin (VTG) was cloned from liver of *Sparus aurata* male treated with 17[beta]-estradiol (E2). E2 treatment of *S. aurata* males resulted in increased synthesis and secretion of VTG protein into the plasma, determined by a specific enzyme-linked immunosorbent assay (ELISA) in a time-dependent manner. While VTG mRNA

was induced by E2 treatment, transthyretin (TTR) mRNA levels were reduced. These data provide the first demonstration that estrogen exhibits contrasting effect on VTG and on TTR gene expression in teleosts.

Griswold, M. D., J.-S. Kim, et al. (2001). "Mechanisms involved in the homologous down-regulation of transcription of the follicle-stimulating hormone receptor gene in Sertoli cells." Molecular and Cellular Endocrinology **173**(1-2): 95.

<http://www.sciencedirect.com/science/article/B6T3G-42D2C93-9/2/b163d07c83f0dd8bb843999c3b1bf580>

The action of follicle-stimulating hormone (FSH) in spermatogenesis is regulated at a fundamental level by controlling the number of competent receptors present at the surface of Sertoli cells. By controlling the number of receptors, the cell is able to modulate the timing and magnitude of subsequent signal transduction in response to FSH. One mechanism of control is the down-regulation of the steady state levels of the FSH receptor gene after exposure to FSH or agents that stimulate or prolong the cAMP signal transduction cascade (homologous down-regulation) in Sertoli cells. The goals of this study were to examine possible mechanisms involved in the down-regulation of mRNA levels of this gene. Analysis of transcription and processing by a PCR-based assay showed that treatment of Sertoli cells with FSH caused at least a 50% reduction of hnRNA for the FSH receptor gene. Reporter genes controlled by 5' flanking sequences of the FSH receptor gene that were transiently transfected into Sertoli cells were not down-regulated. In electrophoretic mobility shift assays (EMSA), cAMP-inducible nuclear protein complex containing c-Fos formed on the activator protein-1/cAMP responsive element-like site located at -216 to -210 in the promoter of the rat FSH receptor gene. We concluded from this study that there was no evidence for the putative role of ICER in the down-regulation of the FSH receptor promoter. In addition, the FSH-induced down-regulation of the transcription of the FSH receptor gene in Sertoli cells was prevented by the treatment of Sertoli cells with trichostatin A prior to the addition of FSH. This experiment coupled with other observations suggested that the down-regulation may be mediated by changes in chromatin structure.

Haidan, A., S. R. Bornstein, et al. (2000). "Expression of adrenocortical steroidogenic acute regulatory (StAR) protein is influenced by chromaffin cells." Molecular and Cellular Endocrinology **165**(1-2): 25.

<http://www.sciencedirect.com/science/article/B6T3G-40XNWF2-4/2/4b0ba37ce58b6c2d8bf1b514467f77b3>

Cell-cell interactions are crucial role for the proper functioning of endocrine glands. We recently demonstrated that interactions of chromaffin and cortical cells are important for adrenocortical steroidogenesis. However, the molecular mechanisms have not been elucidated and it is unclear if this involves acute and/or chronic processes. By Northern analysis and the quantitative technique of TaqMan PCR we investigated whether chromaffin cells influence the regulation of StAR and the peripheral benzodiazepine receptor (PBR), both required for the rate-limiting step, the delivery of cholesterol to the inner mitochondrial membrane. StAR mRNA levels in bovine adrenocortical cells were increased by incubation with chromaffin cell-conditioned medium (CCM). Short-term treatment for 4 h resulted in a greater stimulation (229 $\pm$ 29% of basal, mean $\pm$ SEM) than did longer incubation times of 8 h and 5 days (159 $\pm$ 13 and 177 $\pm$ 24%). Neither short nor a long-term treatment affected PBR expression. Consistently, the major secretion of chromaffin cells, epinephrine dose-dependently stimulated StAR expression with no effect on PBR mRNA. In conclusion, adrenomedullary secretory products are not necessary for the maintenance of PBR expression but facilitate steroid biosynthesis by increasing StAR mRNA

expression and therefore can account for an ACTH-independent regulation of the rate-limiting step in steroidogenesis.

Hakola, K., P. Van der Boogaart, et al. (1997). "Recombinant rat follicle-stimulating hormone; production by Chinese hamster ovary cells, purification and functional characterization." Molecular and Cellular Endocrinology **127**(1): 59.

<http://www.sciencedirect.com/science/article/B6T3G-3RSG33W-7/2/aa6cb501a8cc437099d41b002908aefe>

In order to obtain homologous follicle-stimulating hormone (FSH) for in vivo and in vitro studies in the rat, rat recombinant (rec) FSH was produced in Chinese Hamster Ovary (CHO) cells. The synthesized rat recFSH was purified and subjected to physico-chemical and biological characterization, including a comparison with two rat pituitary (pit) and reference preparations (NIDDK-rFSH I-8 and NIDDK-rFSH-RP2) as well as with human recFSH (Org 32489). The molecular masses of rat recFSH and human recFSH were determined by SDS-polyacrylamide (SDS-PAGE) and were found to be similar, about 40 kD. The pI distribution of rat recFSH is similar to rat pitFSH, and slightly more acidic than human recFSH (3.6-5.6 vs 3.9-5.5, respectively) as determined by isoelectric focussing in immobilized pH gradients. Rat recFSH displayed dose-response curves parallel and in the same dose range as the rat pitFSH in receptor binding and in vitro bioassays. However, the in vivo activities of rat recFSH and rat pitFSH were 8824 and 3051 IU/mg, respectively, determined by the Steelman Pohley assay. Rat (pit and rec) and human FSH are very different. Human recFSH bound to both calf testicular membranes and CHO cells expressing the human FSH receptor (CHO hFSH-R) with about 10-fold higher affinity (K_a) than pituitary and recombinant rat FSH. In in vitro bioassays with immature rat Sertoli cells and CHO hFSH-R cells human recFSH was also about 10-fold more potent than the rat FSH preparations. In the in vitro bioassays with immature rat granulosa cells the difference was about 5-10-fold. These studies indicate that the receptor binding and in vitro activities of rat pitFSH and rat recFSH are similar. The differences in in vivo activity are probably due to the differences in glycosylation. The biological behaviour of rat FSH (pit and rec) is different from that of human FSH. Therefore, if the rat is used as a model for physiology of gonadotropic action, the results may be greatly influenced by the type (species) of hormone preparation used. The availability of homologous hormone preparations is therefore crucial.

Hofslis, E., L. Thommesen, et al. (2002). "Expression of chromogranin A and somatostatin receptors in pancreatic AR42J cells." Molecular and Cellular Endocrinology **194**(1-2): 165.

<http://www.sciencedirect.com/science/article/B6T3G-45V716K-3/2/db2ec71553ddcd75b5a876da3cdf987>

The exocrine pancreatic cell line AR42J is also known to display some neuroendocrine (NE) features. We have extended this fact by showing that AR42J cells express mRNA of chromogranin A (CgA), display immunoreactivity (IR) to CgA, and secrete its cleavage product pancreastatin. A sparse occurrence of typical NE secretion granules, together with only a faint IR to conventional NE markers, indicates that the NE cells are of a poorly differentiated type. CgA promoter reporter plasmid experiments showed that gastrin, epidermal growth factor, and phorbol 12-myristate 13-acetate, induce upregulation of CgA after 24 h. By RT-PCR, it was found that AR42J expresses all of the five subtypes of the somatostatin (SST) receptor (SSTR) family, except SSTR4. The existence of functional SSTRs was confirmed by showing that the SST analog octreotide could inhibit gastrin-induced proliferation. Thus, the AR42J cell line may function as a valuable experimental model to study the regulation of CgA and SSTRs in poorly differentiated NE tumor cells.

Ikeda, M., M. Taga, et al. (1997). "Gene expression of gonadotrophin-releasing hormone, but not its receptor, in human endometrium and decidua." Molecular and Cellular Endocrinology **135**(2): 165.

<http://www.sciencedirect.com/science/article/B6T3G-3S0DFD5-8/2/96dd212255b4864156bd06da63cc68a7>

Gonadotropin-releasing hormone (GnRH) has been reported to exist in extrahypothalamic tissues such as the placenta, gonads and mammary glands. While we have reported the presence of GnRH-mRNA in the rodent uterus, there have been no reports concerning gene expression of GnRH and its receptor (GnRH-R) in human endometrial tissue. In order to investigate the role of GnRH as a local regulator in the human endometrium, we examined the gene for GnRH and GnRH-R in non-pregnant endometrium and decidua of early pregnancy. Using reverse transcriptase-polymerase chain reaction (RT-PCR) and Southern blot analysis we found GnRH-mRNA but not GnRH-R-mRNA transcripts in the human endometrium and decidua at 7-9 weeks gestation. This is the first report that suggests GnRH gene expression in the human endometrium/decidua.

Jansen, E., P. H. Steenbergh, et al. (1991). "Identification of multiple transcription start sites in the human insulin-like growth factor-I gene." Molecular and Cellular Endocrinology **78**(1-2): 115.

<http://www.sciencedirect.com/science/article/B6T3G-47NWG0N-9K/2/f6720eacf0c9e1756cb77eb884c5a1de>

We have localized four transcription initiation sites in the human insulin-like growth factor-I (IGF-I) gene. Two transcription start sites were identified which result in a longer and shorter version of the leader derived from the known exon 1 of the IGF-I gene. Transcription starting at the upstream transcription initiation site results in a leader exon 1 of about 1155 nucleotides (nt), whereas transcription starting at the downstream initiation site results in a leader of about 240 nt. The majority of the transcripts initiate at the latter site. We further identified a region in the human IGF-I gene between exons 1 and 2, which shows a high degree of homology with the rat IGF-I leader exon 1B. By means of the polymerase chain reaction (PCR) we detected human IGF-I mRNAs containing this novel leader. The corresponding exon was designated exon 1B according to the rat IGF-I gene terminology. PCR and RNase protection analyses identified two transcription start sites within this alternative leader exon 1B. Transcription initiated at the most upstream start site results in a leader of about 750 nt, whereas transcription starting at the downstream site is heterogeneous, resulting in leaders of 65-75 nt long. No consensus TATA-box or AT-rich regions are present immediately upstream of all four transcription start sites identified, nor are these regions particularly GC-rich. The IGF-I gene is known to be expressed differentially in a tissue- and development-specific fashion. Differential activation of multiple promoters could very well play a crucial role in IGF-I gene regulation.

Kim, S., H.-J. Shin, et al. (2004). "Genistein enhances expression of genes involved in fatty acid catabolism through activation of PPAR[alpha]." Molecular and Cellular Endocrinology **220**(1-2): 51.

<http://www.sciencedirect.com/science/article/B6T3G-4CHGD3V-3/2/60694f877fd81e42df72e93a40040744>

Although evidences are emerging that dietary isoflavones have beneficial effects in treatment of hyperlipidemia and cardiovascular diseases, the underlying molecular mechanism has not yet been extensively characterized. In this report, we showed that genistein, one of the major isoflavones, increased expression of genes involved in lipid catabolism such as carnitine palmitoyltransferase 1, liver form (CPT1L) in HepG2 cells, when assayed by real-time reverse-transcriptase polymerase chain reactions as well as Western blotting analysis. The increase in mRNA-level of CPT1L after genistein treatment was not changed in the presence of ICI182780, a potent inhibitor of estrogen receptor, suggesting that this effect of genistein was estrogen receptor-independent. Since these genes involved in fatty acid catabolism are considered putative downstream target genes of peroxisome proliferators-activated receptor [alpha] (PPAR[alpha]), we examined whether expression of PPAR[alpha] was modulated by genistein treatment. Interestingly, genistein induced expression of PPAR[alpha] at both mRNA- and protein-level. Further, genistein activated transcriptional activity of PPAR[alpha], when determined by reporter gene analysis, suggesting genistein as a potential ligand for PPAR[alpha]. Taken together, this study provides a picture of the regulatory action of genistein, as an activator of PPAR[alpha] in fatty acid catabolism and potential use of genistein as lipid-lowering agent.

Koedam, J. A., J. J. Smink, et al. (2002). "Glucocorticoids inhibit vascular endothelial growth factor expression in growth plate chondrocytes." Molecular and Cellular Endocrinology **197**(1-2): 35.

<http://www.sciencedirect.com/science/article/B6T3G-46WWBFP-1/2/6a112916f6846868ff41484b949a66d8>

Vascular endothelial growth factor (VEGF) plays an essential role in angiogenesis in the growth plate and ultimately in regulating endochondral ossification. Since longitudinal bone growth is often disturbed in children who are treated with glucocorticoids, we investigated the effects of dexamethasone on VEGF expression by epiphyseal chondrocytes. Cells were cultured from tibial growth plates of neonatal piglets. Using Northern blotting and RT-PCR techniques, the chondrocyte-specific markers aggrecan, collagen II and CD-RAP were detected. Also the glucocorticoid receptor (GR) was expressed. VEGF protein secreted from these cells was examined by ELISA and Western immunoblotting. The VEGF121 and VEGF165 isoforms were detected in the supernatant. As determined by RT-PCR, all three major mRNA splice variants were produced, including the species encoding VEGF189. Dexamethasone (100 nM) inhibited both protein and mRNA expression by approximately 45%. Hydrocortisone (cortisol) and prednisolone also inhibited VEGF secretion, but they were less active than dexamethasone. The inhibitory actions of dexamethasone were almost completely blocked by the GR antagonist Org34116, indicating that the GR mediates these actions. Degradation of the VEGF mRNA was not accelerated by dexamethasone. Therefore, a transcriptional mechanism seems likely. Downregulation of this important growth factor could lead to disruption of the normal invasion of blood vessels in the growth plate, which could contribute to disturbed endochondral ossification and growth.

Koehorst, S. G. A., J. J. Cox, et al. (1994). "Functional analysis of an alternatively spliced estrogen receptor lacking exon 4 isolated from MCF-7 breast cancer cells and meningioma tissue." Molecular and Cellular Endocrinology **101**(1-2): 237.

<http://www.sciencedirect.com/science/article/B6T3G-47NWGNK-JP/2/bfaf52e828405223ab0ccf311aea2ba2>

An alternatively spliced mRNA coding for a variant estrogen receptor (ER) missing exon 4 (ER [Delta]4) was detected in the breast tumor cell line MCF7 and meningioma tissue by using the reversed transcriptase PCR technique. The trans-activational properties of this mutant ER were

assessed in embryo carcinoma P19EC and human choriocarcinoma JEG3 cells by co-transfection of the ER [Delta]4 expression vector with an oxytocin promoter construct containing an estrogen-responsive element. ER [Delta]4 did not trans-activate the oxytocin promoter in either a hormone-dependent or -independent manner. Co-transfection of ER [Delta]4 together with the wtER did not show any interference of ER /gDA4 on the stimulation of the oxytocin promoter by the wtER. ER [Delta]4 was translated in vitro. Its capacity to bind estradiol, and the binding of the variant to a synthetic estrogen-responsive element were compared to those of the wild-type receptor. ER [Delta]4 did not bind to a synthetic estrogen-responsive element, nor did it bind estradiol. Hence, ER [Delta]4 appears to be a silent variant and we speculate that it is without any role in tumor progression.

Krisinger, J., T. Setoyama, et al. (1994). "Expression of calbindin-D9k in the early pregnant rat uterus: Effects of RU 486 and correlation to estrogen receptor mRNA." Molecular and Cellular Endocrinology **102**(1-2): 15.

<http://www.sciencedirect.com/science/article/B6T3G-47MCKW8-TX/2/ddf86b897f940cc8bc6e67b966a5fe39>

Calbindin-D9k (CaBP-9k) is a calcium binding protein expressed at high levels in the rat uterus. The CaBP-9k gene carries an estrogen response element which is involved in the steroid hormone regulation of the gene during the estrous cycle and gestation. The present study was aimed at determining expression of the gene during the first half of pregnancy and to assess the role of progesterone (P4) and the estrogen receptor (ER). Expression of CaBP-9k mRNA was determined by Northern blot analysis during the first 10 days of pregnancy. On pregnancy day 1 (P1), CaBP-9k mRNA levels were relatively high. On P2, 3 and 5 CaBP-9k mRNA decreased to the detection limit using 10 [mu]g total RNA probed with a random primed cDNA. On P10, CaBP-9k transcripts began to reappear at levels of about 30% of P1. Expression of [beta]-actin mRNA displayed a continuous increase during this period with a rapid rise of 240% between P2 and P3. The typical increase of P4 accompanied by moderate changes of estradiol (E2) was determined in serum of experimental groups. When RU 486 at 10 mg/kg was administered as a single s.c. injection on P3, the CaBP-9k down-regulation was rapidly interrupted and mRNA expression became extremely high. The effect was seen maximally at 24 h post injection and was maintained at 48 and 72 h. Expression of [beta]-actin mRNA was increased only moderately at 24 h and was unchanged at 48 and 72 h. Serum P4 remained unaffected by the treatment and E2 displayed a slight increase. When ER mRNA was quantified by reverse transcription/PCR techniques a more than 300% increase was detected in the RU 486 treated rats. These data implicate that P4 in early pregnancy is responsible for down regulation of the CaBP-9k gene in uterus via an indirect effect involving the expression of the estrogen receptor.

Lethimonier, C., M. Tujague, et al. (2002). "Peptide insertion in the DNA-binding domain of fish glucocorticoid receptor is encoded by an additional exon and confers particular functional properties." Molecular and Cellular Endocrinology **194**(1-2): 107.

<http://www.sciencedirect.com/science/article/B6T3G-46HBR4P-1/2/d5f55fa3e8600c50a139216cecb7b947>

The trout glucocorticoid receptor (rtGR) contains an additional sequence of nine amino acids located between the two zinc fingers of the DNA-binding domain (DBD) (Endocrinology 136 (1995) 3774). Polymerase chain reaction on trout genomic DNA and sequencing were performed in the DBD region, demonstrating that this peptide is encoded by an additional exon of 27 nucleotides between the two exons encoding the two zinc fingers of other nuclear receptors. This additional sequence in the rtGR confers a better binding affinity of the receptor to a single GRE,

as shown by gel shift experiments with GST-DBDrtGR fusion proteins, deleted or not of the nine amino acids ([Delta]9). This higher affinity is correlated with a higher constitutive transcriptional activity of the receptor on a reporter gene driven by a single GRE, but not with the ligand-induced transcriptional activity. Nevertheless, on a double GRE, the wild type and rtGR-[Delta]9 are equally active on both constitutive or dexamethasone-induced transcriptional activity. This original DBD structure could have emerged during evolution such as to allow better regulation of glucocorticoid dependent genes in relation to the large spectrum of cortisol physiological functions in fish.

Ma, J. F., L. Nonn, et al. (2004). "Mechanisms of decreased Vitamin D 1[alpha]-hydroxylase activity in prostate cancer cells." Molecular and Cellular Endocrinology **221**(1-2): 67.

<http://www.sciencedirect.com/science/article/B6T3G-4CDS5V6-2/2/665db4b9a84f85b9b341edb60a80fe6f>

Vitamin D 1[alpha]-hydroxylase (1[alpha](OH)ase), which converts the circulating prohormone 25-hydroxyvitamin-D3 (25(OH)D3) to the active 1[alpha]-25-dihydroxyvitamin-D3 (1,25(OH)2D3), is present in normal prostatic epithelium. However, prostate cancer cells, both primary cultured cells and cell lines, have greatly decreased activity of 1[alpha](OH)ase and are therefore resistant to the tumor suppressor activity of circulating 25(OH)D3. We quantitated 1[alpha](OH)ase mRNA and protein levels to investigate mechanism(s) responsible for decreased 1[alpha](OH)ase enzymatic activity in prostate cancer. Prostate cancer cell lines had low 1[alpha](OH)ase mRNA levels. Primary prostate cell cultures derived from normal and cancer tissues had equivalent levels of 1[alpha](OH)ase RNA and protein. Equivalent 1[alpha](OH)ase protein levels were observed in prostate tissue sections containing normal and malignant cells. The protein levels of hsc70, whose homolog intracellular Vitamin D binding protein (IDBP-1) facilitates delivery of 25(OH)D3 to 1[alpha](OH)ase in monkey cells, were equivalent in the normal and cancer cells. Equivalent activity in normal and cancer cells of Vitamin D 24-hydroxylase, a mitochondrial enzyme that also uses 25(OH)D3 as a substrate, further ruled out lack of access to substrate as a basis for low activity of 1[alpha](OH)ase in cancer cells. We conclude that diminished 1[alpha](OH)ase activity in prostate cancer cell lines is through decreased gene expression, whereas decreased activity in primary cultures and tissues is post-translational.

Madsen, M. W., B. E. Reiter, et al. (1995). "Differential expression of estrogen receptor mRNA splice variants in the tamoxifen resistant human breast cancer cell line, MCF-7/TAMR-1 compared to the parental MCF-7 cell line." Molecular and Cellular Endocrinology **109**(2): 197.

<http://www.sciencedirect.com/science/article/B6T3G-3XVH3H7-B/2/0c777ad193865591daf3c2b56d1d5b9f>

Breast cancer patients with an estrogen receptor (ER) positive tumor can be treated with the anti-estrogen tamoxifen, but development of anti-estrogen resistance is a serious problem. We have analyzed a tamoxifen resistant human breast cancer cell line MCF-7/TAMR-1 for alterations in ER which might explain the tamoxifen resistance. The MCF-7/TAMR-1 cells expressed both wildtype ER mRNA and protein, and by RT-PCR we were able to clone ER cDNAs corresponding to the following mRNA splice variants: ER[Delta]E2, ER[Delta]E4, ER[Delta]E5, ER[Delta]E7 and a new double splice variant lacking both exon 4 and 7 (ER[Delta]E4,7). The existence of the ER[Delta]E4,7 variant was confirmed by RNase protection assay. Semi-quantitative RT-PCR revealed that ER[Delta]E2 mRNA was expressed at a higher level in MCF-7/TAMR-1 cells, whereas the ER[Delta]E5 mRNA was expressed at a significantly lower level in MCF-7/TAMR-1 cells compared with MCF-7 cells. The differential expression of the two ER mRNA splice variants indicates that they may be involved in anti-estrogen resistance, although the present knowledge

of their biological function does not provide us with an explanation.

Mantovani, G., S. Corbetta, et al. (2001). "Absence of thyroid transcription factor-1 expression in human parathyroid and pituitary glands." Molecular and Cellular Endocrinology **182**(1): 13.

<http://www.sciencedirect.com/science/article/B6T3G-44GGB9K-2/2/bc435508e32da8b816c81ce744d54dc4>

Thyroid transcription factor-1 (TTF-1), a tissue-specific nuclear transcription factor involved in the embryogenesis and differentiation of human thyroid, lung and brain, has been recently identified in other rat tissues, including parafollicular C cells and parathyroid chief cells. Based on this distribution, a possible role for this factor in calcium homeostasis has been suggested. This study investigated the presence of TTF-1 transcripts and protein in human tissues expressing the calcium sensing receptor (CaSR). Using a RT-PCR technique, complemented by Southern blot analysis, TTF-1 expression was detected in human C cells (two medullary thyroid carcinomas), but not in normal and adenomatous (four adenomas and three hyperplasia) parathyroid, and normal and adenomatous (six adenomas) pituitary tissues. CaSR was expressed in all samples. The absence of expression was confirmed by Western blot. In contrast to previous studies in the rat, this study demonstrates the absence of TTF-1 transcripts in the human adult parathyroid and pituitary glands, although a role for this factor during the ontogeny of these organs cannot be excluded.

Miki, Y., T. Suzuki, et al. (2005). "Steroid and xenobiotic receptor (SXR), cytochrome P450 3A4 and multidrug resistance gene 1 in human adult and fetal tissues." Molecular and Cellular Endocrinology **231**(1-2): 75.

<http://www.sciencedirect.com/science/article/B6T3G-4F9SY7K-1/2/292d2858cd639edba9114f6329864bec>

The steroid and xenobiotic receptor (SXR) has been demonstrated to play an important role in the regulation of the cytochrome P450 3A4 gene (CYP3A4) and multidrug resistance gene 1 (MDR1) by both endogenous and xenobiotic substrates. SXR and its rodent ortholog PXR exhibit marked differences in their ability to be activated by xenobiotic inducers. This suggests that results obtained by rodent models may not always accurately predict responses to the same compounds in humans. SXR expression was demonstrated in the human liver and intestine, but its systemic distribution remains unknown. Therefore in this study, we first characterized the expression of SXR and its target genes CYP3A4, and MDR1 in human adult and fetal tissues using quantitative RT-PCR, immunoblotting, and combined laser capture microscopy and RT-PCR analysis. SXR mRNA and protein are expressed in adult and fetal liver, lung, kidney, and intestine. There is a close association between the expression of SXR and its target genes in all of the tissues examined. The amounts of SXR mRNA in the liver and intestine reached maximal levels in young adults (15-38 years old) and then subsequently decreased to less than half of the maximal levels with aging. These findings demonstrated age-related differences in the body's capacity to metabolize steroids and xenobiotic compounds and suggest an important role for SXR and its target genes, CYP3A4 and MDR1 in this process.

Muthukumar, G. and J. Lenard (1991). "A preproinsulin-like pseudogene from *Neurospora crassa*." Molecular and Cellular Endocrinology **82**(2-3): 275.

<http://www.sciencedirect.com/science/article/B6T3G-47MCJDT-50/2/f59d95f4dd3cd08bdd07c320e55251a4>

A segment of DNA was amplified from the *Neurospora crassa* genome by the polymerase chain reaction using several oligonucleotides coding for highly conserved domains in proinsulin as primers and probe. A genomic clone corresponding to this segment was isolated and the nucleotide sequence was determined. The deduced amino acid sequence of a part of this segment bears remarkable resemblance to preproinsulin, but lacks several requirements for transcription or translation and must therefore be considered to be a pseudogene.

Nicod, J., B. Dick, et al. (2004). "Mutation analysis of CYP11B1 and CYP11B2 in patients with increased 18-hydroxycortisol production." *Molecular and Cellular Endocrinology* **214**(1-2): 167.

<http://www.sciencedirect.com/science/article/B6T3G-4BBHDY4-7/2/05a261e86d2a04511fcf29425a720bce>

Background: In patients with glucocorticoid remediable aldosteronism (GRA), a rare hypertensive disorder caused by the presence of a chimeric aldosterone synthase (CYP11B2) and 11[beta]-hydroxylase (CYP11B1) gene, high level of urinary 18-hydroxycortisol (18OHF) excretion are observed. In some patients with hypertension, increased urinary 18OHF secretion is also found in the absence of the hybrid CYP11B1/CYP11B2 gene. We hypothesised that gene variants of CYP11B1 or CYP11B2 may be linked to this abnormal glucocorticoid production. Methods: The urinary steroid profile was analysed by gas chromatography/mass spectrometry in 429 hypertensive patients and 98 (23%) thereof tested positive for increased 18OHF excretion. After correction for total cortisol excretion, 12 subjects showed an abnormally high 18OHF excretion. For genotyping DNA was obtained from six of these patients. All were tested negative for the hybrid CYP11B1/CYP11B2 gene and were further analysed for mutations in all exons and promoter regions of both CYP11B1 and CYP11B2 by single strand conformation polymorphism (SSCP) and sequencing when appropriate. Results: The genetic analysis of the two genes revealed the presence of nine molecular variants in CYP11B2 and three in CYP11B1. In addition to published polymorphic sites, we identified two new variants in CYP11B2 but no new variants in CYP11B1. The newly identified CYP11B2 mutations are a C/T single nucleotide exchange located in the first intron and a double nucleotide exchange at the 3'-splice site of exon 8. The mutated sequence corresponds to the sequence of CYP11B1 indicating a gene conversion. This suggests that the mutant is not likely to affect splicing. Thus, none of the genetic variants identified explains the high urinary excretion of 18OHF. Conclusions: We present here a complete method for the genetic analysis of the CYP11B1 and CYP11B2 genes. By this method we could not identify genetic variants responsible for a GRA-like phenotype. The presence of high levels of 18OHF should not be used alone as a diagnosis tool for GRA.

Nilsson, E., V. Doraiswamy, et al. (2001). "Expression and action of transforming growth factor beta (TGF[beta]1, TGF[beta]2, TGF[beta]3) in normal bovine ovarian surface epithelium and implications for human ovarian cancer." *Molecular and Cellular Endocrinology* **182**(2): 145.

<http://www.sciencedirect.com/science/article/B6T3G-43YSY4C-1/2/5db8b392819a86b3a0abdfc59c8e159b>

The majority of ovarian tumors are derived from the single layer of epithelial cells on the surface of the ovary termed the ovarian surface epithelium (OSE). Stromal cell-OSE interactions are postulated to be an important aspect of normal OSE biology and the biology of ovarian cancer. Transforming growth factor beta (TGF[beta]) has been shown to often be a mesenchymal cell-

derived growth factor that mediates stromal cell-epithelial cell interactions in a variety of different tissues. The current study investigates the expression and action of TGF[β] isoforms (TGF[β]1, TGF[β]2, and TGF[β]3) in OSE and the underlying stroma in both normal bovine and human tumor tissues. Normal bovine ovaries are similar to human ovaries and are used as a model system to investigate normal OSE and stromal cell functions. All three TGF[β] isoforms and their receptor, transforming growth factor β receptor type II (TGF[β]RII), proteins were found to be detected in the OSE from normal bovine ovaries using immunohistochemistry. Ovarian stromal tissue also contained positive immunostaining for TGF[β] isoforms and TGF[β]RII. RNA was collected from normal bovine OSE and ovarian stromal cells to examine TGF[β] gene expression. TGF[β]1, TGF[β]2, and TGF[β]3 transcripts were detected in both freshly isolated and cultured bovine OSE and stromal cells by a sensitive quantitative polymerase chain reaction assay. TGF[β]1 and TGF[β]2 mRNA levels were found to be present at similar levels in freshly isolated OSE and stroma. Interestingly, TGF[β]3 mRNA levels were significantly higher in freshly isolated OSE than stromal cells. All but TGF[β]3 mRNA in OSE increased when the cells were cultured. Observations indicate that normal bovine OSE and stroma cells express the three TGF[β] isoforms in vivo and in vitro. Human ovarian tumors from stage II, stage III and stage IV cases were found to express TGF[β]1, TGF[β]2, TGF[β]3 and TGF[β]RII protein primarily in the epithelial cell component by immunohistochemistry analysis. The stromal cell component of the human ovarian tumors contained little or no TGF[β] or TGF[β]RII immunostaining. TGF[β] actions on bovine OSE and stromal cells were also investigated. TGF[β] was found to inhibit the growth of OSE, but not stromal cells. To further examine the actions of TGF[β] on OSE, the expression of two growth factors previously shown to be expressed by OSE were analyzed. TGF[β]1 was found to stimulate the expression of both keratinocyte growth factor (KGF) and kit ligand/stem cell factor (KL) by bovine OSE. Therefore, TGF[β] actions on OSE will likely promote a cascade of cell-cell interactions and cellular responses involving multiple growth factors. The effects of regulatory agents on TGF[β] expression by the bovine OSE were examined. Transforming growth factor α (TGF[α]) stimulated TGF[β]1 expression, TGF[β]1 stimulated TGF[β]2 expression, and follicle stimulating hormone (FSH) stimulated TGF[β]3 expression. These results demonstrate that TGF[β] isoforms are regulated differently by the regulatory agents tested. In summary, all the TGF[β] isoforms are differentially expressed by the OSE and TGF[β] appears to have an important role in regulating OSE and possibly stromal-OSE interactions. A complex network of endocrine and paracrine interactions appears to influence the expression and actions of TGF[β] on OSE. Abnormal expression and/or action of TGF[β] is postulated to in part be involved in the onset and progression of ovarian cancer.

Nilsson, E. E., P. Kezele, et al. (2002). "Leukemia inhibitory factor (LIF) promotes the primordial to primary follicle transition in rat ovaries." *Molecular and Cellular Endocrinology* **188**(1-2): 65.

<http://www.sciencedirect.com/science/article/B6T3G-44PVPVK-3/2/c32f6ea6ce39c2dec46ef5d86a13a33b>

In a sexually mature female, primordial follicles continuously leave the arrested pool and undergo the primordial to primary follicle transition. The oocytes increase in size and the surrounding squamous pre-granulosa cells become cuboidal and proliferate to form a layer of cuboidal cells around the growing oocyte. This development of the primordial follicle commits the follicle to undergo the process of folliculogenesis. When the available pool of primordial follicles is depleted reproductive function ceases and humans enter menopause. The current study examines whether leukemia inhibitory factor (LIF) promotes the primordial to primary follicle transition that initiates follicular development. Ovaries from 4 day-old rats were cultured in the absence or presence of LIF or neutralizing antibody to LIF. LIF treatment increased the proportion of follicles that initiated the primordial to primary follicle transition to 59%, compared to 45% in untreated cultured ovaries. The ability of LIF to induce primordial follicle development was enhanced to

greater than 75% by the presence of insulin in the culture medium. Anti-LIF neutralizing antibody reduced the proportion of spontaneous developing primordial follicles. Immunocytochemical studies demonstrated higher levels of LIF protein in the granulosa and surrounding somatic cells of primordial and primary follicles compared to the oocyte. In contrast, later pre-antral and antral stage follicles showed LIF expression primarily in the oocyte. In granulosa and theca cell cultures LIF had no effect on cell proliferation. However, LIF treatment did increase expression of Kit ligand (KL) mRNA in cultured granulosa cells. KL has been shown to promote ovarian cell growth and induce primordial follicle development. LIF induction of KL expression may be involved in the actions of LIF to promote primordial to primary follicle transition. In summary, LIF treatment increased the primordial to primary follicle transition in cultured ovaries and LIF may interact with KL to promote primordial follicle development.

Nilsson, E. E. and M. K. Skinner (2004). "Kit ligand and basic fibroblast growth factor interactions in the induction of ovarian primordial to primary follicle transition." Molecular and Cellular Endocrinology **214**(1-2): 19.

<http://www.sciencedirect.com/science/article/B6T3G-4BDM4B2-7/2/e91c96ad2af742c2a4c6aa16f7046f49>

Ovulated eggs during a female's reproductive life are derived from a pool of primordial follicles arrested in prophase of the first meiotic division. When follicles leave the resting pool they undergo a primordial to primary follicle transition and will grow and develop until either ovulation occurs or follicles undergo atresia. Several growth factors have been implicated as acting locally within the ovary to regulate the primordial to primary follicle transition. How these growth factors may interact and cooperate to perform this vital function remains to be elucidated. The objective of the current study is to investigate interactions between kit ligand (KL) (i.e. stem cell factor) and basic fibroblast growth factor (bFGF) that promote the primordial to primary follicle transition in rat ovaries. Ovaries were removed from 4-day-old rat pups and cultured for 2 weeks with KL alone or with KL and a neutralizing antibody against bFGF. The ability of KL treatment to increase primordial follicle transition was blocked with a bFGF neutralizing antibody. In addition, ovary cultures were treated with bFGF alone or with bFGF and an anti-c-kit receptor antibody which blocks KL signaling. The ability of bFGF treatment to increase primordial follicle transition was blocked with an anti-c-kit receptor antibody. Observations indicate that both KL and bFGF must be active in order to optimally promote the changes that occur in oocytes, granulosa cells, and stromal/interstitial cells when primordial follicles initiate development. Cultured ovaries were treated with either KL or bFGF for 3 days and then bFGF and KL mRNA expression levels in the whole ovary were measured. KL was not found to regulate bFGF expression. In contrast, bFGF treatment was found to increase KL mRNA expression in cultured ovaries. These observations suggest that one function of the oocyte-derived bFGF is to increase the granulosa derived KL expression and that both KL and bFGF are required to optimally promote primordial to primary follicle transition. Elucidating the cell-cell interactions that mediate this network of specific locally derived growth factors is critical to understanding the physiology of the primordial to primary follicle transition.

Nogues, N., E. Magnan, et al. (1998). "Expression of a fusion gene consisting of the mouse growth hormone-releasing hormone gene promoter linked to the SV40 T-antigen gene in transgenic mice." Molecular and Cellular Endocrinology **137**(2): 161.

<http://www.sciencedirect.com/science/article/B6T3G-3T14BKT-8/2/289e12d7bb6e2c9477eeec20189f618f>

Limited information is available concerning the regulation of growth hormone-releasing hormone

(GHRH) gene expression in the hypothalamus, largely because of the lack of a suitable cellular model. In an attempt to immortalize hypothalamic GHRH-producing neurons, we have generated a transgenic mouse model which expresses the simian virus 40 (SV40) T-antigen gene (Tag) under the control of the GHRH gene promoter. The transgene contains [ap]5 kb of mouse GHRH gene sequences, including 3.5 kb of the 5'-flanking region, the entire hypothalamic exon 1 and 1.5 kb of intron 1, fused to the SV40 Tag gene. This construct was microinjected into fertilized oocytes. Fourteen of 96 mice born had integrated the transgene. These mice were fertile and showed no signs of central or peripheral tumors. The pattern of expression of the SV40 Tag gene was analyzed in four different transgenic lines by RT-PCR. The tissues tested include: hypothalamus, pituitary, cortex, cerebellum, spinal cord, adrenal, testis, spleen and lung. Transgene expression was consistently detected in the hypothalamus of all lines. In addition, SV40 Tag expression was also detected in the hypothalamus by Northern blot analysis in two of the transgenic lines. SV40 Tag expression was also detected in the testis of all transgenic lines by RT-PCR. This result was not expected since the GHRH gene sequences present in the transgene do not include the testis-specific transcription initiation site previously described. This suggests that GHRH gene expression in the mouse testis can be directed by regulatory sequences located downstream of the testis specific transcription start site. We conclude that the promoter region of the GHRH gene included in this construct contains the regulatory elements necessary to drive hypothalamic and testis expression in vivo. In addition, all mice from one of the transgenic lines developed cataracts in both eyes. SV40 Tag expression was detected not only in eyes with cataracts, but also, to a lesser extent, in eyes from other transgenic lines. Furthermore, the endogenous GHRH gene was found to be expressed in the eyes of normal mice.

Okazaki, T., M. Nishibori, et al. (2003). "LH reduces proliferative activity of cumulus cells and accelerates GVBD of porcine oocytes." Molecular and Cellular Endocrinology **209**(1-2): 43.

<http://www.sciencedirect.com/science/article/B6T3G-49SFKB2-2/2/cbf44e02924441edf68c87c37594aa4b>

It has been reported that LH receptor (LHR) mRNA is not detected in cumulus cells of porcine cumulus-oocyte complexes (COCs) just after collection from small antral follicles. The present study showed that the formation of LHR in cumulus cells was up-regulated by the cultivation with 20 ng/ml FSH. When the newly synthesized receptors were stimulated by 1.0 [mu]g/ml LH, significantly higher levels of cAMP and progesterone production in cumulus cells were observed as compared with those of COCs cultured with FSH. A loss of proliferative activity of cumulus cells was induced by the additional LH to FSH-containing medium; however, the inhibitory effect was overcome by progesterone receptor antagonist RU486. Furthermore, the addition of LH also accelerated ongoing GVBD in cumulus cells-enclosed oocytes. These results revealed that during in vitro meiotic maturation of porcine COCs, progesterone secreted by FSH- and LH-stimulated cumulus cells reduced proliferative activity of cumulus cells; the changes of cumulus cells might be involved in inducing meiotic resumption of porcine oocytes.

Pan, B., K. Sengoku, et al. (2004). "Differential expression of heparin-binding epidermal growth factor-like growth factor in the rat ovary." Molecular and Cellular Endocrinology **214**(1-2): 1.

<http://www.sciencedirect.com/science/article/B6T3G-4BHCSPV-5/2/7320a52c8d11166f511f6aa8a62e4c6b>

We investigated the expression of heparin-binding epidermal growth factor-like growth factor (HB-EGF) and its receptors in the rat ovary to define the role of HB-EGF in the ovarian function. The expression pattern of HB-EGF mRNA and protein were studied by semi-quantitative RT-PCR and immuno-histochemistry using an antibody that was specifically stained for the precursor form of

HB-EGF in naturally cycling rats and immature pseudo-pregnant rat models. The immuno-histochemical study showed that in naturally cycling rats, HB-EGF was expressed in most granulosa cells of early follicles and all the developing follicles but not in preovulatory follicles. This was supported by the semi-quantitative RT-PCR results in that the lowest level of HB-EGF mRNA during the estrous cycle was found in the evening of proestrous when the HB-EGF negative preovulatory follicles were most prominent. The results suggest that HB-EGF might be a mitogen for granulosa cells and down regulation of its expression may be necessary for the final maturation of follicles. In corpora lutea, luteal cells of older generation stained stronger than those of younger generation. Moreover, luteal cells of late luteal phase stained stronger than those of the mid and early luteal phases in the immature pseudo-pregnant rat models, indicating that the precursor form may be associated with death of luteal cells. Finally, of the two cognate receptors for HB-EGF, erbB1 was expressed in the rat ovary, but erbB4 was specifically not expressed in this organ. The spatial and temporal pattern of HB-EGF expression suggest that HB-EGF may an important local regulator of ovarian function and structure.

Parrott, J. A., V. Doraiswamy, et al. (2001). "Expression and actions of both the follicle stimulating hormone receptor and the luteinizing hormone receptor in normal ovarian surface epithelium and ovarian cancer." Molecular and Cellular Endocrinology **172**(1-2): 213.

<http://www.sciencedirect.com/science/article/B6T3G-427JWGY-1W/2/019fab2cefdb0e017de6b393c2921817>

The ability of gonadotropins to act on and regulate normal ovarian surface epithelial (OSE) cells and ovarian cancer cells was investigated. Bovine OSE was used as a model to study normal OSE. Results demonstrate that follicle stimulating hormone (FSH) and the luteinizing hormone (LH) like molecule, human chorionic gonadotropin (hCG), can both stimulate (3H)-thymidine incorporation into DNA in normal OSE cells. Similar results were obtained using either purified hormones or recombinant human hormones. A human ovarian cancer cell-line OCC1 was also stimulated to grow in response to FSH and hCG, but the growth of a different human ovarian cancer cell-line SKOV3 was not affected. In addition to effects on cell growth, gonadotropins also stimulated growth factor expression. Both FSH and hCG stimulated steady state levels of keratinocyte growth factor (KGF), hepatocyte growth factor (HGF), and kit ligand (KL) mRNA in OSE cells. Previously, KGF, HGF, and KL have been shown to stimulate OSE growth. Both follicle stimulating hormone receptor (FSHR) and luteinizing hormone receptor (LHR) were observed in OSE cells by Northern blot analysis. Reverse transcription polymerase chain reaction (RT-PCR) analysis was performed on fresh and cultured OSE cells. Normal OSE was found to express FSHR and LHR both in vivo and in vitro. The PCR reaction products were sequenced and found to provide a 100% homology with the bovine gonadotropin receptor sequences previously reported. FSHR and LHR transcripts were also detected in gonadotropin responsive OCC1 cells, but not in the gonadotropin insensitive SKOV3 cells. Observations support the hypothesis that gonadotropins may influence some ovarian cancers. In summary, the current study demonstrates the novel observation that both the FSHR and LHR are expressed by bovine OSE and selected ovarian cancers. Interestingly, the actions of FSH and LH to promote OSE growth may in part be mediated indirectly through an elevation in the expression of autocrine growth factors (KGF, HGF, and KL). Ovarian cancer is more common in conditions with elevated gonadotropins such as post-menopausal women. Therefore, gonadotropin actions on the OSE are postulated to be a potential factor in the onset and progression of some ovarian cancers.

Parrott, J. A., G. Kim, et al. (2000). "Expression and action of keratinocyte growth factor (KGF) in normal ovarian surface epithelium and ovarian cancer." Molecular and Cellular Endocrinology **167**(1-2): 77.

<http://www.sciencedirect.com/science/article/B6T3G-417ND93-8/2/7f5c9c567b7ee804149815b5eaf57aa9>

The current study investigates the expression and action of keratinocyte growth factor (KGF) in normal ovarian surface epithelium (OSE) and ovarian cancer tissues. Ovarian tumors are primarily derived from the OSE. KGF is a mesenchymal cell-derived growth factor that mediates stromal cell-epithelial cell interactions in a variety of different tissues. Human ovarian tumors from borderline, stage I and stage III cases were found to express KGF protein in the epithelial cell component by immunocytochemical analysis. The stromal cell component of human ovarian tumors contained little or no KGF immunostaining. Normal bovine ovaries have similarities to human ovaries and are used as a model system to investigate normal OSE functions. KGF protein was detected in the OSE from normal human and bovine ovaries by immunocytochemistry. Ovarian stromal tissue contained light but positive KGF immunostaining. RNA was collected from normal bovine OSE and ovarian stromal cells to examine KGF gene expression. KGF transcripts were detected in cultured OSE and stromal cells by Northern blot analysis. In order to examine and quantitate KGF gene expression in freshly isolated versus cultured tissues, a sensitive quantitative RT-PCR assay for KGF was utilized. KGF gene expression was found to be high in freshly isolated OSE, but very low in freshly isolated stroma. Levels of KGF gene expression after culture of OSE and stromal cells increased. Observations indicate that normal OSE express high levels of KGF in vivo and in vitro. Expression of KGF by normal epithelial cells versus stromal cells was unexpected and suggests KGF may be an important autocrine stimulator of OSE. KGF actions on bovine OSE cells were investigated. KGF was found to stimulate the growth of normal OSE cells to the same level as epidermal growth factor. Two ovarian cancer cell lines, SKOV3 and OCC1, were also stimulated to proliferate in response to KGF. Current results demonstrate the production and action of KGF on normal OSE cells and ovarian cancer cells. Observations can be interpreted to suggest that KGF may in part be involved in the growth of ovarian tumors. This appears to be one of the first reports of KGF production by an epithelial cell. The autocrine stimulation of OSE growth by the local production and action of KGF provides insight into how the OSE may develop abnormal growth characteristics involved in the onset and progression of ovarian cancer.

Roy, R. N., A. Cecutti, et al. (1997). "Endometrial transcripts of human insulin-like growth factors arise by differential promoter usage." Molecular and Cellular Endocrinology **135**(1): 11.

<http://www.sciencedirect.com/science/article/B6T3G-3RSN3V8-2/2/95396995e11007bcd62a80b11c2ea2d2>

By the application of RT-PCR, we have demonstrated that in the human endometrium mRNAs for insulin-like growth factors, IGF-I and II, and their receptors are expressed not only in the intact endometrium, but also in the freshly isolated stromal and epithelial cells. The expression of multiple transcript forms of the IGF-I and II at various phases of the menstrual cycle, occurs by differential use of all four IGF-I transcriptional start sites, and two of the four known promoter sites of the IGF-II gene. The complete spectrum of transcripts is displayed by the proliferative phase and the menstrual phase endometrium. During the secretory phase, the exon 1 upstream start site of the IGF-I gene and the P2 promoter of the IGF-II gene are not used. Irrespective of the phase of the menstrual cycle, the stromal cells always display the same transcriptional patterns of both growth factor genes as those of the intact endometrium. In contrast, the epithelial cells do not express IGF-I transcript originating from the exon 2 upstream initiation site. These results indicate that the expressions of the IGF-I and II genes in the intact endometrium and stromal and epithelial cells are modulated at the transcriptional level during the menstrual cycle by differential usage of promoters and start sites.

Roy, R. N., A. H. Gerulath, et al. (1999). "Discordant expression of insulin-like growth factors and their receptor messenger ribonucleic acids in endometrial carcinomas relative to normal endometrium." Molecular and Cellular Endocrinology **153**(1-2): 19.

<http://www.sciencedirect.com/science/article/B6T3G-3WWDH35-3/2/a4b6e34802c7bd57fd54c69d3c06f604>

The inappropriate expressions of insulin-like growth factors (IGF-I and II) and IGF-I receptor (IGF-IR) are implicated in the malignant growth of many cancers. To determine changes, if any, in the levels of expression of IGFs and IGF receptor genes in neoplastic endometrium, relative to normal endometrium, the mRNA levels of IGF-I and II and of IGF-IR and IIR were measured in samples of endometrial carcinomas (EC) and normal endometrium, through all phases of the menstrual cycle, by semiquantitative reverse transcription-polymerase chain reaction (RT-PCR) assays. In normal endometrium, the mRNA levels of IGF-I were elevated in the proliferative and early secretory phases. The IGF-II mRNAs were relatively high in the proliferative phase, but unaltered through early and late secretory phases. Significantly elevated levels of IGF-II transcripts were observed during the menstrual phase, suggesting a possible role of IGF-II in endometrial regeneration. A positive correlation between the levels of IGF-I and IGF-IR mRNAs, apparent in the samples of normal endometrium, was not observed in endometrial carcinomas. The IGF-IR and IIR mRNA levels were elevated in endometrial carcinoma samples. On the other hand, the IGF-I and II mRNA levels were conspicuously low in many carcinoma samples, which were not associated with hyperplasia (type II EC), but relatively elevated in two other carcinoma samples, associated with adenomatous hyperplasia (type I EC). These results albeit with few samples suggest the possibility that the overexpressed receptor, IGF-IR, could be activated differently in two types of endometrial carcinomas, namely ligand-dependently in type I ECs and ligand-independently in type II ECs.

Rudolph, A. E., E. R. Blasi, et al. (2000). "Tissue-specific corticosteroidogenesis in the rat." Molecular and Cellular Endocrinology **165**(1-2): 221.

<http://www.sciencedirect.com/science/article/B6T3G-40XNWF2-V/2/fe5cbf222279fd98a755e70b656acb>

The steroid aldosterone plays a major role in the maintenance of total body sodium homeostasis and also contributes to cardiovascular pathophysiology by mediating cardiac hypertrophy and fibrosis. In addition to classical adrenal production of aldosterone, endogenous tissue production of aldosterone has been observed in various organs; aldosterone biosynthesis in cardiac tissues, however, remains highly controversial. The current study provides a comprehensive evaluation of steroid hormone biosynthetic capabilities in multiple tissues from two distinct rat strains under unstimulated and stimulated conditions. Panels of tissues from Wistar and Sprague-Dawley rats were probed for 11 [beta]-hydroxylase (P45011[beta]) and aldosterone synthase (P450aldo) by reverse transcriptase-polymerase chain reaction (RT-PCR). Under unstimulated conditions, cardiac P45011[beta] and P450aldo were detected only in Wistar rats. Angiotensin II (100 [mu]g/day) stimulated myocardial expression of both enzymes in both strains. Cerebral cortex and mesenteric artery message levels in both strains was reduced by angiotensin II. These data demonstrate the potential for local steroid synthesis in vascular, cardiac, renal, and neuronal tissues, and that biosynthesis of non-adrenal aldosterone may be differentially regulated between strains. This variability may thus resolve in part or whole the current controversy over the existence of non-adrenal steroidogenic systems.

Sabo-Attwood, T., K. J. Kroll, et al. (2004). "Differential expression of largemouth bass (*Micropterus salmoides*) estrogen receptor isotypes alpha, beta, and gamma by estradiol." Molecular and

Cellular Endocrinology **218**(1-2): 107.

<http://www.sciencedirect.com/science/article/B6T3G-4BV484D-1/2/e7c0b4fe059dbd9dfc82ef7c70360463>

The expression levels of three estrogen receptor (ER) isotypes alpha, beta, and gamma were quantified in female largemouth bass (*Micropterus salmoides*) (LMB) liver, ovary, brain, and pituitary tissues. ER alpha and beta expression predominated in the liver, while ERs beta and gamma predominated in the other tissues. Temporally in females, ER alpha was highly up-regulated, ER gamma was slightly up-regulated, and ER beta levels remained unchanged in the liver when plasma 17-[beta] estradiol (E2) and vitellogenin (Vtg) levels were elevated in the spring. In ovarian tissue from these same fish, all three ERs were maximally expressed in the fall, during early oocyte development and prior to peak plasma E2 levels. When males were injected with E2, ER alpha was highly inducible, ER gamma was moderately up-regulated, and ER beta levels were not affected. None of the ER isotypes were induced by E2 in gonadal tissues. These results combined suggest that the ERs themselves are not regulated in the same manner by E2, and furthermore, do not contribute equally to the transcriptional regulation of genes involved in fish reproduction such as Vtg.

Salameh, W., M. Choucair, et al. (2005). "Leydig cell hypoplasia due to inactivation of luteinizing hormone receptor by a novel homozygous nonsense truncation mutation in the seventh transmembrane domain." Molecular and Cellular Endocrinology **229**(1-2): 57.

<http://www.sciencedirect.com/science/article/B6T3G-4DW3CTN-1/2/30559f4b88b821ae45af0bd78aa5f09b>

Inactivating mutations in the LH receptor are the predominant cause for male pseudohermaphroditism in subjects with Leydig cell hypoplasia (LCH). The severity of the mutations, correlates with residual receptor activities. Here, we detail the clinical presentation of one subject with complete male pseudohermaphroditism and LCH. We identify within the proband and her similarly afflicted sibling a homozygous T to G transversion at nucleotide 1836 in exon 11 of the LH/CGR gene. This causes conversion of a tyrosine codon into a stop codon at codon 612 in the seventh transmembrane domain, resulting in a truncated receptor that lacks a cytoplasmic tail. In vitro, in contrast to cells expressing a normal LHR, cells transfected with the mutant cDNA exhibit neither surface binding of radiolabeled hCG nor cAMP generation. In vitro expression under the control of the LHR signal peptide of either a wild type or mutant LHR-GFP fusion protein shows no differences in receptor cellular localization. In conclusion, the in vitro studies suggest that residues in the seventh transmembrane domain and cytoplasmic tail are important for receptor binding and activation without playing a major role in receptor cellular trafficking.

Saward, L. and P. Zahradka (1996). "Insulin is required for angiotensin II-mediated hypertrophy of smooth muscle cells." Molecular and Cellular Endocrinology **122**(1): 93.

<http://www.sciencedirect.com/science/article/B6T3G-3W3NFG8-9/2/c2184a3931196634ffc2aa99e5ae0f7d>

The prevalence of hypertension and atherosclerosis among subjects with hyperinsulinemia supports the premise of a direct metabolic link between insulin and angiotensin II at the cellular level. In the present study, the effect of insulin on the angiotensin II-induced growth of A10 smooth muscle cells (SMC) was investigated. Treatment of quiescent A10 cells with angiotensin II caused an increase in RNA synthesis, proto-oncogene c-fos mRNA levels and cell size

dependent upon pretreatment with insulin. The insulin requirement was independent of its actions as a growth factor, since a pre-treatment of at least 24 h with insulin was essential for growth stimulation by angiotensin II. Using RT-PCR, insulin was shown to regulate AT2 receptor expression in both quiescent and differentiating cells. These data suggest the AT2 receptor, which mediates the growth effects of angiotensin II in A10 cells, may be the critical target for the effect of insulin.

Scaldaferri, L., K. Arora, et al. (1996). "Expression of PACAP and its type-I receptor isoforms in the rat ovary." Molecular and Cellular Endocrinology **117**(2): 227.

<http://www.sciencedirect.com/science/article/B6T3G-3VXN39T-G/2/67461a1765a47657b9f38c8930175915>

Pituitary adenylate cyclase-activating polypeptide (PACAP) is a member of the secretin/glucagon/vasoactive intestinal peptide (VIP)/growth hormone releasing hormone (GHRH) family of neuropeptides, several of which stimulate steroidogenesis in ovarian granulosa cells. PACAP receptors are of two major subtypes; the type I receptor (PACAP-I-R) has much higher affinity for PACAP than VIP, and the type II receptor (PACAP-II-R) has similar affinity for both peptides. In the rat ovary, expression of the PACAP gene was demonstrated by amplification of ovarian RNA by the reverse transcription/polymerase chain reaction (RT-PCR). In addition, hybridization of Northern blots of rat ovarian poly(A)⁺ RNA with a 706-nt rat hypothalamic PACAP-I-R cDNA probe revealed the presence of a 7.0 kb PACAP receptor transcript, similar to that detected in brain and hypothalamus. RT-PCR using specific primers for the PACAP-I-R gene yielded products of the expected size with RNA obtained from ovarian tissue, brain, and hypothalamus. The authenticity of the PCR products was confirmed by Southern blotting and nested PCR, which revealed at least three splice variants of the PACAP-I-R in the rat ovary. These findings demonstrate that both PACAP and PACAP-I-R isoforms are expressed in the rat ovary, where they could exert autocrine or paracrine actions on granulosa cell function.

Sermon, K., S. Seneca, et al. (2001). "PGD in the lab for triplet repeat diseases -- myotonic dystrophy, Huntington's disease and Fragile-X syndrome." Molecular and Cellular Endocrinology **183**(Supplement 1): S77.

<http://www.sciencedirect.com/science/article/B6T3G-441N4PC-K/2/78f500fdb12933f9859b4b869f595ae8>

Myotonic dystrophy (DM), Huntington's disease (HD) and Fragile X syndrome (FRAXA) are three monogenic disease which are caused by so-called dynamic mutations. These mutations are caused by triplet repeats inside or in the vicinity of the gene which have the tendency to expand beyond the normal range thus disrupting the normal functioning of the gene. We describe here our experiences from 1995 to May 2000 with PGD for these three triplet repeat diseases.

Seuntjens, E., H. Vankelecom, et al. (1999). "Targeted ablation of gonadotrophs in transgenic mice affects embryonic development of lactotrophs." Molecular and Cellular Endocrinology **150**(1-2): 129.

<http://www.sciencedirect.com/science/article/B6T3G-3WM5C4D-G/2/4b4da433827bf8df70281e05366cc6f6>

Ablation of pituitary gonadotrophs was obtained in transgenic mice expressing diphtheria toxin A (DTA) under control of the -313/+48 bovine glycoprotein hormone [alpha]-subunit ([alpha]SU) promoter, previously shown to be active in mouse gonadotrophs but not in thyrotrophs. Development of hormone-producing cell types was assessed on the day of birth by computer-assisted image analysis on paraffin-embedded, immunostained pituitary sections. Six out of 50 transgenic F0 ('founder') mice (3 males and 3 females) showed a nearly complete disappearance of gonadotrophs but not of thyrotrophs. The number of lactotrophs and the relative area occupied by PRL-immunoreactivity were significantly reduced in the gonadotroph-depleted mice. The size of lactotroph clusters was smaller in the absence of gonadotrophs. The number and immunoreactive area of corticotrophs and somatotrophs, on the other hand, were not significantly affected by gonadotroph ablation. Based on the reported evidence that fetal ovaries do not produce steroid hormones as a result of lack of expression of at least three of the steroidogenic enzymes, P450scc, P450c17, and P450arom, the present observations can hardly be explained by a decline in estrogen levels due to gonadotroph ablation. Rather, the present data indicate that gonadotrophs directly stimulate the development of lactotrophs during fetal and early postnatal life, consistent with previous in vitro observations, and/or that gonadotrophs may share a cell-lineage relationship with a subpopulation of lactotrophs.

Shen, R., M. Sumitomo, et al. (2000). "Identification and characterization of two androgen response regions in the human neutral endopeptidase gene." Molecular and Cellular Endocrinology **170**(1-2): 131.

<http://www.sciencedirect.com/science/article/B6T3G-4233BNC-D/2/987a54374f43c51de959723e36a9e306>

Transcription of the human neutral endopeptidase 24.11 (NEP) gene is androgen regulated in prostate cancer cells. Homology search identified a sequence GTCACAagAGTTCT similar to the ARE consensus sequence GGTACAnnnTGTTCT within the 3'-untranslated region of the NEP mRNA. A double-stranded radiolabelled oligonucleotide containing this NEP-ARE sequence formed a DNA-protein complex with nuclear proteins from LNCaP cells or COS-7 cells co-transfected with an androgen receptor (AR) expression vector, and with full-length AR synthesized by baculovirus in mobility shift assays. Unlabeled NEP-ARE or consensus ARE but not mutated NEP-ARE replaced radiolabelled NEP-ARE. Steroid-dependent enhancement of transcription was assayed by transfecting ptkCAT reporter constructs containing the NEP-ARE into CV-1/AR cells and prostate cancer cells (PC-3/AR). Enhancement of chloramphenicol acetyltransferase (CAT) activity was increased four-fold by androgen, seven-fold by dexamethasone and three-fold by progesterone in CV-1/AR cells, and the NEP-ARE bound to glucocorticoid and progesterone receptor in mobility shift assays. We next performed DNase-I footprinting analysis of the NEP promoter and identified a 23 bp sequence GGTGCGGGTCGGAGGGATGCCCA (NEP-ARR) which was protected from DNase I cleavage by nuclear extracts from COS-7 cells expressing AR. This sequence was 62.5% homologous to an androgen responsive region (PSA-ARR) identified in the promoter of the prostate specific antigen (PSA) gene. A double-stranded radiolabelled oligonucleotide containing this NEP-ARR sequence formed DNA-protein complex with AR but not GR proteins. Unlabeled NEP-ARR, PSA-ARR and NEP-ARE replaced radiolabelled NEP-ARR. Steroid-dependent enhancement of transcription assays in PC-3/AR cells revealed that the enhancement of CAT activity was increased 2.3-fold by androgen, but not by glucocorticoid or progesterone. In a thymidine kinase promoter, the NEP-ARE and NEP-ARR together stimulated a five-fold increase in promoter activity in PC cells. These data suggest that steroid regulation of the NEP gene involves at least two elements including a typical ARE which binds androgen, progesterone and glucocorticoid receptors, and a unique ARR which only binds androgen receptor.

Shozu, M., Y. Zhao, et al. (2000). "TGF- β 1 stimulates expression of the aromatase (CYP19) gene in human osteoblast-like cells and THP-1 cells." Molecular and Cellular Endocrinology **160**(1-2): 123.

<http://www.sciencedirect.com/science/article/B6T3G-3YS34B7-G/2/c73ceae48348f8645e48ab656ada6b3c>

Recent evidence has shown that bone is not only a target of estrogen action but also a source of local estrogen production. Bone cells such as osteoblasts express aromatase (P450arom) and the expression of P450arom in osteoblasts is positively regulated in a tissue specific fashion, as in the case of other tissues which express P450arom. To clarify the physiological factors regulating expression of P450arom in bone, we tested TGF- β 1 using osteoblast-like cells obtained from human fetuses as well as THP-1 cells. TGF- β 1 increased IL-1 β +DEX-induced aromatase activity in osteoblast-like cells, while it inhibited activity in skin fibroblasts. Similar enhancement of aromatase activity by TGF- β 1 was found in DEX-stimulated THP-1 cells and this cell line was used for further experiments. In THP-1 cells, TGF- β 1 enhanced DEX-induced aromatase activity almost linearly by 12 h and thereafter. Increased levels of P450arom transcripts were also demonstrated by RT-PCR at 3 h of TGF- β 1 treatment and thereafter. Cyclohexamide abolished enhancement of activity but did not inhibit the accumulation of P450arom transcripts induced by TGF- β 1. Increase in P450arom expression by TGF- β 1 was attributable to expression driven by promoter I.4. TGF- β 1 did not change the half life of P450arom transcripts. To identify the cis-acting elements responsible for TGF- β 1 action on aromatase expression, transient transfection assays were performed using a series of deletion constructs for promoter I.4 (P450-I.4/Luc). Two constructs (-410/+14 and -340/+14) that contain a functional glucocorticoid response element (GRE) and downstream sequence showed significant increase of luciferase activity in response to TGF- β 1. Deletion and mutation of the GRE in P450-I.4/Luc (-340/+14) abolished the TGF- β 1. The luciferase activity of a (GRE)1-SV40/Luc construct was also stimulated by TGF- β 1. These results indicate that TGF- β 1 increases the expression of P450arom at the level of transcription through promoter I.4, at least in part via an enhancement of transactivation activity of the GR in THP-1 cells. TGF- β 1 is suggested to be one of the physiological up-regulatory factors of bone aromatase.

Simmen, R. C. M., L. Badinga, et al. (1993). "Chromosomal organization of the gene encoding porcine antileukoprotease and functional analysis of the promoter region in endometrial and placental cells." Molecular and Cellular Endocrinology **97**(1-2): 101.

<http://www.sciencedirect.com/science/article/B6T3G-47NWFBW-36/2/227a7e2ad7c8488900daff83269b999a>

The apparent preferential expression of the elastase/ cathepsin G protease inhibitor antileukoprotease (ALP) in endometrium of species with epitheliochorial placenta suggests mechanisms of transcriptional regulation unique to these mammalian species. To begin to define the cis-acting regulatory elements involved in the endometrial transcription of the ALP gene, the porcine ALP gene was isolated and characterized. The porcine gene spans at least 13 kb and consists of 5 exons and 4 introns. This genomic structure, except for an additional exon, is similar to that of the human gene where the first three exons encode the signal peptide, trypsin/ cathepsin G binding region, and elastase binding region, respectively. The positions of the 16 cysteine residues in exons 2 and 3 of the human gene are conserved in the porcine gene. The porcine gene contains a TATA box at -29 nucleotide (nt), and sequences with limited homology to those which might bind the transcription factors AP-1, AP-2, Sp-1 and Oct-1. The functional promoter activity of the ALP-5' flanking DNA was examined using chimeric ALP-chloramphenicol acetyl transferase (CAT) DNA constructs, after transient transfection in human (ECC-1, Ishikawa) and rabbit (HRE-H9) endometrial and human trophoblastic (JEG-3) cell lines. A 887 nt fragment of the ALP-5'-flanking region (- 887ALP-pCAT-E) was active in these cell lines, with the highest

promoter activity observed in the ECC-1. Progressive 5' deletion of the 887 nt fragment up to -243 nt had no effect on CAT gene expression in all cell lines, relative to the longest construct. Results suggest that the approximately 240 bp fragment most proximal to the transcription initiation site confers basal and limited endometrial tissue-specific promoter activity to the ALP gene 5'-flanking region. These studies also establish the ECC-1 cell line as an in vitro model system to elucidate the control of ALP gene transcription in the endometrium.

Too, C. K. L., A. Giles, et al. (1999). "Estrogen stimulates expression of adenine nucleotide translocator ANT1 messenger RNA in female rat hearts." Molecular and Cellular Endocrinology **150**(1-2): 161.

<http://www.sciencedirect.com/science/article/B6T3G-3WM5C4D-K/2/22aada3530f90294fd330c5ca1bd6bca>

The identification of estrogen-responsive genes in the heart, is necessary to understand estrogen-induced changes in cardiac function. Using Delta RNA fingerprinting, we demonstrate that a single injection of estradiol benzoate (50 [mu]g, s.c.) revealed mRNA species that were elevated, down-regulated, or were unaffected in the heart tissue of ovariectomized female rats. One of the upregulated genes was identified, by cloning and sequencing, to have 95.8% (230/240) identity with the 3' end of the rat ant1 gene encoding the mitochondrial adenine nucleotide translocator, ANT1. Using the isolated ANT1 cDNA (280 bp) as a probe in Northern analysis, estrogen was shown to upregulate the expression of cardiac ANT1, by at least 3-fold in female rats, from as early as 1 h to as long as 24 h. In contrast, estrogen treatment had no effect on ANT1 expression in heart tissue from male rats. RNA yields were low in rat atria and no transcript was detectable by Northern analysis. Using primers specific to the known rat ANT1 gene, the estrogen upregulation of the cardiac ANT1 transcript in female rat was confirmed by reverse transcriptase-polymerase chain reaction (RT-PCR); a predicted product of 249 bp was obtained and this was stimulated by at least 3-fold upon estrogen treatment for 24 h.

Vanden Broeck, J., D. Veelaert, et al. (1996). "Molecular cloning of the precursor cDNA for schistostatins, locust allatostatin-like peptides with myoinhibiting properties." Molecular and Cellular Endocrinology **122**(2): 191.

<http://www.sciencedirect.com/science/article/B6T3G-3W2T670-8/2/f3b0b8320e25c67f2af9fef23068a1b3>

The cDNA encoding the precursor polypeptide for schistostatins, allatostatin-like peptides which have been shown to inhibit peristaltic movements of the lateral oviducts of *Schistocerca gregaria*, has been cloned and sequenced. Translation of this sequence reveals the presence of a pre-proschistostatin consisting of 283 amino acids. It contains ten different peptide sequences which are flanked by dibasic cleavage sites and C-terminal amidation signals. Eight of these peptides were identical to the schistostatins (or Scg-ASTs) that were previously purified from *Schistocerca gregaria* brain extracts. Two novel peptide sequences were discovered. One of these is the first AST-like peptide which has a C-terminal valine residue. Two peptides contain within their sequence an internal dibasic site which suggests a possible role for alternative processing and/or degradation. The schistostatin precursor differs from cockroach pre-proallatostatins in size, in sequence and in organization. It contains a lower number of peptides (10 versus 13 or 14) which are interrupted only once by an acidic spacer region (versus four in *Diploptera punctata* and *Periplaneta americana*). Northern analysis showed the presence of a 2.4 kb mRNA band in the locust central nervous system and midgut. This indicates that schistostatins, like other ASTs, are a good example of insect brain/gut peptides.

VanderHeyden, T. C., P. W. Wojtkiewicz, et al. (2000). "Mouse growth hormone transcription factor Zn-16: unique bipartite structure containing tandemly repeated zinc finger domains not reported in rat Zn-15." Molecular and Cellular Endocrinology **159**(1-2): 89.

<http://www.sciencedirect.com/science/article/B6T3G-3YDGFYR-B/2/330897c3548224195b3e394d5828b522>

Rat Zn-15 is a transcription factor activating GH gene expression by synergistic interactions with Pit-1, named for 15 DNA-binding zinc fingers, including fingers IX, X, and XI that are responsible for GH promoter binding. In this study, a mouse cDNA for Zn-15 was characterized. The predicted 2192-amino acid mouse protein is 89% identical to rat (r) Zn-15 overall, and is 97% similar in the C-terminal domain necessary for binding the GH promoter. However, the mouse cDNA encodes 16 zinc fingers, and sequences of rZn-15 pituitary cDNAs were the same as the mouse (m) Zn-16; the rat sequence in GenBank has a one nucleotide offset of a 17-bp segment in the finger V region. The mouse and corrected rat sequences contain four tandemly repeated fingers in the N-terminus, each separated by seven amino acids, typical of zinc finger proteins of the transcription factor IIIA-type. Analysis of mZn-16 expression by RT-PCR showed that the mRNA is produced at similar levels in normal and GH-deficient Ames dwarf (Prop-1) mouse pituitaries at postnatal day 1. Mouse Zn-16 mRNA also was detected by ribonuclease protection assay in the pre-somatotrophic mouse cell line GHFT1-5. The Zn-16 protein is bipartite in that the N-terminal half displays tandem spacing typical of most zinc finger proteins, while the C-terminal portion contains long linkers between fingers that cooperatively bind to a DNA response element. Expression in early postnatal pituitary and in pre-somatotrophic cells suggests that Zn-16 could play a role in pituitary development prior to somatotroph differentiation.

Voss, T. C., L. R. Goldman, et al. (2001). "GH mRNA levels are elevated by forskolin but not GH releasing hormone in GHRH receptor-expressing MtT/S somatotroph cell line." Molecular and Cellular Endocrinology **172**(1-2): 125.

<http://www.sciencedirect.com/science/article/B6T3G-427JWGY-1J/2/9d484055d765d2d8608e80386ceb5204>

The MtT/S somatotroph cell line should be a growth hormone-releasing hormone (GHRH)-responsive model system for the study of physiological control of growth hormone (GH) transcription because GH secretion from these cells is stimulated by GHRH. To examine the GH transcriptional activity of these cells, endogenous GH mRNA levels were measured using a ribonuclease protection assay following treatment under a variety of hormonal conditions. While omission of serum led to reduction of GH mRNA to 22% of control levels by 2 days and to 8% by 5 days ($P=20$ nmol/106 cells per h in both serum-containing and serum-free media, and that GHRH had no effect on cAMP levels, suggesting constitutive activation. To rule out the possibility of autocrine stimulation by GHRH produced endogenously, GHRH mRNA was not detectable in MtT/S cells using RT-PCR amplification. The stimulatory G-protein [α] subunit, mutations of which are known to activate adenylate cyclase constitutively in acromegaly, was sequenced but found not to differ from normal pituitary in the regions most commonly mutated. Finally, treatment with 10 [μ]M forskolin, to directly activate adenylate cyclase, increased GH mRNA to 140% of controls in TDM, and to 163% in serum-free medium after 2 days, and to 166% in TDM-treated cells and 174% in serum-free culture after 5 days (all Pgps mutations).

Wang, L., L.-P. Xie, et al. (2001). "Presence of gonadotropin-releasing hormone (GnRH) and its mRNA in

rat pancreas." Molecular and Cellular Endocrinology **172**(1-2): 185.

<http://www.sciencedirect.com/science/article/B6T3G-427JWGY-1S/2/519d326fb21fe9999bd1c0b76558bf34>

Gonadotropin-releasing hormone (GnRH) has been reported to exist in many non-hypothalamic tissues, such as the placenta, gonads, and mammary glands, while there still have been no reports concerning the existence and expression of GnRH in the mammalian digestive system. Immunocytochemistry and in situ hybridization results show that GnRH molecule and GnRH mRNA are both exclusively distributed in exocrine pancreas, and RT-PCR result further proves that GnRH transcription units do exist in the pancreas, which possess the same sequence as the hypothalamus GnRH mRNA. Quantitative analysis indicates that mRNA levels in rat pancreas remain at a low level (less than 10% of that in hypothalamus) without sexual or developmental difference. This is the first report suggesting the existence and gene expression of GnRH in rat pancreas.

Williams, C. P., C. Postic, et al. (1999). "Isolation and characterization of the mouse cytosolic phosphoenolpyruvate carboxykinase (GTP) gene: evidence for tissue-specific hypersensitive sites." Molecular and Cellular Endocrinology **148**(1-2): 67.

<http://www.sciencedirect.com/science/article/B6T3G-3VTYSMT-8/2/2ff88846b64c32c7b4ea8f1b33f27131>

A 72 kilobase pair DNA fragment that contains the mouse phosphoenolpyruvate carboxykinase (PEPCK) gene locus, pck1, was isolated from a genomic bacterial artificial chromosome library. The region from ~-5.5 to +6.6 kilobase pairs relative to the pck1 transcription start site was sequenced and exhibits a high degree of homology to the rat and human genes. Additionally, the chromatin structure of the PEPCK gene in mouse liver resembles that seen in rat. Backcross panel analysis of a microsatellite sequence confirms that the gene is located on chromosome 2. Hypersensitive site analysis was performed on nuclei isolated from the adipocyte cell line 3T3-F442A in the preadipose and adipose states. Several hypersensitive sites are present in the undifferentiated 3T3-F442A cells, before PEPCK mRNA is detected. The same sites are present after differentiation, however, the sensitivity of mHS 3 increases relative to the others. We conclude that the chromatin is open in 3T3-F442A cells and that factors are able to bind in the undifferentiated state but that something else is required for transcription.

Yarney, T. A., M. R. Sairam, et al. (1993). "Molecular cloning and expression of the ovine testicular follicle stimulating hormone receptor." Molecular and Cellular Endocrinology **93**(2): 219.

<http://www.sciencedirect.com/science/article/B6T3G-47N6MJR-JG/2/832005b95edd318dd058231bf964f9f1>

A sheep testicular cDNA library constructed in pcDNA1 vector was screened with a probe generated by polymerase chain reaction (PCR) and corresponding to a 1.6 kb fragment of the rat luteinizing hormone receptor cDNA. Several clones hybridizing to the rat probe at low stringency were sequenced to obtain 95% of the putative full-length ovine follicle-stimulating hormone receptor (oFSH-R) cDNA. The missing 5' region was obtained by PCR amplification of the cDNA library. Sequencing revealed a 2085 nucleotide open reading frame encoding a mature protein of 678 amino acids (74,580 daltons). The oFSH-R is remarkably similar (> 90%) to the human and rat FSH receptors, has a structural motif like the G protein-coupled family of receptors and contains 3 potential sites for N-linked glycosylation. RNA blot analysis revealed two major

transcripts of 2.6 kb and 6.7 kb in size and a smaller transcript of about 1 kb in the sheep testis. A 53 residue segment in the extracellular domain unique to the receptor contains more than 50% of residues bearing functional side chains that could participate in ligand (FSH) interaction and/or signal transduction. Transfection of human fetal kidney cell line (293) with the cloned oFSH receptor cDNA based in pcDNA1/Neo vector revealed functional expression. Labeled oFSH bound to receptor expressed on the membrane with high affinity and specificity. In stably transfected 293 cells, purified oFSH and hFSH but not oLH stimulated cyclic AMP accumulation. Chemically deglycosylated oFSH (DG-oFSH) was inactive in these cells but it effectively blocked the action of native hormone. Thus, the functional characteristics of the cloned receptor are similar to the natural receptor in testis.

Molecular and Cellular Neuroscience (7)

Gurney, M. E. and H. Yamamoto (1991). "Expression of recombinant rat ciliary neurotrophic factor in *Escherichia coli* and its synergy with basic fibroblast growth factor." Molecular and Cellular Neuroscience **2**(5): 369.

<http://www.sciencedirect.com/science/article/B6WNB-4F0PTB1-W/2/e5b7a9e88d3fd9ce8bc79b9fc48ffbf>

Rat CNTF was expressed in *Escherichia coli* using a T7 RNA polymerase vector system. rCNTF was obtained as an insoluble aggregate at levels approaching 70% of total *E. coli* protein. After extraction, renaturation, and purification by anion-exchange chromatography and gel filtration the yield of biologically active rCNTF was nearly 0.5 mg/ml of *E. coli* culture broth. The effects of rCNTF and bFGF on cultured chick ciliary neurons were compared. bFGF was primarily neuritogenic and did not support ciliary neuron survival beyond 2 days in culture. rCNTF induced neuritogenesis more slowly and supported ciliary neuron survival in culture for a longer period. bFGF strongly potentiated the effect of rCNTF. Without bFGF, the ED50 for rCNTF was 102 +/- 25 pg/ml. With bFGF, the potency of rCNTF increased to an ED50 of 42 +/- 6 pg/ml. Chick nodose neurons also responded to rCNTF and their response was potentiated by bFGF. Thus, bFGF modulates the response of ciliary and nodose neurons to CNTF in vitro and may have a similar effect in vivo.

Juryne, M. J., C. P. Riley, et al. (2003). "TIGR is upregulated in the chronic glial scar in response to central nervous system injury and inhibits neurite outgrowth." Molecular and Cellular Neuroscience **23**(1): 69.

<http://www.sciencedirect.com/science/article/B6WNB-48FK4SW-7/2/39ba92863fa0ad23b241cef2152eaf6b>

Reactive astrocytes respond to central nervous system (CNS) injury and disease by elaborating a glial scar that is inhibitory to axonal regeneration. To identify genes that may be involved in the astrocytic response to injury, we used differential display polymerase chain reaction and an in vivo model of the CNS glial scar. Expression of the trabecular meshwork inducible glucocorticoid response (TIGR) gene was increased in gliotic tissue compared with the uninjured cerebral cortex. Increased TIGR expression by reactive astrocytes was confirmed by in situ hybridization, quantitative reverse transcriptase-polymerase chain reaction, immunoblot analysis, and

immunohistochemistry. Although mutations of the TIGR gene have been implicated in glaucoma, a function for TIGR has not been reported. Since TIGR is secreted, we assessed a possible role in inhibition of neuronal regeneration with an in vitro bioassay and found that this protein is a potent inhibitor of neurite outgrowth. Thus, TIGR is a newly identified component of the CNS glial scar that is likely to contribute to neuronal regenerative failure characteristic of the mammalian CNS.

Kury, P., H. Koller, et al. (2003). "Cyclic AMP and tumor necrosis factor-[alpha] regulate CXCR4 gene expression in Schwann cells." Molecular and Cellular Neuroscience **24**(1): 1.

<http://www.sciencedirect.com/science/article/B6WNB-48PVDG8-N/2/6234126ecff62831690858a7dc289d96>

Rat peripheral nerve Schwann cells have been shown to express the [alpha]-chemokine receptor CXCR4 as well as the corresponding ligand stromal cell-derived factor-1 (SDF-1). We have investigated gene regulatory mechanisms acting on the expression of CXCR4 in cultured rat Schwann cells and found that receptor expression at transcript- and protein levels is directly dependent on intracellular cyclic AMP. Such increased levels of CXCR4 expression were found to be efficiently reversed by the action of tumor necrosis factor-[alpha] (TNF[alpha]). We also provide evidence that the POU box transcription factor Oct-6/SCIP is involved in the control of CXCR4 transcription. Finally, we could demonstrate that CXCR4 activation by SDF-1[alpha] increases the number of dying Schwann cells, indicating that this receptor/ligand interaction is modulating cell survival. Our data, therefore, suggest that in the Schwann cell lineage signal transduction cascades controlled by the activation of TNF- and CXCR4 receptors are functionally coupled.

Kusy, S., L. Funkelstein, et al. (2003). "Redundant functions but temporal and regional regulation of two alternatively spliced isoforms of Semaphorin 3F in the nervous system." Molecular and Cellular Neuroscience **24**(2): 409.

<http://www.sciencedirect.com/science/article/B6WNB-496NKDJ-6/2/cb8e3b6dcf762646fc5db398bf100479>

SEMA3F is a secreted semaphorin that affects axon and cell guidance in the developing nervous system, and is also thought to have anti-tumor activity. Two spliced forms of SEMA3F have been identified that differ by the insertion of 31 amino acids in the sema domain. Here, we investigated the bioactivity of these isoforms and show, using coculture and binding assays, that they share common axonal chemorepulsive properties and binding to neuropilin receptors. SEMA3F isoforms were also found to regulate endothelial cell morphology by remodeling lamellipodial protrusions. Although Sema3F expression globally decreased during mouse development, we noted an enrichment of the longest isoform at postnatal stages in some territories such as the brainstem and spinal cord. These results indicate that although functionally redundant in cell culture assays, Sema3F spliced forms are characterized in vivo by a temporal and regional specific regulation during maturation of the nervous system.

Sikela, J. M., N. J. Leidenheimer, et al. (1991). "Localization and functional expression of alternatively spliced forms of the GABAA receptor [gamma]2 subunit." Molecular and Cellular Neuroscience **2**(4): 338.

<http://www.sciencedirect.com/science/article/B6WNB-4DYM8XC-9/2/bbad97d573982c1a78e06b591989b2ca>

Recent studies have identified two alternatively spliced forms of the GABAA receptor [gamma]2 subunit that differ by the presence ([gamma]2L) or absence ([gamma]2S) of an eight-amino acid segment. This insert in the [gamma]2L isoform exists in the proposed cytoplasmic loop region, between M3 and M4, and contains a consensus sequence for phosphorylation by protein kinase C. To examine the regional distribution of this novel receptor subunit in the brain, [gamma]2L subunit mRNA was detected using both in situ hybridization histochemistry and PCR amplification methods. Hybridization histochemistry with a [gamma]2L, subunit-specific oligonucleotide probe revealed that the [gamma]2L, subunit mRNA is widely distributed throughout the mouse brain. The highest levels of expression are found in the cerebral cortex, hippocampus, olfactory lobe, and cerebellum. The presence of the [gamma]2L, subunit in these regions was confirmed using PCR. Additionally, PCR experiments detected yes subunit mRNA in the cerebral cortex and hippocampus but not in the cerebellum. To examine the functional properties of the [gamma]2 subunit isoforms, [gamma]2S and [gamma]2L, subunit mRNAs were coexpressed with [alpha]1[beta]1 subunit mRNAs in *Xenopus* oocytes. These experiments indicate that the [gamma]2L and [gamma]2S subunit variants exhibit similar pharmacological properties, including the ability of both isoforms to confer diazepam sensitivity to the receptor complex. In addition, potentiation of GABA responses by pentobarbital in oocytes expressing either subunit isoform is similar. These data indicate that the presence or absence of the additional eight amino acids in the [gamma]2 subunit isoforms does not appear to alter the response of the GABAA receptor complex to either benzodiazepines and barbiturates at the level of protein phosphorylation present in the oocyte.

Tortarolo, M., P. Veglianesi, et al. (2003). "Persistent activation of p38 mitogen-activated protein kinase in a mouse model of familial amyotrophic lateral sclerosis correlates with disease progression." Molecular and Cellular Neuroscience **23**(2): 180.

<http://www.sciencedirect.com/science/article/B6WNB-48FK4SW-1/2/e9eed170a04bd49b549f60c56a56a301>

The p38 mitogen-activated protein kinase (p38MAPK) is activated via phosphorylation in neurones and glial cells by a variety of stimuli including oxidative stress, excitotoxicity, and inflammatory cytokines. Activated p38MAPK can in turn induce phosphorylation of cytoskeletal proteins and activation of cytokines and nitric oxide, thus contributing to neurodegeneration. We investigated the expression and distribution of p38MAPK in the spinal cord of transgenic mice expressing a superoxide dismutase 1 mutation (SOD1G93A), a model of familial amyotrophic lateral sclerosis (ALS). Accumulation of p38MAPK was found by immunoblotting in the spinal cord of G93A mice during the progression of disease, but no changes were detected in its mRNA levels. Immunostaining for phosphorylated p38MAPK in lumbar spinal cord sections of SOD1G93A mice at the presymptomatic and early stages of disease showed an increased labeling in motor neurones that colocalized with phosphorylated neurofilaments in vacuolized perikarya and neurites, as detected by confocal microscopy. As the disease progressed, activated p38MAPK also accumulated in hypertrophic astrocytes and reactive microglia, as demonstrated by colocalization with GFAP and CD11b immunostaining, respectively. These data suggest that activation of p38MAPK in motor neurones and then in reactive glial cells may contribute, respectively, to the development and progression of motor neuron pathology in SOD1G93A mice.

Zaratin, P. F., A. Quattrini, et al. (2005). "Schwann cell overexpression of the GPR7 receptor in inflammatory and painful neuropathies." Molecular and Cellular Neuroscience **28**(1): 55.

<http://www.sciencedirect.com/science/article/B6WNB-4DXB9YN-1/2/3462dade0b819d5de0299a9b73992ba2>

The human 7-transmembrane receptor GPR7 has sequence similarity to opioid and somatostatin receptors, and can be activated by the recently discovered neuropeptides NPB and NPW. This receptor is highly expressed in the nervous system, with suggested roles in neuroendocrine events and pain signaling. In this study, we investigated whether the GPR7 receptor is expressed in the peripheral nervous system under normal and pathological conditions. A low level of GPR7 receptor was observed in myelin-forming Schwann cells in both normal human and rat nerve, and in primary rat Schwann cell cultures. Peripheral nerve samples taken from patients exhibiting inflammatory/immune-mediated neuropathies showed a dramatic increase of GPR7 receptor expression restricted to myelin-forming Schwann cells. Complementary animal models of immune-inflammatory and ligation-induced nerve injury and neuropathic pain similarly exhibited an increased myelin-associated expression of GPR7 receptor. These results suggest a relationship between the pathogenesis of inflammatory/immune-mediated neuropathies, GPR7 receptor expression, and pain transmission.

Molecular and Cellular Probes(38)

Ahmad, S., E. Mokaddas, et al. (2004). "Rapid detection of ethambutol-resistant Mycobacterium tuberculosis strains by PCR-RFLP targeting embB codons 306 and 497 and iniA codon 501 mutations." Molecular and Cellular Probes **18**(5): 299.

<http://www.sciencedirect.com/science/article/B6WNC-4CHRGDY-1/2/0fc1a263987e61e7c08ada24452448da>

Mutations at embB gene codons 306 and 497 and iniA gene codon 501 occur frequently in ethambutol (EMB)-resistant Mycobacterium tuberculosis strains worldwide. The identification of these mutations in resistant strains has been achieved by labor-intensive DNA sequencing or by tedious amplification protocols followed by restriction endonuclease digestion. In this report, we describe PCR-restriction fragment length polymorphism (RFLP)-based methods for determining substitutions at embB codons 306 and 497 and iniA codon 501 directly in BACTEC cultures of M. tuberculosis isolates. The wild-type and mutant alleles are revealed by easily interpretable and different RFLP patterns. The methods optimized initially on reference strains were tested directly on BACTEC cultures of 25 randomly selected clinical M. tuberculosis isolates, seven of which were determined to contain EMB-resistant strains by phenotypic drug susceptibility testing. The PCR-RFLP methods identified mutations in four of seven EMB-resistant strains with three isolates containing mutated embB codon 306 and one isolate containing mutated embB codon 497. The results of PCR-RFLP were confirmed by DNA sequencing. The worldwide prevalence figures for mutations at embB codons 306 and 497 and iniA codon 501 suggest that nearly half of EMB-resistant M. tuberculosis strains could be identified within one working day even in developing countries equipped with simple PCR technology instead of weeks required for phenotypic drug susceptibility testing. Further, since EMB resistance is also associated with multiple-drug resistance from some geographical locations, detection of EMB resistance may also lead to rapid identification of multidrug-resistant strains of M. tuberculosis.

An, S. F., D. Franklin, et al. (1992). "Generation of digoxigenin-labelled double-stranded and single-

stranded probes using the polymerase chain reaction." Molecular and Cellular Probes **6**(3): 193.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-30/2/5e63dbdc394136ce873a50ed261eedb>

As the polymerase chain reaction (PCR) can be used for the generation of vector-free probes, the optimum conditions for incorporation of digoxigenin-11-dUTP into hepatitis B virus (HBV) probes have been investigated. High yields of double-stranded or single-stranded probes can be obtained by utilizing a pair of primers or one primer alone. The probes were tested by dot-blot hybridization on HBV plasmid DNA, slot-blot hybridization on total cellular RNA of Alexander cells and Southern blot hybridization on cellular DNA of Alexander cells and HBV plasmid DNA. They were also tested by in situ hybridization (ISH) on HBV-positive biopsy liver tissue. A ratio of dig-dUTP:dTTP of 1:3 gave highest sensitivity in DNA hybridization. No loss of amplification efficiency and sensitivity was observed when the final concentration of dig-11-dUTP and dTTP was reduced to 20 [mu]M and 60 [mu]m respectively, compared to 200 [mu]m each of dATP, dCTP, dGTP. Several different sizes of double-strand probes were compared by dot-blot hybridization. Longer probes were more sensitive. Strong signal could also be obtained by combination of two or three small probes, which have overlapping sequences. Single-stranded DNA probes had advantages of simplicity of use, high sensitivity and strand specificity.

Bobba, A., E. Marra, et al. (2003). "Non-radioactive detection of five common microsatellite markers for ATP7B gene in Wilson disease patients." Molecular and Cellular Probes **17**(6): 271.

<http://www.sciencedirect.com/science/article/B6WNC-49HSTV6-1/2/feb91b218644ec50acae01df1aa9a62e>

Haplotype analysis using microsatellite markers is a useful indicator of specific mutations and is often exploited as the first large-scale screening technique to carry out the molecular characterization of the disease gene in probands from a specific population. However, the methodologies available are still cumbersome and require the use of either radioactive compounds or specialized equipment suitable to follow fluorescent dyes. Both these techniques may not be available for newly developing clinical laboratories. We have set up a sensitive and easy-to-use protocol to characterize five closely spaced, highly polymorphic microsatellite polymorphisms (CA repeats) that span the Wilson disease (WD) region, i.e. D13S316, D13S133, D13S301, D13S314, D13S315. The technique described here for the analysis of the WD gene microsatellite system relies on the quick detection method of silver staining, avoiding the use of toxic or sophisticated equipment. This approach could be the method of choice to implement molecular genetic testing in clinical laboratories, even those not especially equipped for DNA analysis and in particular in newly developed molecular genetics centers in countries whose population has not yet been characterized for WD-causing ATP7B gene mutations.

Bottero, M. T., A. Dalmaso, et al. (2004). "Development of a multiplex PCR assay for the identification of pathogenic genes of Escherichia coli in milk and milk products." Molecular and Cellular Probes **18**(4): 283.

<http://www.sciencedirect.com/science/article/B6WNC-4CB0HNX-1/2/47788539570c45d133bf7f2ac2ed128a>

A multiplex PCR for the simultaneous detection of some pathogenic genes of enteropathogenic, enterotoxigenic and verocytotoxin-producing Escherichia coli was developed. In this study primers found in literature as well as primers to the purpose designed were used. In this way, it was

possible to generate specific fragments of 96, 170, 229, 285, 348, 414 and 510 bp for Hly_A, St, EaeA, Lt, Vt1, UidA and Vt2 genes, respectively. When applied to bacterial strains experimentally inoculated in milk and milk products, the proposed PCR showed a detection limit of 5 x 10⁴ CFU/ml for Hly_A, St, EaeA, Vt1 primers, while for Lt and Vt2 primers the limit resulted of 10⁶ CFU/ml.

Brogan, J. M., J. Acciai, et al. (1992). "Development of a DNA probe for *Ureaplasma urealyticum*." Molecular and Cellular Probes **6**(5): 411.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-2F/2/331343dc3f5c815d3f106a7aec237c7>

Ureaplasma urealyticum has been associated with a variety of disease conditions in humans. However, its exact etiologic role has not been well established because of the difficulties encountered in cultural diagnosis and the time needed for positive identifications. A DNA probe which is specific for a target DNA sequence unique to this suspected pathogen offers a rapid, sensitive and specific means of diagnosis. This study details the development of a polymerase chain reaction system for *U. urealyticum*. Using conventional hybridization techniques, a cloned genomic fragment was found to be specific for this organism. Sequencing of part of this probe DNA permitted the assignment of oligonucleotide primers which amplified a 186 bp target segment. This PCR system is specific for *U. urealyticum* but not for other closely related species of mycoplasma. This highly sensitive diagnostic technique will aid in determining the etiologic role, tissue tropism and dynamics of pathogenesis of this organism, and thereby result in better patient care.

Carlson, S. A. and M. T. Wu (2003). "Avoidance of false PCR results with the integron-retron junction in multiple antibiotic resistant *Salmonella enterica* serotype Typhimurium." Molecular and Cellular Probes **17**(4): 183.

<http://www.sciencedirect.com/science/article/B6WNC-4938M0C-1/2/923b86c6e539907e236960ab9970126e>

Salmonella infections continue to cause gastrointestinal and systemic disease throughout the world. Another concern with this pathogen is the ability to acquire integrons that confer resistance to multiple antibiotics. For multiresistant *Salmonella enterica* serotype Typhimurium, the most common multiresistant *Salmonella* serotype, an integron structure can be found between *thdF* and a retron. Our objective was to investigate the utility of a 450 bp *thdF*-retron amplicon as an indicator of an insertless *thdF*-retron junction thus indicating an integron-free strain. Surprisingly, we found that the 450 bp *thdF*-retron amplicon was present, and thus incorrectly suggesting an integron-free status, in some multiresistant *S. enterica* serotype Typhimurium isolates. However, this phenomenon was not observed if the isolate was enriched in the presence of two antibiotics. This demonstrates that, within some individual clinical isolates of multiresistant *S. enterica* serotype Typhimurium, there exists a small subpopulation of integron-free bacteria. Consequently, it appears that the *thdF*-retron amplicon is an inaccurate predictor of integron status in *S. enterica* serotype Typhimurium unless multiresistance is used as a selection tool during enrichment.

Caterina, K. M., J. S. Frasca, et al. (2004). "Development of a multiplex PCR for detection of avian adenovirus, avian reovirus, infectious bursal disease virus, and chicken anemia virus." Molecular

and Cellular Probes **18**(5): 293.

<http://www.sciencedirect.com/science/article/B6WNC-4CHRGDY-2/2/5f78e57c627066509a23c40245c79db5>

A multiplex polymerase chain reaction (mPCR) was developed and optimized for the simultaneous detection and differentiation of avian reovirus (ARV), avian adenovirus group I (AAV-I), infectious bursal disease virus (IBDV), and chicken anemia virus (CAV). Four sets of specific oligonucleotide primers were used in this test for ARV, AAV-I, IBDV, and CAV. The mPCR DNA products were visualized by gel electrophoresis and consisted of fragments of 365 bp for IBDV, 421 bp for AAV-I, 532 bp for ARV, and 676 bp for CAV. The mPCR assay developed in this study was found to be sensitive and specific. Detection of PCR-amplified DNA products was 100 pg for both CAV and IBDV, and 10 pg for both ARV and AAV-I and this mPCR did not amplify nucleic acids from the other avian pathogens tested. The mPCR demonstrated similar sensitivity in tests using experimental fecal cloacal swab specimens that were spiked with ARV, AAV-I, IBDV, and CAV, and taken from specific pathogen free (SPF) chickens. This mPCR detected and differentiated various combinations of RNA/DNA templates from ARV, AAV-I, CAV, and IBDV without reduction of amplification from feces.

Cuppens, H., I. Buyse, et al. (1992). "Simultaneous screening for 11 mutations in the cystic fibrosis transmembrane conductance regulator gene by multiplex amplification and reverse dot-blot." Molecular and Cellular Probes **6**(1): 33.

<http://www.sciencedirect.com/science/article/B6WNC-4DYVPKN-2P/2/b5d61e28b1c93341d2dbe43abc6cc142>

An assay is described in which 11 mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene can be screened simultaneously. Six different exons of the CFTR gene are amplified in a single multiplex amplification. Biotinylated dUTP is incorporated into the different fragments during the amplification process. A sample of this mixture is then hybridized to 21 different poly-dT tailed oligonucleotide probes which are bound to a nylon membrane. In order to screen the different mutations in a single step hybridization, the length of the different oligonucleotides and the amount used in the assay were optimized. The detection is performed by binding avidin-alkaline phosphatase to the biotin, followed by a chemiluminescent reaction. By means of this fast and sensitive assay, about 85% of all the cystic fibrosis mutations in the Belgian population can be detected.

Exner, M. M. and M. A. Lewinski (2002). "Sensitivity of multiplex real-time PCR reactions, using the LightCycler and the ABI PRISM 7700 Sequence Detection System, is dependent on the concentration of the DNA polymerase." Molecular and Cellular Probes **16**(5): 351.

<http://www.sciencedirect.com/science/article/B6WNC-47CJ5D5-5/2/1ab695694b42544a7b3da1e86006035b>

The introduction of multiplex PCR techniques to clinical laboratories has provided a means to streamline assays and to produce multiple results with minimal effort. While this methodology is very beneficial, care must be taken to ensure that reactions are properly optimized to allow for maximum sensitivity. This study was conducted to determine whether the sensitivity of multiplex-real-time PCR assays could be improved by increasing the concentration of DNA polymerase within a reaction. Multiplex reactions were designed to simultaneously detect the human HLA-DQ gene and a sequence from the UL83 region of the CMV genome. Two real-time PCR systems,

one utilizing AmpliTaq Gold DNA polymerase and the ABI 7700 Sequence Detection System, and one utilizing FastStart Taq DNA polymerase and the Roche LightCycler were tested. The results indicated that increasing the AmpliTaq Gold concentration from 0.050 to 0.10 U/[μ] and the FastStart Taq concentration from 0.1875 to 0.375 U/[μ] increased detection sensitivity from 5000 to 50 CMV copies per PCR reaction. In separate experiments, commercially prepared mastermixes were utilized for both real-time PCR platforms as per the manufacturer's suggestions or with the addition of supplemental DNA polymerase. In assays designed to detect 4 CMV genome copies per reaction, the addition of 2.5 U of AmpliTaq Gold to TaqMan Universal Mastermix increased the detection rate from 21 to 67%, and the addition of 5 U of FastStart Taq to FastStart DNA Master Hybridization Probes mastermix increased the detection rate from 17 to 56%. These results indicate that increasing the DNA polymerase concentration in multiplex real-time PCR reactions may be a simple way to optimize assay sensitivity.

Fortina, P., R. Conant, et al. (1992). "Fluorescence-based, multiplex allele-specific PCR (MASPCR) detection of the [Δ]F508 deletion in the cystic fibrosis transmembrane conductance regulator (CFTR) gene." Molecular and Cellular Probes 6(4): 353.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-F/2/12122f842c21a790567637d58adfbce2>

Cystic fibrosis (CF) is a common genetic disorder in Caucasians, and in some populations 70% of cases are associated with a 3 base pair (bp) deletion ([Δ]F508) in the CFTR gene. We have implemented a fluorescence-based, multiplex allele-specific polymerase chain reaction (MASPCR) assay for deletion of the [Δ]F508 mutation. Different allele-specific fluorescently-tagged primers are used in the PCR reaction to distinguish between normal and [Δ]F508 alleles. Fluorescent PCR products are then visualized in a single lane on an agarose gel following electrophoresis combined with real-time multicolour fluorescence detection. The approach simplifies diagnosis of the most common mutation in the CFTR gene, and holds promise for a multiplex allele-specific, fluorescence-tagged gene amplification strategy for detection of additional CF mutations which may result in more cost-effective testing without increasing the risk of missed or erroneous diagnoses.

Gage, K. L., R. D. Gilmore, et al. (1992). "Detection of *Rickettsia rickettsii* in saliva, hemolymph and triturated tissues of infected *Dermacentor andersoni* ticks by polymerase chain reaction." Molecular and Cellular Probes 6(4): 333.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-B/2/735a4fcf32c5bebada99ad3560beff4b>

The technique of polymerase chain reaction (PCR) is potentially superior to existing methods for detecting rickettsial infections in ticks. For this reason, we developed assays for identifying rickettsial infections in ticks by PCR. Our assays amplified a 500 bp fragment from the gene encoding the rOmp B protein of *Rickettsia rickettsii*. The selected primers amplified fragments of the predicted size from all spotted fever group rickettsiae (*R. rickettsii*, *R. parkeri*, *R. conorii*, *R. sibirica*) tested. No amplified products were detected when typhus group rickettsiae (*R. canadensis*, *R. prowazekii*, *R. typhi*) were assayed. Using techniques described in this study, we reliably amplified the predicted product from hemolymph, saliva and ground leg tissue samples from live, partially fed, infected ticks. Samples derived from infected ticks preserved in 70% ethanol also were suitable for amplification by PCR. Similar assays performed with infected ticks preserved in 5% buffered formalin seldom gave positive results.

Gharizadeh, B., A. Ohlin, et al. (2003). "Multiple group-specific sequencing primers for reliable and rapid DNA sequencing." Molecular and Cellular Probes **17**(4): 203.

<http://www.sciencedirect.com/science/article/B6WNC-497HB05-1/2/01f0c767037ce348564946e0a6f8f100>

Pyrosequencing(TM) technology is a bioluminometric DNA sequencing method that employs a cascade of four enzymes to deliver sequence signals. To date this technology has been limited to the sequencing of short stretches of DNA. As an improvement to this technique, we have introduced a bacterial group-specific, multiple sequencing primer approach that circumvents sequencing of less informative semi-conservative regions of the 16S rRNA gene. This new approach is suitable for challenging templates, improving sequence data quality, avoiding sequencing of non-specific amplification products, lessening sequencing time, and moreover, this strategy should open the way for many new applications in the future. The group-specific, multiple sequencing primers can be applied in the Sanger dideoxy sequencing method as well. In addition, we have improved the chemistry of the Pyrosequencing system enabling sequencing of longer stretches of DNA, which allows numerous new applications.

Gilbert, C., D. Winters, et al. (2003). "Development of a triplex PCR assay for the specific detection of *Campylobacter jejuni*, *Salmonella* spp., and *Escherichia coli* O157:H7." Molecular and Cellular Probes **17**(4): 135.

<http://www.sciencedirect.com/science/article/B6WNC-48WPS6K-1/2/070daa389f7f3cd9496e4e9bf1fba7b8>

A triplex PCR assay was developed and evaluated for efficacy in detecting *Campylobacter jejuni*, *Salmonella* spp., and *Escherichia coli* O157:H7 in a variety of raw and ready-to-eat food products. Following a short enrichment period, artificially contaminated food samples were subjected to a triplex PCR assay, which incorporated published primers for each food pathogen, a protocol for sample collection, and a PCR procedure designed specifically for the assay. The selected primers amplified fragment sizes of 159 bp, 252 bp, and 360 bp for *C. jejuni*, *E. coli* O157:H7, and *Salmonella* spp., respectively. This assay provides specific and reliable results and allows for the cost-effective detection of all three bacterial pathogens in one reaction tube.

Gravitt, P., A. Hakenewerth, et al. (1991). "A direct comparison of methods proposed for use in widespread screening of human papillomavirus infections." Molecular and Cellular Probes **5**(1): 65.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-1P/2/a825a684ec55eacfb930e247364e6369>

We obtained cervical swabs from 397 women participating in a human papillomavirus (HPV) prevalence study. Samples were assayed for HPV infection using ViraPap expanded cocktail (detecting HPV types 6, 11, 16, 18, 31, 33, 35, 42, 43, 44, 45, 51, 52 and 56), ViraType and PCR amplifications. Consensus primers from the L1 region were used with generic and type-specific oligonucleotide probes. Additionally, the generic amplifications were analysed with a novel restriction digest scheme. Samples positive by these methods were confirmed by PCR amplification using primers from the E5 region specific for HPV types 6, 16 and 18. The presence of human DNA in the samples was verified with amplification of the human KM-19 haplotyping

primers. Our results confirm that the PCR reporter oligomer hybridization method is more sensitive than ViraPap/ViraType, but encompasses a narrower range of HPV types. This is particularly true of the higher number types in the expanded cocktail. The narrow range seems to occur as the result of the reporter oligomer used in hybridization, rather than the consensus amplicon pair used. Amplification of a broader range of HPVs is seen on gels or using the restriction digest as confirmation of HPV infection. Both ViraPap and PCR methods of detection gave about a 10% rate of uninterpretable results. PCR methods indicated about 1.7 times as many positives, while showing overall agreement of 77.6% with ViraPap. Agreement on types ranged from 67% to 100%. All methods indicated large fractions of untypable HPVs.

Hartman, L. J., S. R. Coyne, et al. (2005). "Development of a novel internal positive control for Taqman[trademark] based assays." Molecular and Cellular Probes **19**(1): 51.

<http://www.sciencedirect.com/science/article/B6WNC-4F0GR5B-1/2/cdbcfa718a1fdc4b2757ad9df1074bb9>

Development of rapid amplification assays for the detection and identification of biological threat agents has become a focus of diagnostic efforts in recent years. The use of real-time PCR assays as diagnostic tools depends upon two critical processes. First, nucleic acid purification must provide template that is both amplifiable and free of PCR inhibitors. Second, the assays themselves must be sensitive and specific for their nucleic acid targets. A differentiation must be made between results achieved due to the lack of target nucleic acid (true negatives) and those produced due to the inability to amplify target DNA (false negatives) so confidence in negative reactions is possible. False negatives can occur when inhibitors are present in the sample being tested, especially if clinical samples such as blood are analyzed. To address the problem of detecting inhibition in purified nucleic acids, an exogenous internal positive control (IPC) based on Taqman[trademark] chemistry was developed. A previously optimized assay was cloned and the primer and probe sites were mutated to produce novel sequences with no known homology to published sequence data. The IPC was sensitive to a variety of inhibitors, including hemoglobin, heparin, EDTA, humic acids, and fulvic acid. It was also equally sensitive to inhibition when labeled with either 6FAM or ROX dyes. In addition, the IPC was successfully multiplexed with agent specific assays without any loss in their sensitivity. The designed IPC assay has proven to be an effective tool for monitoring inhibitors of PCR and builds confidence in negative results obtained with agent specific assays.

Holmberg, M., J. Wahlberg, et al. (1992). "Colorimetric detection of Plasmodium falciparum and direct sequencing of amplified gene fragments using a solid phase method." Molecular and Cellular Probes **6**(3): 201.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-31/2/cb7625fe7e54ee4c082212a960ac460a>

A rapid colorimetric assay for the detection of DNA from Plasmodium falciparum malaria is described, allowing direct sequencing of amplified fragments in the positive samples. The method is based on amplification by the polymerase chain reaction (PCR), with incorporation of biotin and a lac operator sequence in the amplified target DNA. The PCR product was immobilized on streptavidin-coupled magnetic beads, and detected by the specific binding of an Escherichia coli lac repressor [beta]-galactosidase fusion protein. Positive samples were subsequently treated with alkali to generate single stranded templates, which were used for solid phase genomic sequencing. As targets for amplification and sequencing we selected a region of the gene for the antigen Pf155/RESA and a region of the parasite dihydrofolate reductase gene (PfDHFR/TS). We show here that both of these gene targets can be used for specific detection of P. falciparum in

patient blood samples. Genomic sequencing of five patient isolates revealed no variation in the Pf155/RESA gene fragment. In a comparison of this sequence with conserved protein domains, a marked similarity to the src homology region 3 was detected. A point mutation was found in the PfDHFR/TS gene fragment of one of the clinical samples, replacing Ser108 with Asn. This mutation has earlier been described in pyrimethamine and cycloguanile-resistant strains of *P. falciparum*.

Ibrahim, M. S., J. J. Esposito, et al. (1997). "The potential of 5' nuclease PCR for detecting a single-base polymorphism in Orthopoxvirus." Molecular and Cellular Probes **11**(2): 143.

<http://www.sciencedirect.com/science/article/B6WNC-45M2XMF-N/2/e3c78ce4b57c0c34eb51e77f9fe1f402>

A fluorogenic 5' nuclease PCR assay was evaluated for its ability to specifically detect and differentiate DNA of two Orthopoxvirus species. A pair of consensus primers that target a DNA segment of the Orthopoxvirus haemagglutinin gene, and two oligonucleotide probes, each labelled with a different fluorescent reporter dye and the same quencher dye, were used in a single-tube assay. The assay is based on the 5'→3' nuclease activity of AmpliTaq DNA polymerase that cleaves a fluorescein-labelled hybridized probe. Probe cleavage generates specific fluorescent signals whose intensity can be quantified by fluorometry. After evaluating the effects of various annealing temperatures and probe concentrations and normalizing the emission intensities of the reporter dyes, it was possible to detect and differentiate monkeypox and vaccinia virus DNAs on the basis of a single-base polymorphism. The sensitivity of the 5' nuclease PCR assay is comparable to the sensitivity of ethidium bromide-stained gels, but the assay provides higher specificity and virtually eliminates the need for laborious post-PCR processing.

Isegawa, Y., J. Sheng, et al. (1992). "Selective amplification of cDNA sequence from total RNA by cassette-ligation mediated polymerase chain reaction (PCR): Application to sequencing 6.5 kb genome segment of hantavirus strain B-1." Molecular and Cellular Probes **6**(6): 467.

<http://www.sciencedirect.com/science/article/B6WNC-4DYVPKN-1H/2/5c212d2ea010b38baa61ee9b4580f9e6>

A method, referred to as cassette-ligation mediated polymerase chain reaction (PCR), has been developed to permit selective and specific amplification of cDNA sequence from total cellular RNA. This technique comprises (i) digestion of cDNA with multiple restriction enzymes, (ii) ligation of cleavage products to double-stranded DNA cassettes possessing a corresponding restriction site and (iii) amplification of cassette-ligated restriction fragments containing a short, known sequence (but not all the other ligation products) by PCR using the specific and cassette primers; the specific primer is designed to prime synthesis from the known sequence of the cDNA whereas the cassette primer anneals to one strand of the cassette. Sequencing from the cassette primer provides information to design a new primer for the next walking step. The amplified cDNA fragments are often larger than the maximum DNA fragments (500-600 bp) that can be sequenced without the need of synthesizing internal sequencing primer. Each of such large cDNA fragments is dissected into smaller DNA fragments by repeating cassette-ligation mediated PCR exploiting different restriction sites and different sets of cassette primers. This dissection process reduces the number of specific primers to a minimum, thereby increasing the speed of sequencing and minimizing the overall cost. We have successfully applied this cDNA walking and sequencing by the cassette-ligation mediated PCR to the sequencing of an entire 6.5 kb genome segment of hantavirus strain B-1. The complete sequencing was achieved by four successive walking steps with 13 viral specific and three cassette primers, corresponding to more than 50% reduction in the number of primers necessary to sequence the cognate gene of other strains

belonging to the same virus genus.

Johnson, M., Y. G. Abs El-Osta, et al. (2004). "An electrophoretic tool for the genetic characterisation and delineation of lungworms." Molecular and Cellular Probes **18**(3): 197.

<http://www.sciencedirect.com/science/article/B6WNC-4BYJXJ0-2/2/5a48181bf135895a9186baf26c61c3f>

In the present study, PCR-based single-strand conformation polymorphism (SSCP) analysis of the second internal transcribed spacer (ITS-2) of nuclear ribosomal DNA (rDNA) was applied to the genetic characterisation of *Dictyocaulus* from red deer from New Zealand and to its differentiation from species of lungworm from cattle and other hosts. Based on SSCP profiles, *Dictyocaulus* individuals from red deer from different geographical localities in New Zealand could be readily distinguished from those representing other lungworms examined, irrespective of low-level sequence variability in the ITS-2 (0.4-2.6%) detectable among individuals. The ITS-2 of *Dictyocaulus* from red deer differed in sequence by ~7-35% from congeners from other cervid hosts, demonstrating that this parasite is genetically distinct from other species of *Dictyocaulus* for which ITS-2 sequence data are presently available. The results emphasize the need for a large-scale molecular systematic study of *Dictyocaulus* specimens from various species of cervid and other ruminant hosts and the usefulness of mutation scanning for taxonomic, epidemiological and population genetic investigations.

Latorra, D., K. Arar, et al. (2003). "Design considerations and effects of LNA in PCR primers." Molecular and Cellular Probes **17**(5): 253.

<http://www.sciencedirect.com/science/article/B6WNC-49HMTKW-1/2/d6f7bb5d3260c777aff20f41b8bac8f0>

The effects of comprehensive LNA substitution in PCR primers for amplification of human genomic DNA targets are presented in this report. Previous research with LNA in other applications has shown interesting properties for molecular hybridization including enhanced specificity in allele-specific PCR. Here we systematically modified PCR primers and conditions for the human genomic DNA targets APOB and PAH, along with a [beta]-globin amplification control, to study whether the number and position of LNA residues improves or diminishes amplification sensitivity and specificity. It was observed that the design rules for LNA substitution in PCR primers are complex and depend upon number, position and sequence context. Technical advantages were seen when compared to DNA controls for the best LNA primer designs, which were typically one to a few centrally located LNA residues. LNA advantages include increased maximum annealing temperature (T_{max}) and increased signal with limiting primer or Taq DNA polymerase. Several well-characterized designs exhibited different efficiencies with different brands of hot-start enzymes. Many shorter LNA primers were found to be functional compared to same-length non-functional native DNA controls. These results show that LNA-substituted PCR primers have potential for use in difficult PCR techniques, such as multiplex amplification at higher T_{max}, once firm LNA primer design rules are established.

Letertre, C., S. Perelle, et al. (2003). "Evaluation of the performance of LNA and MGB probes in 5'-nuclease PCR assays." Molecular and Cellular Probes **17**(6): 307.

<http://www.sciencedirect.com/science/article/B6WNC-49V3GFV->

1/2/afd418a82f36e8ac7814c0c9b3a6ca76

The aim of this study was to evaluate the use of Locked Nucleic Acids (LNA) probes in 5'-nuclease PCR, by comparison with Minor Groove Binder (MGB) probes routinely practiced in laboratories on ABI Prism 7700. The comparison was made using a collection of *Staphylococcus aureus* strains that have already been characterized by MGB 5'-nuclease PCR assays in a previous study [Mol Cell Probes, submitted for publication]. The sensitivity and specificity of 5'-nuclease PCR assays targeting the *Staphylococcal* enterotoxin genes sea to see were compared and showed that the LNA and MGB methods were equivalent. In conclusion, the LNA 5'-nuclease PCR assays developed in this work provide a specific and sensitive alternative to the well-established MGB 5'-nuclease PCR assays used for the rapid detection of bacterial pathogens genes on ABI Prism 7700.

Letertre, C., S. Perelle, et al. (2003). "A strategy based on 5' nuclease multiplex PCR to detect enterotoxin genes sea to sej of *Staphylococcus aureus*." Molecular and Cellular Probes **17**(5): 227.

<http://www.sciencedirect.com/science/article/B6WNC-49H0RCT-1/2/479cd70c2a25bd6b2a3dbdd9bb6af9b8>

We describe the development of a strategy based on 5' nuclease multiplex PCR for the rapid detection of nine enterotoxin genes (sea, seb, sec, sed, see, seg, seh, sei, sej) of *Staphylococcus aureus*. The genotyping scheme consists in identifying these nine enterotoxin genes by three 5' nuclease Triplex-PCR assays. The strategy was evaluated using a collection of *S. aureus* reference strains previously examined with conventional PCR assays, and by testing previously characterized food *S. aureus* field strains. The 5' nuclease Triplex-PCR assays correctly detected the se genes in all the reference strains. In tests with field strains there was generally excellent agreement with the results obtained by conventional PCR, except for some strains harbouring variant se genes. The detection limits of the Triplex-PCR assays evaluated using fivefold dilution of recombinant plasmids for each se gene ranged from 16 to 2000 copies of target se genes in the PCR tube. The 5' nuclease Triplex-PCR assays developed are fast and specific, and provide a useful diagnostic tool for the detection and genotyping of se genes. The development of this method is an improvement that should facilitate epidemiological investigations of staphylococcal food poisoning outbreaks.

Liguori, R., A. Argiriou, et al. (2003). "A rapid method for detecting mutations of the human LDL receptor gene by complete cDNA sequencing." Molecular and Cellular Probes **17**(1): 15.

<http://www.sciencedirect.com/science/article/B6WNC-47YY41N-5/2/98c02ea5966e11b99b8eb8ef057985e3>

We have developed and clinically tested a rapid and largely automated procedure to detect mutations in the coding region of a gene of interest. Our method relies on the automated sequencing of the complete cDNA, followed by an advanced mutation search-and-verification routine using an integrated set of computer analysis tools. We have applied our automated procedure to the diagnosis of familial hypercholesterolemia (FH) in 52 unrelated FH families, by sequencing the whole cDNA coding region of the LDLR gene. Here we report the procedures and performance of our method in the identification of the most common types of LDLR mutations: short deletions or insertions and point mutations. Our method can provide a standard procedure for the 'overnight' unequivocal identification of mutations in those genetic diseases where several different mutations, none clearly prominent, may affect a given gene.

Lucotte, G. and T. Champenois (2003). "Duplex PCR-RFLP for simultaneous detection of factor V Leiden and prothrombin G20210A." Molecular and Cellular Probes **17**(5): 267.

<http://www.sciencedirect.com/science/article/B6WNC-49M0NCG-1/2/42146fb5541af3a19ab5c5acde0c0fb3>

The authors have used a primer-engineered duplex polymerase chain reaction (PCR) -restriction fragment length polymorphism (RFLP) for the simultaneous detection of factor V Leiden and prothrombin G20210A mutations. The method involves the generation of HindIII RFLPs, and the restricted amplification products are analyzed by agarose gel electrophoresis in a single gel lane. This method is simple and inexpensive, and readily adaptable to the routine in a clinical molecular diagnostic laboratory other than our own.

Mahbubani, M. H., A. K. Bej, et al. (1990). "Detection of Legionella with polymerase chain reaction and gene probe methods." Molecular and Cellular Probes **4**(3): 175.

<http://www.sciencedirect.com/science/article/B6WNC-4DYVPKN-30/2/d9484e9c36282bf2cab9c01f90e511ac>

Methods were developed for the detection of Legionella in environmental water sources, based upon the polymerase chain reaction (PCR) and gene probes. All species of Legionella, including all 15 serogroups of L. pneumophila tested, were detected by PCR amplification of a 104 bp DNA sequence that codes for a region of 5S rRNA followed by radiolabelled oligoprobe hybridization to an internal region of the amplified DNA. Strains of L. pneumophila (all serogroups) were specifically detected based upon amplification of a portion of the coding region of the macrophage infectivity potentiator (mip) gene. Pseudomonas spp, that exhibit antigenic cross-reactivity in serological detection methods did not produce positive signals in the PCR-gene probe method using Southern blot analyses. Single cell, single gene Legionella detection was achieved with the PCR--gene probe methods.

McIntosh, I., J. R. W. Govan, et al. (1992). "Detection of Pseudomonas aeruginosa in sputum from cystic fibrosis patients by the polymerase chain reaction." Molecular and Cellular Probes **6**(4): 299.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-5/2/cceecc03b890edeaba042e6e9f0a8da65>

A DNA amplification procedure using heat stable Taq polymerase and the polymerase chain reaction is described for the detection of Pseudomonas aeruginosa in specimens from cystic fibrosis patients. A set of primers was selected on the basis of the nucleotide sequence of the algD gene encoding GDP mannose dehydrogenase, a major enzyme in the biosynthesis of alginate by P. aeruginosa. Using this set of primers in conjunction with the polymerase chain reaction, P. aeruginosa could be specifically detected, with a sensitivity approximating 10 bacteria, in sputum harbouring large numbers of other respiratory pathogens, including Staphylococcus aureus and Haemophilus influenzae. These results suggest that amplification of specific sequences within the algD gene by the polymerase chain reaction may provide a highly sensitive and specific tool for the detection of P. aeruginosa in the early stages of pulmonary colonization.

Rahn, K., S. A. De Grandis, et al. (1992). "Amplification of an *invA* gene sequence of *Salmonella typhimurium* by polymerase chain reaction as a specific method of detection of *Salmonella*." Molecular and Cellular Probes 6(4): 271.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-2/2/97da22fe5149c7283a408d9e24000e0c>

Amplification of nucleotide sequences within the *invA* gene of *Salmonella typhimurium* was evaluated as a means of detecting *Salmonella*. A collection of 630 strains of *Salmonella* comprising over 100 serovars, including the 20 most prevalent serovars isolated from animals and humans in Canada, was examined. Controls consisted of 142 non-*Salmonella* strains comprising 21 genera of bacteria. Cultures were screened by inoculating a single colony of bacteria directly into a polymerase chain reaction (PCR) mixture which contained a pair of primers specific for the *invA* gene. The specific PCR product was a 284 bp DNA fragment which was visualized in 2% agarose gels. With the exception of two *S. litchfield* and two *S. senftenberg* strains, all *Salmonella* strains were detected. In contrast, none of the non-*Salmonella* strains yielded the specific amplification product. Non-specific amplification of a few non-*Salmonella* strains resulted in a product that was distinctly different in size from the specific 284 bp product. Specificity of amplification was further confirmed by demonstration of hybridization of a ³²P-labelled *invA* gene fragment only to the specific 284 bp product. The detection of 99.4% of *Salmonella* strains tested and the failure to specifically amplify DNA from non-*Salmonella* strains confirm that the *invA* gene contains sequences unique to *Salmonella* and demonstrate that this gene is a suitable PCR target, with potential diagnostic applications.

Rand, K. H. and H. Houck (1990). "Taq polymerase contains bacterial DNA of unknown origin." Molecular and Cellular Probes 4(6): 445.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-4Y/2/93b2d51a768c56b297236c561b8c74b9>

The polymerase chain reaction (PCR) was carried out with the highly conserved *E. coli* ribosomal RNA gene sequences 1376-1395 and 1521-1540. Using these primers and reaction conditions specified by the manufacturer(s), a 165 bp fragment was synthesized using Taq polymerase from three different sources in the absence of any added template. Restriction enzyme analysis suggests the source of this bacterial DNA is neither *E. coli* nor *Thermus aquaticus*. A variety of different methods to eliminate it such as treatment with DNase, restriction enzyme digestion, and CsCl₂ density gradient centrifugation were unsuccessful. Since the bacteria in which the Taq polymerase is produced are not the source of the DNA, some step(s) in the purification or reagents added to the enzyme must be involved. Thus it is likely other biological products are similarly contaminated. Although the problem is easily dealt with by running a no-template control and choosing other primers if a problem exists, it is important to recognize the potential for a false-positive result.

Read, S. C., R. C. Clarke, et al. (1992). "Polymerase chain reaction for detection of verocytotoxigenic *Escherichia coli* isolated from animal and food sources." Molecular and Cellular Probes 6(2): 153.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471-5H/2/9d8f427eb96295c62e6c55d37dbf5017>

Animals and their by-products have been implicated as important sources of verocytotoxigenic *Escherichia coli* (VTEC) associated with disease in humans. VTEC comprise a wide range of

serotypes and produce a variety of closely related verocytotoxins (VT). A pair of oligonucleotide primers, targeting conserved sequences found in VT1, VT2 and VTE genes, was used to develop a polymerase chain reaction (PCR) procedure to detect all types of VTEC. Supernatants of boiled broth cultures of VTEC (223 strains) isolated from ground beef, ground pork, raw milk, bovine faeces and porcine faeces; non-VTEC *E. coli* (72 strains); and other enteric and food bacteria (76 strains) were tested by PCR. The verocytotoxigenicity of these strains was verified by the Vero cell assay. All 223 VTEC isolates, comprising over 50 different serotypes, were detected by the PCR procedure. *Shigella dysenteriae* type 1 was the only other bacterium that was positive in this assay. As little as 1 pg of VTEC DNA and as few as 17 cfu of VTEC could be detected with this method. The results indicate that these primers detect VTEC over a wide range of serotypes. This method may be applicable as a screening procedure for the detection of VTEC in samples of foods and faeces.

Rodriguez-Lazaro, D., J. Lloyd, et al. (2004). "Unexpected detection of DNA by nucleic acid sequence-based amplification technique." Molecular and Cellular Probes **18**(4): 251.

<http://www.sciencedirect.com/science/article/B6WNC-4BV4VGG-1/2/7ce3341590f1c11cfea8a6834b707551>

Nucleic acid sequence-based amplification (NASBA) is a technique that has been previously shown to selectively mediate the detection of RNA in microbial cells. In a series of tests, nucleic acids were extracted from *Salmonella enterica* serotype Typhimurium and *Mycobacterium avium* subsp. paratuberculosis, and subjected to four enzymatic treatments prior to NASBA. These enzymatic treatments were DNase, RNase, S1 nuclease, and RNase/S1 nuclease. The results obtained were different for the two bacteria. With *S. enterica* serotype Typhimurium, RNase and RNase/S1 nuclease abolished the NASBA signal, as expected. But with *M. avium* subsp. paratuberculosis RNase, S1 nuclease, and RNase/S1 nuclease had no effect on the NASBA signal, whereas DNase treatment abolished it. This indicates that in the latter bacterium, NASBA can detect DNA, and demonstrates the necessity of verifying the nucleic acid origin of a NASBA signal if detection of RNA is objective.

Sacramento, D., H. Bourhy, et al. (1991). "PCR technique as an alternative method for diagnosis and molecular epidemiology of rabies virus." Molecular and Cellular Probes **5**(3): 229.

<http://www.sciencedirect.com/science/article/B6WNC-4DYVPKN-1Y/2/5f259cecdfb8fb9375f9f963fdf08609>

We have investigated the PCR amplification technique of viral nucleic acids as an alternative protocol for diagnosis and epidemiological studies of rabies virus. A primer set mapping in the nucleoprotein cistron allowed a specific and sensitive amplification of infected brain material, fulfilling the diagnosis requirements. One hundred samples checked by Southern or dot-blot analysis using both radioactive and non-radioactive probes showed identical results in parallel with routine techniques. For molecular epidemiological studies we selected another set of conserved primers flanking the highly evolutive pseudogene ([Psi] gene) region. This set was found to be efficient for all tested fixed rabies virus strains or wild rabies virus isolates as well as the rabies-related Mokola virus. We describe a progressive characterization of the strain that could be extended from rapid typing by a limited panel of restriction enzymes, to the ultimate identification of the nucleotide sequence by an original direct sequencing technique of amplified segments.

Stanier, P., A. D. Kitchen, et al. (1992). "Detection of human cytomegalovirus in peripheral mononuclear cells and urine samples using PCR." Molecular and Cellular Probes **6**(1): 51.

<http://www.sciencedirect.com/science/article/B6WNC-4DYVPKN-2S/2/f33be0efa66bb597043a165b0d7b6480>

Samples of peripheral blood lymphocytes from 105 different blood donors were investigated for the presence of human cytomegalovirus (HCMV) DNA using the polymerase chain reaction (PCR) with primers specific for the Pst / w fragment (IE region). Viral DNA sequences were detected in 53 samples, a fifth of which had been previously serotyped as HCMV negative. In the latter cases, Western blot analysis re-determined two out of three individuals that were resampled as seropositive. PCR could therefore be used to extend existing methods employed for the identification of HCMV infected blood samples prior to transfusion to individuals in high risk groups. In addition, the value of PCR as a diagnostic test was evaluated in a small pilot study by comparing the results obtained with urine samples from babies suffering congenital infection and from other high risk patients, with data obtained by isolation of infectious virus or through the detection of immediate early antigens in infected cultures. Data from this study indicated that PCR is at least as sensitive as the other methods used in HCMV diagnosis.

Tondeur, S., O. Agbulut, et al. (2004). "Overcoming bacterial DNA contamination in real-time PCR and RT-PCR reactions for LacZ detection in cell therapy monitoring." Molecular and Cellular Probes **18**(6): 437.

<http://www.sciencedirect.com/science/article/B6WNC-4DBSV8W-1/2/9c12b833a03a8e8eb03c6843315499f7>

Since the introduction of the polymerase chain reaction the presence of contaminating bacterial DNA in the Taq polymerase preparations has hampered the use of this technique in microbiology. Lately, this inconvenience has equally impeded gene quantification in the field of cell or gene therapy, where bacterial genes such as LacZ are often used as tags to detect vectors or cells after their injection in the recipient organism. Several means to overcome the DNA contamination of Taq Polymerase have been reported with variable degrees of decontamination efficiency and alteration of the PCR reaction. Here we propose two protocols to efficiently quantify DNA or RNA from the LacZ gene by real-time PCR using either decontamination by low concentrations of DNase I prior to PCR amplification or a highly purified Taq Polymerase which is devoid of detectable contamination.

Vaccari, G., M. Conte, et al. (2004). "Primer extension assay for prion protein genotype determination in sheep." Molecular and Cellular Probes **18**(1): 33.

<http://www.sciencedirect.com/science/article/B6WNC-49RCFKJ-1/2/7adcbb930543adceeb15906ec4f589f5>

Scrapie is a transmissible spongiform encephalopathy (TSE) which affects sheep and goats. TSEs are characterised by the conversion of the cellular prion protein (PrP^C) into the pathological form PrP^{Sc}. The occurrence of scrapie in sheep is influenced by polymorphisms in the PrP gene; in particular, three codons (136, 154 and 171) are important in conditioning the susceptibility/resistance of sheep to the disease, with the Val/Val136 Arg/Arg154 Gln/Gln171 genotype being the most susceptible and the Ala/Ala136 Arg/Arg154 Arg/Arg171, the most resistant one. The latter genotype seems to confer, in sheep, resistance to the oral infection with bovine spongiform encephalopathy, as well. The selection of genetically resistant sheep

populations represents the basis of the recent strategies against ovine TSE in the European Union (EU). Herein, we describe a rapid and simple method, based on the primer extension technique, for PrP genotype determination at codons 136, 154 and 171. Intra-laboratory validation of the method showed accuracy levels comparable to those of sequencing analysis. Such method could be used for both the application of the EU policies requiring PrP genotype analysis in all ovine TSE cases, and the large-scale genotyping claimed by the implementation of breeding programmes for genetic resistance to TSE in sheep.

Vallo, L., E. Bonifazi, et al. (2005). "Characterization of a single nucleotide polymorphism in the ZNF9 gene and analysis of association with myotonic dystrophy type II (DM2) in the Italian population." Molecular and Cellular Probes **19**(1): 71.

<http://www.sciencedirect.com/science/article/B6WNC-4DSM9Y0-5/2/90b941f20455150b556f1fd3ace8c091>

Myotonic dystrophy type 2 (DM2) is a dominant inherited disorder clinically similar to myotonic dystrophy type 1 (DM1) with a peculiar pattern of multisystemic phenotypic features. The mutation responsible for DM1 is a CTG repeat in the 3' UTR of the dystrophin protein kinase gene (DMPK) on chromosome 19q13.3, while DM2 is caused by an unstable CCTG expansion in intron 1 of the zinc finger protein 9 gene (ZNF9) on chromosome 3q21.3. Southern blotting analysis is the conventional test used to determine the size of the repeats in the molecular diagnosis of DM2. However, the large number of CCTG repeats and their somatic instability complicates this diagnostic protocol. In order to improve the DM2 test, we have recently characterised a single nucleotide polymorphism located in the first intron of the ZNF9 gene. This SNP consists in a C to A nucleotide change, which creates or disrupts an Apal enzyme restriction site, easily detectable by PCR amplification followed by restriction analysis. We genotyped this SNP in 30 unrelated DM2 patients and 70 unrelated Italian healthy individuals. Our results show that this polymorphism is in linkage disequilibrium with the DM2 mutation.

Vandenbergh, D. J., M. D. Grant, et al. (2003). "A simple tandem repeat polymorphism is present in the eighth intron of FLJ12960, a possible queuine salvage enzyme gene." Molecular and Cellular Probes **17**(6): 319.

<http://www.sciencedirect.com/science/article/B6WNC-49HMTKW-2/2/4d1d7a37d132540e2dc4690425669469>

The putative gene FLJ12960 was identified from sequence analysis of the human genome and predicted to be a member of the family of tRNA-guanine-transglycosylases for queuine biosynthesis by protein sequence similarity at the Zn-binding site (Locus Link #79691 at <http://www.ncbi.nlm.gov/LocusLink/>). FLJ12960 is immediately downstream of the Dopamine Receptor D3 (DRD3) gene. A Simple Tandem Repeat (STR) polymorphism was identified in intron 8 of the FLJ12960 gene. Primers designed to amplify the CA repeat detect 16 alleles from 121 to 151 base pairs, with a heterozygosity of 0.74.

Yolken, R. H., A. M. Sierra-Honigmann, et al. (1991). "Solid phase capture method for the specific amplification of microbial nucleic acids--avoidance of false-positive and false-negative reactions." Molecular and Cellular Probes **5**(2): 151.

<http://www.sciencedirect.com/science/article/B6WNC-4DYN471->

23/2/da37722fa139a8452c19708354977b63

DNA amplification assays such as the polymerase chain reaction are being developed for the amplification of small quantities of microbial nucleic acids. These assays offer the potential for a great deal of sensitivity. However, the high level of sensitivity increases the likelihood of cross-contamination of amplified products and the generation of false-positive reactions. In addition, substances in body fluids can inhibit the efficient performance of the amplification reactions. We have developed an assay format in which microbial nucleic acids are specifically bound to a solid phase surface. Contaminating DNA and enzyme inhibitors present in the sample are removed by washing prior to the performance of the amplification reaction. We could use this system to amplify and detect small amounts of HIV DNA diluted in whole blood. The assay system could distinguish target DNA from contaminating DNA fragments generated by prior amplification reactions.

Yoshitomi, K. J., K. C. Jinneman, et al. (2003). "Optimization of a 3'-minor groove binder-DNA probe targeting the uidA gene for rapid identification of Escherichia coli O157:H7 using real-time PCR." Molecular and Cellular Probes **17**(6): 275.

<http://www.sciencedirect.com/science/article/B6WNC-49HMTKW-3/2/b8acd04ed072ee4b691f52a73d753c57>

Enterohemorrhagic Escherichia coli are harmful human pathogens capable of causing bloody diarrhea and vomiting. An important serotype commonly associated with human illness is the E. coli O157:H7 serotype. Unlike other real-time polymerase chain reaction (PCR) methods for identifying E. coli O157:H7, this study describes the development and optimization of a real-time PCR method targeting a conserved point mutation at +93 in the uidA (gusA) gene that is unique to O157:H7, distinguishing it from non-O157:H7 serotypes. A TET-labeled Minor Groove Binder (MGB) DNA probe was designed for use in a 5' nuclease PCR assay. Using a panel of two E. coli O157:H7 strains, three E. coli non-O157:H7 strains, and one non-E. coli species, the assay was optimized for the specific detection of the E. coli O157:H7 strains. Optimal conditions were identified at high anneal/extend temperatures, low magnesium concentrations, and low probe concentrations, resulting in correct identification of E. coli O157:H7 and non-O157:H7 strains. The improved specificity of MGB probes for single base pair mismatches such as the +93 uidA mutation provides a novel approach towards rapid identification of E. coli O157:H7.

<http://www.sciencedirect.com/science/article/B6T9P-3Y5FP3Y-2/2/3311dceaa2bbf5de1f5de54ef766e8c6>

Allan, S. M., D. C. Harrison, et al. (2001). "Selective increases in cytokine expression in the rat brain in response to striatal injection of [alpha]-amino-3-hydroxy-5-methyl-4-isoxazolepropionate and interleukin-1." Molecular Brain Research **93**(2): 180.

<http://www.sciencedirect.com/science/article/B6T07-443K68G-D/2/88eaf548edc608aad9b83955b407fa6>

A number of cytokines contribute to acute experimental neurodegeneration. The cytokine response can have detrimental or beneficial effects depending on the temporal profile and balance between pro- and anti-inflammatory molecules. Our recent data suggest that the pro-inflammatory cytokine interleukin-1[beta] (IL-1[beta]) acts at specific sites (e.g., the striatum) in the rat brain to cause distant cortical injury, when co-administered with the potent excitotoxin [alpha]-amino-3-hydroxy-5-methyl-4-isoxazolepropionate (S-AMPA). The objective of the present study was to investigate changes in the expression of several cytokines simultaneously in the rat striatum and cortex after intrastriatal administration of vehicle, S-AMPA or human recombinant (hr) IL-1[beta] alone or S-AMPA co-injected with hrIL-1[beta] using reverse transcription-polymerase chain reaction (RT-PCR; Taqman(TM) fluorogenic probes) and enzyme-linked immunosorbent assay (ELISA). Injection of S-AMPA alone increased IL-6 mRNA expression in the ipsilateral striatum after 8 h, whilst striatal injection of IL-1[beta] alone increased local IL-1[beta] and IL-1ra mRNAs. The levels of mRNA encoding IL-1[alpha], IL-1[beta], IL-1ra, IL-6, IL-10 and TNF[alpha] were markedly elevated in the ipsilateral cortex 8 h after co-injection of S-AMPA and hrIL-1[beta]. Cortical mRNA levels for IL-4, IL-18, TGF[beta] and IFN[gamma] were not significantly different between treatment groups after 2 h or 8 h. A similar pattern of change in the levels of IL-1[alpha] and IL-6 protein was observed 8 h after treatment. These data demonstrate selective increases in the expression of cytokines in areas of remote cell death in response to administration of hrIL-1[beta] and S-AMPA. Such cytokines may be involved in the ensuing damage, and further clarification of their actions could aid future therapeutic strategies for several acute neurodegenerative disorders.

Barritt, L. C., B. Fritsch, et al. (1999). "Characterization of G-protein [beta][gamma] expression in the inner ear." Molecular Brain Research **68**(1-2): 42.

<http://www.sciencedirect.com/science/article/B6T07-3WF80M0-5/2/6eb6e5a0f62e14c89d80ea86a77262b6>

Heterotrimeric guanine nucleotide binding proteins (G-proteins) are composed of a diverse set of [alpha], [beta], and [gamma] subunits, which couple cell surface receptors to intracellular effectors, such as adenylyl cyclase, phospholipase C[beta], and ion channels. Both the G[alpha] and the G[beta][gamma] dimers mediate effector activity and are believed to contribute to the complexity of the signaling pathway. Molecular and immunocytochemical techniques were employed to determine diversity of G[beta] and G[gamma] subunit expression in the murine inner ear. PCR-based assessment of [lambda]ZAP unidirectional cDNA libraries, representing the cochlea and inner ear hair cells, indicated all five known G[beta] subunits were present in the cochlea, while only a subset of G[gamma] isoforms were found. New or novel G-protein [beta] and [gamma] subunits were not detected. cDNAs representing G[beta]1-4 and G[gamma]2, G[gamma]3, G[gamma]5, G[gamma]8olf subunit transcripts were isolated. In addition, cDNAs corresponding to the G[beta]5 and G[gamma]11 isoforms exhibited restricted expression to inner and outer hair cells, respectively. Antisera specific for G[beta]3, G[beta]4, G[gamma]3, G[gamma]5 and G[gamma]11 stained spiral ganglion and neurosensory hair cells. A unique finding was the variable topological distribution of G[gamma]3 in the spiral ganglion cells along

the cochlear axis. Collectively, our results demonstrate a complementary as well as differential distribution pattern for G[beta] and G[gamma] isoforms exists in the inner ear. The co-localization of various G-protein isoforms within the same cell type suggests specific combinatorial G[beta] and G[gamma] subunit associations may preferentially be formed. Thus, the detection of multiple subunits presumably reflects the extent of the functional diversity of inner ear signaling pathways and should provide specificity of G-protein mediated pathways.

Bates, S., S. J. Read, et al. (2001). "Characterisation of gene expression changes following permanent MCAO in the rat using subtractive hybridisation." Molecular Brain Research **93**(1): 70.

<http://www.sciencedirect.com/science/article/B6T07-43V9YTJ-F/2/0e685cf73e3b9f3ce2b370d652df66b5>

Failure of several putative neuroprotectants in large multicentred clinical trials has re-focussed attention on the predictability of pre-clinical animal models of stroke. Model characterisation and relationship to heterogeneous patient sub-groups remains of paramount importance. Information gained from magnetic resonance imaging (MRI) signatures indicates that the Zea Longa model of rat middle cerebral artery occlusion may be more representative of slowly evolving infarcts. Understanding the molecular changes over several hours following cerebral ischaemia will allow detailed characterisation of the adaptive response to brain injury. Using a fully characterised model of Zea Longa middle cerebral artery occlusion we have used the representational difference analysis (RDA) subtractive hybridisation method to identify transcripts that accumulate in the ischaemic cortex. Along with a number of established ischaemia-induced gene products (including MCP-1, TIMP-1, hsp 70) we were also able to identify nine genes which have not previously been shown to accumulate following focal ischaemia (including SOCS-3, GADD45[gamma], Xin).

Bellingham, J., D. Whitmore, et al. (2002). "Zebrafish melanopsin: isolation, tissue localisation and phylogenetic position." Molecular Brain Research **107**(2): 128.

<http://www.sciencedirect.com/science/article/B6T07-474FXT3-4/2/8e05d23db514d58b6a63a2c647a3d309>

Photoreception is best understood in retinal rods and cones, but it is not confined to these cells. In non-mammals, intrinsically photosensitive cells have been identified within several structures including the pineal, hypothalamus and skin. More recently novel light sensitive cells have been identified in the inner/basal retina of both teleosts and rodents. Melanopsin has been proposed as the photopigment mediating many of these non-rod, non-cone responses to light. However, much about the melanopsin gene family remains to be clarified including their potential role as photopigments, and taxonomic distribution. We have isolated the first orthologue of melanopsin from a teleost fish and show expression of this gene in a sub-set of retinal horizontal cells (type B). Zebrafish melanopsin, and orthologues of this gene, differ markedly from the vertebrate photopigment opsins. The putative counterion is not a glutamate but a tyrosine, the putative G-protein binding domain in the third cytoplasmic loop is not conserved, and they show low levels of amino acid identity (~27%) to both the known photopigment opsins and to other members of the melanopsin family. Mouse melanopsin is only 58% identical to *Xenopus*, and 68% identical to zebrafish. By contrast, the photosensory opsin families show ~75% conservation. On the basis of their structure, genomic organisation, discrete evolutionary lineage, and their co-expression with other opsins, the melanopsins are not obvious photosensory opsins. They might represent a separate branch of photopigment evolution in the vertebrates or they may have a non-direct photosensory function, perhaps as a photoisomerase, in non-rod, non-cone light detection.

Beltramo, M., M. Campanella, et al. (2003). "Gene expression profiling of melanocortin system in neuropathic rats supports a role in nociception." Molecular Brain Research **118**(1-2): 111.

<http://www.sciencedirect.com/science/article/B6T07-49FRBP6-2/2/418586ccfd813f10342be96f072ac1bf>

The melanocortin (MC) system is involved in several biological functions. Its possible role in nociception has recently attracted attention in the field. Published data suggest that melanocortin antagonists are analgesic and agonists are hyperalgesic. Gene expression information about the MC system components (receptor, agonist and antagonist) in pain relevant areas is at present limited. To deepen our knowledge, we studied the expression of MC system components in naive, sham and neuropathic rat spinal cord and dorsal root ganglia (DRG) by PCR and quantitative real-time PCR. MC4 receptor, proopiomelanocortin (POMC) and agouti-related protein (AgRP) transcripts were detected in both spinal cord and DRG, whereas MC3 receptor was detected only in the spinal cord. To study the relationship between the MC system and chronic pain, we used the chronic constriction injury model and gene expression analysis was performed in rats showing both tactile allodynia and thermal hyperalgesia. MC4 and POMC transcript were upregulated in the spinal cord of neuropathic rats, whereas MC3 and AgRP expression were unaffected. Thus, this study demonstrates for the first time the presence of AgRP in the spinal cord and DRG, suggesting that it could play a role in the regulation of MC system activity. In addition, the upregulation of POMC and MC4, in parallel with the presence of tactile allodynia and thermal hyperalgesia, further supports the idea of MC system involvement in nociception.

Bhogal, R. K., A. L. Mitchell, et al. (2004). "Identification of putative rat ribonuclease III by differential display: a novel rat mRNA expressed in a circadian manner in the rat suprachiasmatic nucleus." Molecular Brain Research **131**(1-2): 51.

<http://www.sciencedirect.com/science/article/B6T07-4DR13JP-B/2/f90d9062b19e5ef202731f2461fac106>

The suprachiasmatic nucleus (SCN) of the hypothalamus constitutes the principal site responsible for the generation and entrainment of circadian rhythms in mammals. The mechanisms of the circadian clock involve periodic gene expression. Here we report the use of differential display reverse transcriptase polymerase chain reaction to identify a novel rat mRNA sequence which is highly homologous to human ribonuclease III. Analysis of its expression in the rat brain by in situ hybridization histochemistry showed this transcript to be expressed at differing intensities at various sites. Temporal variation in expression was observed in the SCN, with a peak at circadian time (CT) 2 and a nadir at CT14. No significant changes in its expression were detected across the cycle within the supraoptic nucleus, cingulate cortex or caudate putamen.

Bigl, M., M. Beck, et al. (2000). "Altered phosphofructokinase mRNA levels but unchanged isoenzyme pattern in brains from patients with Alzheimer's disease." Molecular Brain Research **76**(2): 411.

<http://www.sciencedirect.com/science/article/B6T07-400WXRS-X/2/1ae384a937ca3b65746974b08f169e36>

In order to find out whether the increased phosphofructokinase (PFK) activities observed in brains from Alzheimer's disease (AD) patients are associated with alterations in PFK mRNA levels, we

determined total PFK mRNA and the three different PFK isoenzyme mRNAs in AD and control patients by ribonuclease protection assay (RPA) and quantitative RT-PCR. PFK mRNA levels were found increased in some brain areas in AD patients. While all three PFK isoenzyme mRNAs were detectable in every studied brain sample, no changes of the PFK isoenzyme pattern were observed in patients with AD.

Bloom, D. C., N. T. Maidment, et al. (1995). "Long-term expression of a reporter gene from latent herpes simplex virus in the rat hippocampus." Molecular Brain Research **31**(1-2): 48.

<http://www.sciencedirect.com/science/article/B6T07-3YKMC2T-5/2/3cb2472e83b91909303540dc73f6c6f4>

A problem in utilizing herpes simplex virus (HSV) as a vector for expression of foreign genes in CNS neurons has been the inability to facilitate long-term expression of the engineered genes. Previously, we showed that the murine moloney leukemia virus LTR would drive [beta]-galactosidase ([beta]-gal) transcription for extended periods from the latent viral genome in sensory, but not motor neurons. In this communication we further evaluate the utility of the LTR promoter for use in long-term expression vectors. Following stereotactic injection of 8117/43 (an ICP4 minus, non-replicating virus with the LTR driving the [beta]-gal gene, or KD6 (an ICP4 minus non-replicating virus not expressing [beta]-gal) into the hippocampus of rats, polymerase chain reaction (PCR) analysis of viral DNA after 2 months indicated that latent infections were established. Assaying by both -gal staining and reverse transcriptase PCR we demonstrate that (1) [beta]-gal can be detected for at least 6 months in hippocampal neurons, and (2) although the number of [beta]-gal transcripts in these cells drops considerably by 2 weeks, they can be detected during the period studied. These studies indicate that the LTR promoter is active and affords long-term expression in the CNS, albeit at comparatively low levels compared to those observed at acute times.

Brandle, U., E. Guenther, et al. (1998). "Gene expression of the P2X receptors in the rat retina." Molecular Brain Research **59**(2): 269.

<http://www.sciencedirect.com/science/article/B6T07-3TMX1Y9-H/2/c6b79f7b017bb9a18669974221d4c62d>

Molecular-biological methods were used to demonstrate the expression of six P2X receptor subunits (P2X1-P2X6) in retina and choroid. Despite the considerable evidence for signalling by extracellular nucleotides in other sensory systems, few studies have been undertaken in the eye. RT-PCR for the detection of P2X subunit mRNA in the rat of different postnatal developmental stages (P23-P210) revealed the presence of P2X2 and P2X4 mRNA in the retina and choroid; P2X3, and P2X5 were detected only in the retina. There was no evidence for P2X1 and P2X6 mRNA in the ocular tissue under investigation. Our data suggest that extracellular ATP may have influences on visual processing.

Brandle, U., K. Kohler, et al. (1998). "Expression of the P2X7-receptor subunit in neurons of the rat retina." Molecular Brain Research **62**(1): 106.

<http://www.sciencedirect.com/science/article/B6T07-3V3X5DR-G/2/8d54e456793a80af454b980a54f53be7>

Despite the considerable evidence of signaling by extracellular nucleotides in other sensory systems, few studies have been undertaken in the eye. Molecular and immunohistochemical methods were used to demonstrate the expression and cellular localization of the P2X7 receptor subunit in the retina and choroid. RT-PCR was used for the detection of P2X7 subunit mRNA in the rat of different postnatal developmental stages (P23-P210) and revealed the presence of P2X7-mRNA in the retina, but not in the choroid. In the adult rat retina, immunolabelling for P2X7 was detected in a number of cells in the inner nuclear layer (INL) and ganglion cell layer (GCL), suggesting different types of amacrine cells and ganglion cells. These results demonstrate for the first time the expression of the P2X7 receptor in the mammalian retina and furthermore in distinct neuronal cell populations. Our data suggest that extracellular ATP may provide both neuromodulatory and trophic influences on visual processing.

Burcelin, R., A. G. Rodriguez-Gabin, et al. (1997). "Molecular analysis of the monomeric GTP-binding proteins of oligodendrocytes." Molecular Brain Research **50**(1-2): 9.

<http://www.sciencedirect.com/science/article/B6T07-3S13DNH-2/2/24ab43a84952fe6d7557cf04449caa86>

Vesicle transport plays an important role in the formation of myelin. Transport of proteins, including proteolipid protein and myelin associated glycoprotein, from their site of synthesis in the endoplasmic reticulum in the perikaryon of the oligodendrocytes, to myelin, takes place via carrier vesicles. The mechanisms that regulate vesicle transport in oligodendrocytes are largely unknown. The presence of monomeric GTP-binding proteins in myelin and oligodendrocytes suggested the hypothesis that these proteins participate in the regulation of vesicle transport. In an attempt to identify the Rab and Rho GTP-binding proteins present in oligodendrocytes, a cDNA library specific for these proteins was generated using a reverse transcriptase-polymerase chain reaction (RT-PCR) approach. Twelve different clones containing sequences that coded for members of the Rab and Rho families of GTP-binding proteins were isolated. This group includes Rab1, -1b, -2, -5b, -5c, -7, -8, -12, -14, -23 and Rho A. One additional clone revealed a novel cDNA sequence. Analysis of the effector loop motif indicated that this sequence encodes for a member of the Rab family. We refer to this new sequence as Rab0. Comparison of Rab0 with the most similar rat Rab sequences, Rab 14 and Rab 22, and with a recently cloned human Rab22b, showed a 71%, 72% and 94% identity, respectively. By RT-PCR analysis the Rab0 mRNA was found to be mainly expressed in oligodendrocytes and to a lesser extent in oligodendrocyte precursors, astrocytes and microglia. Moreover, the highest levels of Rab0 mRNA were observed in areas of the brain that are heavily myelinated. Rab0 mRNA was also detected in other tissues such as kidney, liver, skeletal muscle. These data provide initial evidence regarding signal transduction pathways that regulate intracellular transport in oligodendrocytes.

Cadet, P., W. Zhu, et al. (2002). "Cold stress alters *Mytilus edulis* pedal ganglia expression of [mu] opiate receptor transcripts determined by real-time RT-PCR and morphine levels." Molecular Brain Research **99**(1): 26.

<http://www.sciencedirect.com/science/article/B6T07-44VX5V7-4/2/ce24b8ec47ac8231f1defa1f6b2fe96f>

Previous pharmacological, biochemical and molecular evidence prove that [mu]-subtype opiate receptors and opiate alkaloids, i.e. morphine, are present in the ganglionic nervous system of the mollusk *Mytilus edulis* (bivalve). We now present molecular evidence on the effect of rapid temperature changes on [mu] opiate receptor expression and morphine levels. Using primers, a labeled Taq-Man probe derived from the human neuronal [mu]1 opiate receptor, and real-time RT-PCR to measure the expression of [mu] transcripts from *Mytilus* pedal ganglia, we observe, in

animals placed in cold water from room temperature, an enhanced morphine and morphine 6 glucuronide level in addition to a decrease in $[\mu]$ opiate receptor gene expression. This study provides further evidence that $[\mu]$ -type opiate receptors and morphine are expressed in mollusk ganglia and appear to be involved in physiological processes responding to thermal stress.

Cai, F., W. M. Campana, et al. (1999). "Transforming growth factor- $[\beta]$ 1 and glial growth factor 2 reduce neurotrophin-3 mRNA expression in cultured Schwann cells via a cAMP-dependent pathway." Molecular Brain Research **71**(2): 256.

<http://www.sciencedirect.com/science/article/B6T07-3XNK0RN-F/2/81fa1fbda4a1afb3bb1327e90361648a7>

The aim of the study was to determine which factors regulated the expression of neurotrophin-3 (NT-3) mRNA in cultured primary Schwann cells derived from sciatic nerve of neonatal rats. Treatment of primary Schwann cells with the adenylate cyclase activator, forskolin, or the cAMP agonist, 8-Br-cAMP, induced a significant reduction in NT-3 transcript levels. Transforming growth factor- $[\beta]$ 1 (TGF- $[\beta]$ 1) and glial growth factor 2 (GGF2) also reduced the levels of NT-3 mRNA in a dose and time-dependent manner. Treatment with nerve growth factor, brain-derived neurotrophic factor, NT-3, ciliary neurotrophic factor or interleukin-1 $[\beta]$ was without effect. The TGF- $[\beta]$ 1, GGF2 and forskolin dependent reduction in NT-3 mRNA levels involved a destabilization of transcripts which was antagonised by co-treatment with cycloheximide. The cAMP-dependent protein kinase A (PKA) inhibitor, H-89, blocked the reduction in levels of NT-3 mRNA induced by TGF- $[\beta]$ 1, GGF2 and forskolin. The data show that the effects of TGF- $[\beta]$ 1, GGF2 and forskolin on the downregulation of NT-3 mRNA, at least in part, were due to a post-transcriptional event involving a labile protein intermediate under the control of PKA. The results suggest that the down-regulation of NT-3 mRNA in Schwann cells at a site of peripheral nerve damage may be mediated via a cAMP-dependent pathway and possibly involve neuroma-related elevations in TGF- $[\beta]$ 1 and GGF2.

Calver, A. R., D. Michalovich, et al. (2003). "Molecular cloning and characterisation of a novel GABAB-related G-protein coupled receptor." Molecular Brain Research **110**(2): 305.

<http://www.sciencedirect.com/science/article/B6T07-47X149W-B/2/834598b7e23d23e019ae9211c295936f>

Using a homology-based bioinformatics approach we have analysed human genomic sequence and identified the human and rodent orthologues of a novel putative seven transmembrane G protein coupled receptor, termed GABABL. The amino acid sequence homology of these cDNAs compared to GABAB1 and GABAB2 led us to postulate that GABABL was a putative novel GABAB receptor subunit. The C-terminal sequence of GABABL contained a putative coiled-coil domain, di-leucine and several RXR(R) ER retention motifs, all of which have been shown to be critical in GABAB receptor subunit function. In addition, the distribution of GABABL in the central nervous system was reminiscent of that of the other known GABAB subunits. However, we were unable to detect receptor function in response to any GABAB ligands when GABABL was expressed in isolation or in the presence of either GABAB1 or GABAB2. Therefore, if GABABL is indeed a GABAB receptor subunit, its partner is a potentially novel receptor subunit or chaperone protein which has yet to be identified.

Cappellini, C., P. Malatesta, et al. (1999). "Characterization of a cloned *Xenopus laevis* Serotonin 5-HT_{1A}

receptor expressed in the NIH-3T3 cell line." Molecular Brain Research **63**(2): 380.

<http://www.sciencedirect.com/science/article/B6T07-3VH80K8-R/2/f7bd4d16589cef9231e68ab7cef0d3f4>

In a previous work we isolated a *Xenopus* 5-HT_{1A} receptor gene and now report the characterization of this receptor. The HindIII-XbaI fragment of this gene was cloned into the pcDNA I NEO vector and stably transfected into eukaryotic cells (NIH-3T3). To determine the specific 5-HT_{1A} receptor binding, [³H]8-OH-DPAT was used as radioligand. The selective 5-HT_{1A} receptor agonist bound only a single class of saturable high-affinity binding sites with pharmacological characteristics similar to those of the mammalian 5-HT_{1A} receptor. The effects of 5-HT_{1A} receptor activation on cell growth were also investigated in stably transfected NIH-3T3 cells. The 5-HT_{1A} agonist 8-OH-DPAT was found to increase DNA synthesis and accelerated cell growth.

Cha, J.-H. J., S. L. Kinsman, et al. (1994). "RNA editing of a human glutamate receptor subunit." Molecular Brain Research **22**(1-4): 323.

<http://www.sciencedirect.com/science/article/B6T07-485P8V9-19/2/c0500dcda820d504a2271e0d73453a48>

AMPA receptors are comprised of individual subunits, and the divalent cation permeability of assembled AMPA receptors is determined by a single amino acid residue in the second transmembrane region of the GluR-B subunit. At this site, GluR-B subunits contain an arginine while other AMPA receptor subunits contain glutamine. Interestingly, the murine gene for GluR-B actually specifies a glutamine at the divalent cation permeability site. The appearance of arginine and not glutamine in the mature GluR-B protein is thought to be a result of RNA editing of the GluR-B messenger RNA. In that AMPA receptors are thought to mediate the bulk of fast excitatory signalling within the mammalian central nervous system, this process of RNA editing may play a pivotal role in normal neural function by mediating divalent cation permeability of AMPA receptors. Disruptions of RNA editing could lead to phenotypically altered AMPA receptors, with implications for pathogenic brain processes. We report that the human GluR-B gene sequence is also edited such that there is a difference between the human GluR-B gene and the complementary DNA (cDNA), as demonstrated both with allele-specific polymerase chain reaction (PCR) and restriction enzyme digestion of PCR products. Thus, as in the rodent brain, RNA editing of an AMPA receptor subunit appears to be an important process in the human brain. Disruptions of RNA editing may have neuropathological consequences.

Chan, S. O., W. D. Lyman, et al. (1997). "Temporal and spatial expression of glutamic acid decarboxylases in human fetal brain." Molecular Brain Research **46**(1-2): 318.

<http://www.sciencedirect.com/science/article/B6T07-3R37W4K-19/2/816a9e62d44b56bfc9d7ad63874b4af8>

The expression of two isoforms of glutamic acid decarboxylase, GAD67 and GAD65, was analyzed in central nervous system (CNS) tissues obtained from normal second trimester human fetuses after elective termination of pregnancy. After RT-PCR amplification of sequences contained in total RNA extracts, Southern blotting indicated that GAD67 and GAD65 mRNAs can be detected in frontal pole tissue as early as the 12th week of gestation (12 GW). GAD67 message is strongly expressed during early second trimester and decreases slightly thereafter but remains abundant. In contrast, GAD65 message decreases rapidly and becomes

undetectable by the 19 GW. However, GAD67 and GAD65 are similar in their spatial expression in the CNS at 22 GW. GAD67 and GAD65 messages are highly expressed in the cerebellum but expressed in low levels, if at all, in the spinal cord during this gestational period. These results suggest that GAD67 may have a greater role in neuron differentiation than GAD65 during human brain development.

Chang, A., P. P. Li, et al. (2003). "cAMP-Dependent protein kinase (PKA) subunit mRNA levels in postmortem brain from patients with bipolar affective disorder (BD)." Molecular Brain Research **116**(1-2): 27.

<http://www.sciencedirect.com/science/article/B6T07-493HSMV-1/2/6a6be20939e0fcd0bfb66ce0620b8f5a>

Earlier findings of elevated basal and stimulated PKA activities, and increased immunoreactive levels of PKA regulatory and catalytic subunits in discrete postmortem brain regions from bipolar disorder (BD) patients suggest that disturbances in PKA are involved in the pathophysiology of BD. PKA subunit mRNA levels were measured using SYBR Green real-time RT-PCR to determine if previously observed differences in immunoreactive levels of PKA RII[beta] and C[alpha] subunits were associated with corresponding changes in mRNA levels in temporal and frontal cortices from the same BD patients and matched controls. In distinct contrast to the higher immunolabeling levels of the PKA subunits previously reported in the BD brain, there were no significant differences in RII[beta] and C[alpha] subunit mRNA levels in the temporal and frontal cortices of BD patients compared with controls. These findings infer that the elevated PKA immunolabeling and activity found in the selected cerebral cortical regions of BD postmortem brain were due to a posttranscriptional mechanism, rather than changes in regulation of gene transcription and/or mRNA stability of the PKA subunits.

Chiang, L. W., F. E. Schweizer, et al. (1994). "Nitric oxide synthase expression in single hippocampal neurons." Molecular Brain Research **27**(1): 183.

<http://www.sciencedirect.com/science/article/B6T07-485P5VK-X/2/3f06c0f9a0b2d0a419a36db01df6edc0>

The presence of nitric oxide synthase (NOS) in CA1 pyramidal cells of the rat hippocampus was demonstrated by single-cell PCR. NOS-specific primers were used to amplify mRNA isolated from single hippocampal neurons. The sequence of the major amplification-product obtained was identical to that of the constitutively expressed brain-isoform of NOS. These results confirm immunocytochemical data that NOS is present in CA1, and, therefore, nitric oxide could function as a retrograde messenger in long-term potentiation.

Chinta, S. J., H. V. Pai, et al. (2002). "Constitutive expression and localization of the major drug metabolizing enzyme, cytochrome P4502D in human brain." Molecular Brain Research **103**(1-2): 49.

<http://www.sciencedirect.com/science/article/B6T07-45W39G4-1/2/2a8f796fe179fe2bf855d05b37e4c913>

Cytochrome P4502D6, an important isoform of cytochrome P450, mediates the metabolism of several psychoactive drugs in liver. Quantitatively, liver is the major drug metabolizing organ,

however metabolism of drugs in brain could modulate pharmacological and pharmacodynamic effects of psychoactive drugs at their site of action and explain some of the variation typically seen in patient population. We have measured cytochrome P450 content and examined constitutive expression of CYP2D mRNA and protein in human brain regions by reverse transcription polymerase chain reaction, Northern and immunoblotting and localized it by in situ hybridization and immunohistochemistry. CYP2D mRNA was expressed constitutively in neurons of cerebral cortex, Purkinje and granule cell layers of cerebellum, reticular neurons of midbrain and pyramidal neurons of CA1, CA2 and CA3 subfields of hippocampus. Immunoblot studies demonstrated the presence of cytochrome P4502D protein in cortex, cerebellum, midbrain, striatum and thalamus of human brain. Immunohistochemical localization showed the predominant presence of cytochrome P4502D not only in neuronal soma but also in dendrites of Purkinje and cortical neurons. These studies demonstrate constitutive expression of cytochrome P4502D in neuronal cell population in human brain, indicating its possible role in metabolism of psychoactive drugs directly at or near their site of action, in neurons, in human brain.

Cho, T. T. and A. I. Farbman (1999). "Neurotrophin receptors in the geniculate ganglion." Molecular Brain Research **68**(1-2): 1.

<http://www.sciencedirect.com/science/article/B6T07-3WF80M0-1/2/fa75e295e8ecdcb5918eeee4f9465388>

We examined the distribution of the high affinity neurotrophin receptors (trkA, trkB, and trkC) in the rat geniculate ganglion. Previous work had shown that during early (prenatal) development, trkB and its two ligands, BDNF and NT-4/5, were most important for survival of almost all neurons. Using nested polymerase chain reaction (PCR), we showed that trkA, trkB, and trkC transcripts were expressed, and the mRNAs for trkB and trkC were more abundant than that for trkA. We modified and improved the method for direct reverse transcription in situ PCR and localized trkB mRNA in approximately one third of the neurons in the ganglion. Immunohistochemical data confirmed that approximately the same fraction of neurons was immunoreactive with antibody vs. trkB, and an approximately equal fraction was immunoreactive with trkC antibody. These results are consistent with the notion that both BDNF/trkB and NT-3/trkC play important roles in maintenance of the geniculate ganglion neurons and possibly the peripheral taste system in the young postnatal rat.

Cho, Y., T.-W. L. Gong, et al. (2004). "Noise overstimulation induces immediate early genes in the rat cochlea." Molecular Brain Research **130**(1-2): 134.

<http://www.sciencedirect.com/science/article/B6T07-4D5JY3F-2/2/b456e67680c101b0eeec53b3b1a33764>

In mammals, exposure to intense noise produces a permanent hearing loss called permanent threshold shift (PTS), whereas a moderate noise produces only a temporary threshold shift (TTS). Little is known about the molecular responses to such high intensity noise exposures. In this study we used gene arrays to examine the early response to acoustic overstimulation in the rat cochlea. We compared cochlear RNA from noise-exposed rats with RNA from unexposed controls. The intense PTS noise induced several immediate early genes encoding both transcription factors (c-FOS, EGR1, NUR77/TR3) and cytokines (PC3/BTG2, LIF and IP10). In contrast, the TTS noise down-regulated the gene for growth hormone. The response of these genes to different noise intensities was examined by quantitative RT-PCR 2.5 h after the 90-min noise exposure. For most genes, the extent of induction correlates with the intensity of the noise exposure. Three proteins (EGR1, NUR77/TR3, and IP10) were detected in many regions of the unexposed cochlea. After exposure to 120 dB noise, these proteins were present at higher levels

or showed extended expression in additional regions of the cochlea. LIF was undetectable in the cochlea of unexposed rats, but could be seen in the organ of Corti and spiral ganglion neurons following noise. NUR77/TR3 was a nuclear protein before noise, but following noise translocated to the cytoplasm. These studies provide new insights into the molecular response to noise overstimulation in the mammalian cochlea.

Citron, B. A., J. E. Zoloty, et al. "Tissue transglutaminase during mouse central nervous system development: Lack of alternative RNA processing and implications for its role(s) in murine models of neurotrauma and neurodegeneration." **Molecular Brain Research In Press, Corrected Proof**
<http://www.sciencedirect.com/science/article/B6T07-4FDJ7C8-2/2/5831e75b6eee3a5e4f6b30375e5b4714>

Tissue transglutaminase (tTG) is a member of a multigene family principally involved in catalyzing the formation of protein cross-links. Unlike other members of the transglutaminase family, tTG is multifunctional since it also serves as a guanosine triphosphate (GTP) binding protein (G[alpha]h) and participates in cell adhesion. Different isoforms of tTG can be produced by proteolysis or alternative splicing. We find that tTG mRNA is expressed at low levels in the mouse CNS relative to other tissues, and at lower levels in the CNS of mouse in comparison to that of human or rat. tTG mRNA levels are higher in the heart compared to the CNS, for example, and much higher in the liver. Within the CNS, tTG message is lowest in the adult cerebellum and thalamus and highest in the frontal cortex and striatum. In the hippocampus, tTG expression is highest during embryonic development and falls off dramatically after 1 week of life. We did not find alternative splicing of the mouse tTG. At the protein level, the predominant isoform is [not, vert, similar]62 kDa. In summary, tTG, an important factor in neuronal survival, is expressed at low levels in the mouse CNS and, unlike rat and human tTG, does not appear to be regulated by alternative splicing. These findings have implications for analyses of rodent tTG expression in human neurodegenerative and neurotrauma models where alternative processing may be an attractive pathogenetic mechanism. They further impact on drug discovery paradigms, where modulation of activity may have therapeutic value.

Confaloni, A., A. Crestini, et al. "Rat nicastrin gene: cDNA isolation, mRNA variants and expression pattern analysis." **Molecular Brain Research In Press, Corrected Proof**
<http://www.sciencedirect.com/science/article/B6T07-4FPX2GC-1/2/8deec95a53ff24b033675b5ae2cf212a>

Nicastrin is a type 1 transmembrane glycoprotein that interacts with presenilin, Aph-1, and Pen-2 proteins to form a high molecular complex with gamma secretase activity. Then, nicastrin has a central role in presenilin-mediated processing of beta-amyloid precursor protein and in some aspects of Notch/glp-1 signaling in vivo. Here, we isolated a rat nicastrin cDNA and investigated gene expression in embryonic and adult rat tissues. The predicted amino acid sequence is comprised of 708 residues and showed a high degree of identity with other vertebrate orthologs. Besides full-length nicastrin mRNA, we identified an alternative spliced variant lacking the whole exon 3 and predicted to encode a 62-residue-long truncated protein. Full-length nicastrin mRNA was observed to be ubiquitously expressed, while the spliced variant was preferentially transcribed in the nervous system, whether in embryonic or adult neural tissues. Studies performed on primary cell cultures demonstrated that the short isoform was expressed in neurons, but not in astrocyte and microglial cells. Further experiments performed to verify the presence of the variant in neuroblastoma culture failed to show any truncated protein. Treatments by cyclohexamide showed the involvement of a quality control-based surveillance mechanism, which selectively degrades the exon 3-skipped isoform. In summary, this is the first report describing a novel skipped isoform of nicastrin which may suggest a new possible control mechanism based on the alternative splicing and nonsense-mediated mRNA decay to regulate

brain protein expression and provide newer insights into potential implication in Alzheimer's disease.

Connell, J. W., T. Rodriguez-Martin, et al. "Quantitative analysis of tau isoform transcripts in sporadic tauopathies." Molecular Brain Research **In Press, Corrected Proof**
<http://www.sciencedirect.com/science/article/B6T07-4FTS2RH-1/2/7f309513c5ecec1d7144f877a22cd2ed>

A number of neurodegenerative diseases, including Alzheimer's disease (AD), are characterized by intraneuronal accumulation of the tau protein. Some forms of FTDP-17 are caused by mutations in the tau gene affecting exon 10 splicing. Therefore, dysregulation of tau pre-mRNA splicing may be a contributing factor to sporadic tauopathies. To address this question, we devised a real-time RT-PCR strategy based on the use of a single fluorogenic probe to evaluate the ratio between tau isoforms containing or lacking exon 10 (4R/3R ratio) in post-mortem brain samples. We found a two- to six-fold increase in the 4R/3R ratio in cases of FTDP-17 linked to a splice site mutation, hence confirming the validity of the strategy. The difference in the 4R/3R ratio in the superior temporal and superior frontal gyri between AD and control brains was not statistically significant. Similarly, there was no significant difference in the 4R/3R ratio between Pick's disease cases and controls, indicating that the predominance of tau3R protein in PiD reflects post-translational modifications of specific isoforms. This study indicates that post-translational events are likely to be the main factors controlling tau isoform composition in sporadic tauopathies and highlights the benefit of quantitative RT-PCR in the assessment of splicing abnormalities in tauopathies.

Crispino, M., C. P. Capano, et al. (2001). "Messenger RNAs in synaptosomal fractions from rat brain." Molecular Brain Research **97**(2): 171.

<http://www.sciencedirect.com/science/article/B6T07-44MGNFC-1/2/94cbbb85282bc585a0f5919085e6cc41>

Synaptosomal fractions from rat brain have been analyzed with semi-quantitative RT-PCR methods to determine their content of mRNAs coding for presynaptic, postsynaptic, glial, and neuronal proteins. Each mRNA was determined with reference to the standard HPRT mRNA. In our analyses, mRNAs were considered to be associated with synaptosomes only if their relative amounts were higher than in microsomes prepared in a polysome stabilizing medium, rich in Mg⁺⁺ and K⁺ ions, or in the homogenate. According to this stringent criterion, the following synaptosomal mRNAs could not be attributed to microsomal contamination and were assumed to derive from the subcellular structures known to harbor their translation products, i.e. GAT-1 mRNAs from presynaptic terminals and glial processes, MAP2 mRNA from dendrites, GFAP mRNA from glial processes, and TAU mRNA from neuronal fragments. This interpretation is in agreement with the involvement of extrasomatic mRNAs in local translation processes.

D'Arcangelo, G., G. G. Miao, et al. (1996). "Detection of the reelin breakpoint in reeler mice." Molecular Brain Research **39**(1-2): 234.

<http://www.sciencedirect.com/science/article/B6T07-3W496SN-VI/2/a9ddfebea06ae9cf7529cc41dfa24116>

Disruption of the reelin gene by partial deletion causes the neurological phenotype known as

reeler. Here we report the cloning and sequencing of the reelin breakpoint region from the Jackson reeler strain (rl). Based on this sequence, we developed a polymerase chain reaction screen that allows the identification of mutant mice prior to the appearance of the phenotype. The assay also permits discrimination of heterozygous from wild-type mice. These findings provide a strategy for the characterization of the early anatomical and physiological consequences of the reeler mutation.

Duzhy, D. E., Y. Sakai, et al. (2004). "Cloning and developmental expression of Shaker potassium channels in the cochlea of the chicken." Molecular Brain Research **121**(1-2): 70.

<http://www.sciencedirect.com/science/article/B6T07-4BCXM1S-3/2/c39719b36d4e0fa7f9ba290eafa25ef1>

Signal coding by the receptor and neuronal cells of the auditory system involves various ion channels that modulate a sound stimulus. The genes that encode a number of these ion channels and their accessory subunits are presently unknown for channels found in the sensory epithelium and cochlear nerve. Among these genes are those that encode delayed rectifier and transient type potassium channels found in both the sensory cells and the ganglion. Here, we report the cloning and developmental expression of Shaker family members that include cKv1.2, cKv1.3, cKv1.5, and the Shaker-related cGMP-gated potassium channel cKCNA10. Clones were obtained by screening a chicken embryonic cochlea cDNA library using, as a probe, a mixture of two DNA fragments of cKv1.2 and cKv1.3 obtained by the reverse transcription polymerase chain reaction (RT-PCR). Sequence analysis revealed chicken homologues of Kv1.2, Kv1.3, Kv1.5 and cGMP-gated potassium channels with a deduced amino acid homology of 96-98%, 82-84%, 67-71% and 67-79% to correspondent mammalian homologues. During development of chicken inner ear, RT-PCR studies show expression of cKv1.2, cKv1.3 and cKv1.5 as early as Embryonic Day (ED) 3, while cKCNA10 was detected at low levels beginning on ED6 and was highly expressed by ED9. Additionally, analysis of expression in different parts of the cochlea showed that these genes were co-expressed in different regions of the cochlea, including the cochlear ganglion, sensory epithelium, lagena, and tegmentum. This expression pattern suggests the potential for the formation of heteromeric channels from the corresponding [alpha]-subunits in these various tissues.

Edwards, M. A., R. A. Loxley, et al. (2004). "Unique levels of expression of N-methyl--aspartate receptor subunits and neuronal nitric oxide synthase in the rostral ventrolateral medulla of the spontaneously hypertensive rat." Molecular Brain Research **129**(1-2): 33.

<http://www.sciencedirect.com/science/article/B6T07-4CYWTB0-1/2/05fcbd08b048b0f14502ee991abf8887>

The rostral ventrolateral medulla (RVLM) is the major brainstem region contributing to sympathetic control of blood pressure. We have compared the expression of N-methyl--aspartate (NMDA) receptor subunits (NR1, NR2A-D), NR1 splice variants (NR1-1a/1b, -2a/2b, -3a/3b, -4a/4b), and the neuronal and inducible isoforms of NO synthase (nNOS and iNOS) in the RVLM of Wistar Kyoto (WKY) and spontaneously hypertensive rats (SHR), based on the hypothesis that altered NMDA receptor make-up or altered expression of endogenous NO may be associated with the increase in sympathetic output described from this site in hypertension. Total RNA was extracted and reverse transcribed from the RVLM of mature male WKY and SHR (16-23 weeks). Conventional polymerase chain reaction (PCR) indicated that only the NR1 splice variants NR1-2a, NR1-2b, NR1-4a and NR1-4b were expressed in the RVLM of either species. Quantitative real-time PCR indicated that for both strains of rat, mRNA for the NR1 subunit (all splice variants) was the most abundant (16.5-fold greater, $P \leq 0.05$). This was confirmed

immunohistochemically for nNOS expression. These results demonstrate differential expression levels of NMDA receptor subunits and NOS isoforms in the RVLM region of SHR when compared to WKY rats.

Eva, C., M. Fusco, et al. (1992). "Nerve growth factor modulates the expression of muscarinic cholinergic receptor messenger RNA in telencephalic neuronal cultures from newborn rat brain." Molecular Brain Research **14**(4): 344.

<http://www.sciencedirect.com/science/article/B6T07-484NCGY-8B/2/43984521b2b5503a4195ed91973bdc48>

The effect of nerve growth factor (NGF) on muscarinic receptor subtypes was investigated in a primary culture of telencephalic neurons prepared from neonatal rats. The treatment with 100 ng/ml of NGF significantly enhanced choline acetyltransferase (ChAT) activity and intracellular acetylcholine (ACh) content during cultivation. The same treatment induced an early transient increase of the number of muscarinic cholinergic receptors (mAChR), as measured by [3H]quinuclidinyl benzilate binding to cell homogenate, that was followed by a dramatic decrease of the receptor density from the 9th day of culture. Atropine completely prevented the decrease of the maximal number of muscarinic recognition sites induced by NGF. Prolonged exposure of telencephalic neurons to NGF also induced a significant reduction of the relative content of the messenger RNA (mRNA) encoding m1 and m3 receptors, while the m4 transcript was increased by the treatment. We suggest that the prolonged stimulation of cholinergic neurons by NGF induces a downregulation of m1 and m3 mAChR and their mRNAs on the postsynaptic site, while it increases the synthesis of the functionally distinct m4 receptor subtype, which might be presynaptically localized on cholinergic neurons. The transient increase of the receptor number that occurs at the first days of culture was not paralleled by changes in the relative content of mAChR mRNAs and might be associated with the trophic activity of NGF on cholinergic synapses during early development.

Fathi, Z., P. M. Battaglini, et al. (1998). "Molecular characterization, pharmacological properties and chromosomal localization of the human GALR2 galanin receptor." Molecular Brain Research **58**(1-2): 156.

<http://www.sciencedirect.com/science/article/B6T07-3T8P2J7-J/2/f1a247a9f5c544cf6c313c20f964e2ed>

The neuropeptide galanin mediates a diverse spectrum of biological activities by interacting with specific G protein-coupled receptors. We have used homology genomic library screening and polymerase chain reaction (PCR) techniques to isolate both genomic and cDNA clones encoding the human homolog of the recently cloned rat GALR2 galanin receptor. By fluorescence in situ hybridization, the gene encoding human GALR2 (GALNR2) has been localized to chromosome 17q25.3. The two coding exons of the human GALNR2 gene, interrupted by an intron positioned at the end of transmembrane domain III, encode a 387 amino acid G protein-coupled receptor with 87% overall amino acid identity with rat GALR2. In HEK-293 cells stably expressing human GALR2, binding of porcine galanin is saturable and can be displaced by galanin, amino-terminal galanin fragments and chimeric galanin peptides but not by carboxy-terminal galanin fragments. In HEK-293 cells, human GALR2 couples both to G[alpha]q/11 to stimulate phospholipase C and increase intracellular calcium levels and to G[alpha]i/o to inhibit forskolin-stimulated intracellular cAMP accumulation. A wide tissue distribution is observed by reverse transcriptase (RT)-PCR analysis, with human GALR2 mRNA being detected in many areas of the human central nervous system as well as in peripheral tissues.

Fathi, Z., A. M. Cunningham, et al. (1997). "Cloning, pharmacological characterization and distribution of a novel galanin receptor." Molecular Brain Research **51**(1-2): 49.

<http://www.sciencedirect.com/science/article/B6T07-3S1PFHR-7/2/fbc6dfc28bd830046d2ad2f941cb3d01>

The neuropeptide galanin mediates a diverse spectrum of biological activities by interacting with specific G-protein-coupled receptors. Through expression cloning, human and rat GALR1 receptor cDNA clones have previously been isolated and characterized. In this study, we have used homology screening to isolate a rat brain cDNA clone encoding a second galanin receptor subtype, the GALR2 receptor. The isolated cDNA encodes a 372-amino-acid G-protein-coupled receptor that shares 38% overall amino-acid identity with the rat GALR1 receptor. The pharmacological profile of the rat GALR2 receptor is similar to that of the rat GALR1 receptor. The rat GALR2 receptor binds galanin, N-terminal galanin fragments, and the putative galanin receptor antagonists galantide, C7, M35 and M40 with high affinity but it does not bind C-terminal galanin fragments. Galanin increases intracellular inositol phosphate levels in HEK 293 cells expressing the rat GALR2 receptor via a pertussis toxin-insensitive G-protein. The rat GALR2 receptor mRNA is highly expressed in several brain regions, including hypothalamus and hippocampus as well as the anterior pituitary, with lower levels of expression detected in amygdala, and regions of cortex. It is also highly expressed in the GH3 pituitary cell line and in gut tissues, and to a lower extent in spleen, lung, skeletal muscle, heart, kidney, liver and testis. These results suggest that GALR2 receptor mediates galanin's regulation of pituitary hormone secretion and possibly food intake.

Follesa, P. and M. K. Ticku (1995). "Chronic ethanol treatment differentially regulates NMDA receptor subunit mRNA expression in rat brain." Molecular Brain Research **29**(1): 99.

<http://www.sciencedirect.com/science/article/B6T07-3YGV58W-15/2/fe86e448ee542cd93457126f984ee1db>

Previous studies have implicated the N-methyl--aspartate receptor (NMDAR) complex in the physical dependence and withdrawal effects of chronic ethanol administration. In this study, we examined the effect of chronic ethanol administration and ethanol withdrawal on the NMDAR subunit R1, R2A, R2B, and R2C mRNA levels in rat hippocampus, cerebral cortex, and cerebellum. Using the RNase protection assay, we compared the levels of the NMDAR subunits mRNAs in ethanol-treated and control rats. Our results indicate that chronic ethanol administration and ethanol withdrawal do not change the NMDAR R1 subunit mRNA levels in cerebral cortex, hippocampus, or cerebellum at any time point. In contrast, 9 h after the last ethanol administration the R2A and R2B mRNA subunits were elevated by [ap] 40% in cerebral cortex, and [ap] 30% in hippocampus with respect to the levels in control animals. At 48 h the mRNA levels returned to the control levels. The chronic ethanol treatment did not alter R1, R2A, and R2C subunit mRNA levels in cerebellum. Our results demonstrate that chronic ethanol administration produces a differential regulation of the genes encoding the various subunits of the NMDAR.

Frostholm, A., J. E. Evans, et al. (2000). "Harmaline-induced changes in gamma aminobutyric acidA receptor subunit mRNA expression in murine olivocerebellar nuclei." Molecular Brain Research **85**(1-2): 200.

<http://www.sciencedirect.com/science/article/B6T07-423JKMG-S/2/2bd304c420a855db2090501da7f53522>

Increased CNS activity in the form of electrically or chemically induced seizures is known to alter the properties of GABAA receptors. The tremorgen, harmaline, causes a bursting pattern of activity in inferior olivary neurons, the effects of which are transmitted throughout the olivocerebellar circuit to other regions of the CNS. In situ hybridization was used to determine the effect of this increased activity on gamma aminobutyric acidA (GABAA) receptor subunit gene expression in the cerebellar Purkinje cell layer, deep cerebellar nuclei and inferior olivary complex of adult mice. In Purkinje cells, the expression of [alpha]1, [beta]2, and [gamma]2 mRNAs was increased only slightly (2 transcript levels were initially elevated (26%), but dropped to control levels immediately thereafter. The expression of [alpha]2, [alpha]4, [beta]3 and [gamma]1 mRNAs in olivary neurons was affected differentially by harmaline administration. The [alpha]4 transcript was increased, reaching >60% above control levels at 6 h post-injection. A smaller increase was observed for [alpha]2 mRNA, while [beta]3 and [gamma]1 transcripts dropped below control levels during the same period. The expression of corticotropin-releasing factor mRNA was also elevated in the olivary complex. These data indicate that while Purkinje cells and deep cerebellar neurons are only minimally affected, harmaline induced changes in cellular properties may result in increased numbers of [alpha]4-containing, diazepam-insensitive, GABAA receptors in olivary neurons.

Frostholm, A., D. Zdilar, et al. (1992). "Ontogeny of GABAA/benzodiazepine receptor subunit mRNAs in the murine inferior olive: transient appearance of [beta]3 subunit mRNA and [3H]muscimol binding sites." Molecular Brain Research **16**(3-4): 246.

<http://www.sciencedirect.com/science/article/B6T07-485H1Y9-B/2/47c8f2c54d45c5ac5ceb0f58b1e86541>

The GABAA/benzodiazepine receptor consists of at least four subunits, [alpha], [beta], [gamma] and [delta], each comprised of several variants. The developmental expression of the [alpha]1, [beta]1-3, [gamma]2 and [delta] subunits was studied in the murine inferior olivary nucleus by in situ hybridization with antisense cRNA probes. The postnatal appearance and distribution of [3H]flunitrazepam and [3H]muscimol binding sites, [alpha] and [beta] subunit-specific ligands respectively, were also studied autoradiographically. The [beta]3 subunit was transiently expressed in each of the subnuclei of the inferior olive: The signal was strong at birth, increased throughout postnatal week 1 and rapidly declined thereafter to low adult levels. A similar pattern of labeling was observed with [3H]muscimol. Detectable levels of [alpha]1 subunit mRNA hybridization signal and [3H]flunitrazepam binding sites were also present in the inferior olive at birth, decreasing thereafter. Low to moderate levels of [beta]1, [beta]2, and [gamma]2 subunit mRNAs were present in olivary neurons throughout postnatal development, while [delta] mRNAs were largely absent. It has been reported previously that, during the 2nd postnatal week, the ratio of climbing fiber terminals to Purkinje cells is reduced from 3: 1, as observed in neonates, to the 1: 1 relationship observed in the adult cerebellar cortex. Our results raise the possibility that the subunit composition of the GABAA/benzodiazepine receptor in inferior olivary neurons undergoes changes during development, and that this process may be related to the elimination of multiple climbing fiber innervation of cerebellar Purkinje cells.

Gerhart, D. Z., R. L. Leino, et al. (1994). "GLUT1 and GLUT3 gene expression in gerbil brain following brief ischemia: an in situ hybridization study." Molecular Brain Research **25**(3-4): 313.

<http://www.sciencedirect.com/science/article/B6T07-485H291-5M/2/846ced34a13e585f5e11b131d288d1dd>

GLUT1 and GLUT3 mRNAs in normal and post-ischemic gerbil brains were examined qualitatively and semi-quantitatively using in situ hybridization in conjunction with image analysis. Coronal brain sections at the level of the anterior hippocampus were prepared three hours, one day, and three days after animals were subjected to six min of ischemia. The sections were hybridized with vector- and PCR-generated RNA probes labeled with 35S. Microscopic evaluation of hybridized brain sections coated with autoradiographic emulsion indicated that GLUT1 mRNA was associated with brain microvessels, choroid plexus, and some ependymal cells. GLUT1 mRNA was not observed in neurons, except that one day following ischemia, this mRNA was induced in neurons of the dentate gyrus. GLUT3 mRNA was detected only in neurons. Image analysis of film autoradiograms revealed that both the GLUT1 and GLUT3 messages increased following ischemia but returned nearly to control levels by day three. In the CA1 region of the hippocampus the increase in GLUT3 mRNA was not statistically significant, and by day three the level had fallen significantly below the control, coinciding with the degeneration of the CA1 neurons. Our results suggest that the brain possesses mechanisms for induction and up-regulation of glucose transporter gene expression.

Grafstein-Dunn, E., K. H. Young, et al. (2001). "Regional distribution of regulators of G-protein signaling (RGS) 1, 2, 13, 14, 16, and GAIP messenger ribonucleic acids by in situ hybridization in rat brain." Molecular Brain Research **88**(1-2): 113.

<http://www.sciencedirect.com/science/article/B6T07-42R0S6R-K/2/fa475951770b91b954868b009faea808>

Regulators of G-protein signaling (RGS) proteins are a novel family of GTPase-activating proteins that interact with G[alpha] subunits of the Gi/o, Gz, Gq and G12/13 subfamilies to dampen G-protein-coupled receptor (GPCR)-mediated signaling by accelerating intrinsic G[alpha]-GTPase activity. In the present study, we report on messenger ribonucleic acid (mRNA) localization in rat brain of six RGS genes by in situ hybridization. The distribution patterns of RGS2, RGS13, RGS14 and GAIP (G[alpha] interacting protein) overlapped in most brain regions examined. Highest regional expression was observed for RGS2 in the cerebral cortical layers, striatum, hippocampal formation, several thalamic and hypothalamic nuclei and hindbrain regions such as the pontine, interpeduncular and dorsal raphe nuclei. Levels of RGS14 mRNA closely paralleled those of RGS2 expression levels throughout most brain regions. RGS13 mRNA was enriched in the hippocampal formation, amygdala, mammillary nuclei as well as the pontine and interpeduncular nuclei. GAIP expression levels were highest in the hippocampal formation with moderate to low levels present in all other regions studied. Of the six RGS genes probed, RGS16 mRNA displayed a discrete localization predominantly in the thalamic midline/intralaminar and principal relay nuclei, and the hypothalamic suprachiasmatic nucleus. RGS1 mRNA signal was not detected in brain. In conclusion, the in situ hybridization studies for RGS2, RGS13, RGS14, RGS16 and GAIP mRNAs extend our knowledge of the distribution of RGS genes expressed in the rat central nervous system, and indicate overlapping RGS-enriched regions that may be indicative of functional diversification in GPCR signaling pathway modulation.

Gray, C. W. and A. J. Patel (1993). "Regulation of [beta]-amyloid precursor protein isoform mRNAs by transforming growth factor-[beta]1 and interleukin-1[beta] in astrocytes." Molecular Brain Research **19**(3): 251.

<http://www.sciencedirect.com/science/article/B6T07-4859N5F-7C/2/d7cbd85eea9f1bfff303fb2762fa09bd>

In cultured astrocytes, all three major transcripts of [beta]-amyloid precursor protein (APP) were expressed with the ratio for APP695, APP751 and APP770 isoform mRNAs being 1:4:2. In

comparison with controls, treatment of astrocytes with transforming growth factor-[beta]1 (TGF-[beta]) produced about 6 fold increase in total APP mRNA, while elevation in the interleukin-1[beta] (IL-1[beta]) treated group was small and may relate to the mitogenic effect of IL-1[beta] on astrocytes. Treatment of astrocytes with cytokines also produced marked changes in the upregulation in expression of different APP isoforms. The net increase in mRNAs of KPI-containing isoforms APP751 and APP770 was relatively more than for the APP695 isoform. This phenomenon was mainly related to the differences in the expression of KPI-containing APP isoforms and APP695 isoform in the controls. The present findings provide further evidence for the involvement of astrocytes in a cascade of events leading to the development of senile plaques in Alzheimer's disease and Down's syndrome.

Gubba, E. M., J. W. Fawcett, et al. (2004). "The effects of corticosterone and dehydroepiandrosterone on neurotrophic factor mRNA expression in primary hippocampal and astrocyte cultures." Molecular Brain Research **127**(1-2): 48.

<http://www.sciencedirect.com/science/article/B6T07-4CS4RRD-1/2/2cc31664fb6870b1ec91ec36dd8a773b>

The effects of corticosterone (CORT) and dehydroepiandrosterone (DHEA) on the expression of growth factor mRNA in either primary hippocampal cultures or astrocyte-enriched cultures from E18 CD rats was studied. In mixed primary cultures, 1 [mu]M CORT up-regulated basic fibroblast growth factor (bFGF; FGF2) after 6 h of exposure, but down-regulated nerve growth factor (NGF), brain-derived neurotrophic factor (BDNF) and neurotrophin-3 (NT-3) were unchanged. A 100 [mu]M NMDA alone decreased NT-3, increased BDNF, but had no effect on NGF or FGF2. Concurrently administered CORT had no additional effect on either NGF, BDNF or NT-3, but up-regulated FGF2. In astrocytic cultures, 1 [mu]M CORT increased FGF2 and NT-3, but decreased BDNF and NGF. A dose-response study confirmed these results. DHEA (100 nM) up-regulated NGF after 3 h, but not at other time points (6, 12, 24, 48 h). It had no effect on the other growth factors in mixed primary cultures. In astrocytic cultures, there was no effect of DHEA. Adding DHEA or its sulphate (up to 1 [mu]M) to CORT did not alter the latter's action on growth factor mRNA expression. These results show that CORT has a selective action on growth factor expression, which was greater in astrocytic than in mixed cultures, that CORT amplifies or moderates activity-induced expression following NMDA, but that DHEA does not influence the effects of CORT on growth factor mRNA expression under these conditions.

H. Wheeler-Schilling, T., K. Marquardt, et al. (2000). "Expression of purinergic receptors in bipolar cells of the rat retina." Molecular Brain Research **76**(2): 415.

<http://www.sciencedirect.com/science/article/B6T07-400WXRS-Y/2/5210503c23a7c0e2ea8f2ed6e5337471>

P2X receptors are ligand-gated ion channels which are activated by excitatory neurotransmitter ATP. Despite considerable evidence of signaling by extracellular nucleotides in other sensory systems, P2X receptors in the visual system have only rarely been studied, and almost nothing is known about their functional significance in the retina. To determine whether ATP plays a role in the modulation of vertical retinal signal pathways, we examined the expression of P2X receptor mRNA in freshly isolated bipolar cells of the rat retina (Brown Norway, P25) using the single-cell RT-PCR technique. Positive amplification signals were found in about 33% of the bipolar cells for P2X3, P2X4 and P2X5 but not for P2X7 mRNA. We conclude that at least a subpopulation of bipolar cells in the rat retina expresses ionotropic P2 receptors of the P2X type and that these possibly exert a neuromodulatory influence on information processing in the retina.

Han, S.-H., D. Murchison, et al. "Low voltage-activated calcium and fast tetrodotoxin-resistant sodium currents define subtypes of cholinergic and noncholinergic neurons in rat basal forebrain."

Molecular Brain Research In Press, Corrected Proof

<http://www.sciencedirect.com/science/article/B6T07-4F9F8GX-1/2/725ce0716e4627dbc0b0745f3ca77980>

Neurons of the basal forebrain (BF) possess unique combinations of voltage-gated membrane currents. Here, we describe subtypes of rat basal forebrain neurons based on patch-clamp analysis of low-voltage activated (LVA) calcium and tetrodotoxin-resistant (TTX-R) sodium currents combined with single-cell RT-PCR analysis. Neurons were identified by mRNA expression of choline acetyltransferase (ChAT+, cholinergic) and glutamate decarboxylase (GAD67, GABAergic). Four cell types were encountered: ChAT+, GAD+, ChAT+/GAD+ and ChAT-/GAD- cells. Both ChAT+ and ChAT+/GAD+ cells (71/75) displayed LVA currents and most (34/39) expressed mRNA for LVA Ca²⁺ channel subunits. Cav3.2 was detected in 31/34 cholinergic neurons and Cav3.1 was expressed in 6/34 cells. Three cells expressed both subunits. No single neurons showed Cav3.3 mRNA expression, although BF tissue expression was observed. In young rats (2-4 mo), ChAT+/GAD+ cells displayed larger LVA current densities compared to ChAT+ neurons, while these latter neurons displayed an age-related increase in current densities. Most (29/38) noncholinergic neurons (GAD+ and ChAT-/GAD-) possessed fast TTX-R sodium currents resembling those mediated by Na⁺ channel subunit Nav1.5. This subunit was expressed predominately in noncholinergic neurons. No cholinergic cells (0/75) displayed fast TTX-R currents. The TTX-R currents were faster and larger in GAD+ neurons compared to ChAT-/GAD- neurons. The properties of ChAT+/GAD+ neurons resemble those of ChAT+ neurons, rather than of GAD+ neurons. These results suggest novel features of subtypes of cholinergic and noncholinergic neurons within the BF that may provide new insights for understanding normal BF function.

Harada, N., K. Yamada, et al. (1992). "Regulation of aromatase cytochrome P-450 (estrogen synthetase) transcripts in the quail brain by testosterone." Molecular Brain Research **15**(1-2): 19.

<http://www.sciencedirect.com/science/article/B6T07-4859NCP-9Y/2/65b60ddedd7c10783274c0652e6526da>

The aromatase cytochrome P-450 (P-450AROM) cDNA, which was identified by homologies in the DNA and in the deduced amino acid sequences with human P-450AROM cDNA, was isolated from a brain cDNA library of Japanese quail, demonstrating the presence of RNA transcripts of P-450AROM in the quail brain. To determine trace amounts of P-450AROM mRNA in the brain and to examine the effects of testosterone on its expression, a quantitative PCR method of RNA transcripts was developed. Brain total RNA was subjected to reverse transcription reaction and then quantitated by PCR from cDNA with a fluorescent dye-labeled primer. The quantity of P-450AROM mRNA was calculated by using an internal standard of modified P-450AROM (m-P-450AROM) RNA. The brain P-450AROM was primarily transcribed in the hypothalamus area (1.15±0.14 amol/[μg of RNA) and traces of transcripts only were detected in the cerebellum (0.038±0.005 amol/[μg of RNA). The P-450AROM mRNA in the hypothalamus of castrated quail was low (0.270±0.078 amol/[μg of RNA) and increased 4- to 5-fold following treatment with testosterone. These results demonstrate, for the first time, that the increase in P-450AROM activity that is observed in the brain following treatment with testosterone results from a pretranslational regulation of the P-450AROM by androgens.

Hardin-Pouzet, H., P. Giraudon, et al. (1996). "Glucocorticoid upregulation of glutamate dehydrogenase

gene expression in vitro in astrocytes." Molecular Brain Research **37**(1-2): 324.

<http://www.sciencedirect.com/science/article/B6T07-3WXX2SG-1C/2/7063cc863f74b415313c635944b66a16>

Glutamate, the major excitatory neurotransmitter, is preferentially catabolized in astrocytes by glutamate dehydrogenase (GDH). Treatment of an astrocytic cell line with hydrocortisone (10⁻⁵ M) resulted in increased expression of GDH mRNA. Transfection of the cells with truncated parts of the GDH promoter showed that genomic responsive elements activated by hydrocortisone are localized in the -557/+1 region of the promoter. This control of GDH expression by glucocorticoids may be involved in their protective effect against glutamate excitotoxicity.

Harrison, D. C., R. P. Davis, et al. (2001). "Caspase mRNA expression in a rat model of focal cerebral ischemia." Molecular Brain Research **89**(1-2): 133.

<http://www.sciencedirect.com/science/article/B6T07-42T4FSW-N/2/f9b07d41be65769de0b4f7f2940f8ff3>

Proteins of the caspase family are involved in the signalling pathway that ultimately leads to programmed cell death (apoptosis), which has been reported to occur in some experimental models of stroke. In a previous paper we used quantitative reverse transcription and polymerase chain reaction (RT-PCR) to characterise changes in the mRNA expression of one member of this family, caspase-3, in a rat model of permanent focal ischemia. Here we have used this technique to study the expression of a further three caspases which are involved in different aspects of caspase signalling. Caspase-8, involved in Fas-mediated apoptosis, was upregulated in the cortex of ischemic rats. Caspase-11, which leads to the synthesis of the functional form of the cytokine interleukin-1[beta], also showed increased expression, but with a different temporal profile from caspase-8. In contrast, caspase-9, which forms part of the pathway signalling through the mitochondria, showed a decrease in expression. The expression of a further four caspases (1, 2, 6 and 7) has also been characterised in a simpler experiment. These caspases all showed distinctive patterns of expression following the induction of ischemia. These data lead us to conclude that caspase expression as a whole is under very strict transcriptional control in this model. Certain elements of caspase signalling, such as the Fas-induced pathway and the events upstream of IL-1[beta] processing, are upregulated, while others are not. This may be due to some form of genetic program activated in response to ischemia in the brain and may highlight which biological pathways are modulated.

Harrison, D. C., A. D. Medhurst, et al. (2000). "The use of quantitative RT-PCR to measure mRNA expression in a rat model of focal ischemia -- caspase-3 as a case study." Molecular Brain Research **75**(1): 143.

<http://www.sciencedirect.com/science/article/B6T07-3YDG207-K/2/0a52cbf3332d36fc9d1f0df70e1be77b>

Quantitative reverse transcription and polymerisation chain reaction (RT-PCR) using Taqman(TM) fluorogenic probes has been used to measure changes in gene expression in the cerebral cortex of rats in the permanent middle cerebral artery occlusion (pMCAO) model of focal ischemia. The mRNA levels of three housekeeping genes have been analysed in this model to determine which gene showed least change following experimental insult. In the lesioned cortex, [beta]-actin mRNA increased at 24 h, while the levels of cyclophilin and glyceraldehyde-3-phosphate dehydrogenase (GAPDH) did not change. We have also used this methodology to

examine modulations in the level of caspase-3 mRNA during focal ischemia in the rat. Caspase-3 mRNA showed a 41% increase at 6 h post-MCAO, which was specific to the lesioned cortex. This change became more pronounced with time, showing an increase of 220% at 24 h. This methodology enables changes in mRNA expression to be analysed more sensitively and quantitatively than other available techniques and highlights the need for careful choice of control or housekeeping genes used for RNA comparisons.

Hashimoto, N., H. Yamanaka, et al. (2001). "Expression of hepatocyte growth factor in primary sensory neurons of adult rats." Molecular Brain Research **97**(1): 83.

<http://www.sciencedirect.com/science/article/B6T07-44CNR5J-3/2/622c0f6b0b367e3054eae46cc283f07>

We examined the expression of hepatocyte growth factor (HGF) mRNA and its receptor, c-met mRNA, in the dorsal root ganglia (DRG) and spinal cord of naive adult rats using in situ hybridization histochemistry (ISHH) and the reverse transcription-polymerase chain reaction (RT-PCR) technique. HGF mRNA was expressed in 25.0% of DRG neurons and 80.5% of HGF mRNA-positive neurons expressed trkA mRNA. In the lumbar spinal cord, c-met mRNA signals were observed in the superficial layer of dorsal horn. These results suggest that the HGF/cMet system may be involved in sensory transmission.

Herrington, R. J., S. A. Nanda, et al. (2004). "The effects of acute stress on the regulation of central and basolateral amygdala CRF-binding protein gene expression." Molecular Brain Research **131**(1-2): 17.

<http://www.sciencedirect.com/science/article/B6T07-4DBX7P9-1/2/5d068ef9d8df23989286a2d60d03874a>

Corticotropin-releasing factor (CRF) is a key mediator of the behavioral, autonomic, and endocrine responses to stress. CRF binds two receptors and a CRF-binding protein (CRF-BP), which may inactivate or modulate the actions of CRF at its receptors. The amygdala is an important anatomical substrate for CRF and contains CRF, its receptors, and CRF-BP. Few studies have examined the effects of acute stress on the regulation of amygdala CRF-BP with other CRF system genes. Therefore, we examined the time course of the effects of acute restraint stress on central (CeA) and basolateral (BLA) amygdala CRF system genes. Consistent with our previous study, acute stress increased BLA CRF-BP mRNA shortly after stress offset. Surprisingly, BLA CRF-BP mRNA remained elevated up to 21 h after the stressor. This effect was selective in the BLA as stress did not alter CeA CRF-BP mRNA, and there were no changes in CRF or CRF receptor mRNAs in either amygdala nucleus. These results suggest that alterations in BLA CRF-BP gene expression are a primary response of the BLA/CeA CRF system to acute stress. Because CRF-BP can modulate CRF action, changes in amygdala CRF-BP levels after stress exposure may affect the ability of an organism to adapt to future stressors.

Hirst, W. D., N. Y. Cheung, et al. (1998). "Cultured astrocytes express messenger RNA for multiple serotonin receptor subtypes, without functional coupling of 5-HT₁ receptor subtypes to adenylyl cyclase." Molecular Brain Research **61**(1-2): 90.

<http://www.sciencedirect.com/science/article/B6T07-3TYNN0P-9/2/1085298406828f13fed212546d126127>

The literature describing the expression of 5-HT receptor subtypes by astrocytes is controversial and incomplete. It is clear that primary cultures of astrocytes express receptors of the 5-HT₂ family coupled to phospholipase C and of the 5-HT₇ receptor family positively coupled to adenylyl cyclase. Cultured astrocytes have also been reported to express receptors of the 5-HT₁ family, although the exact subtypes present are unknown. In the present study we have investigated which of the known rat G-protein coupled 5-HT receptor mRNAs are expressed by cultured astrocytes. Reverse transcriptase-polymerase chain reaction (RT-PCR) revealed expression of 5-HT_{1A}, 5-HT_{1B}, 5-HT_{1D}, 5-HT_{1F}, 5-HT_{2A}, 5-HT_{2B}, 5-HT_{2C}, 5-HT_{5B}, 5-HT₆ and 5-HT₇ receptor mRNAs in astrocytes derived from 2-day old rats and cultured for 10-12 days. Messenger RNAs for 5-HT₄ and 5-HT_{5A} receptors were not detected. The functional expression of 5-HT₁ receptor subtypes was investigated by measuring the ability of 5-HT₁ receptor agonists: 8-OH-DPAT (5-HT_{1A} receptors), RU24969 (5-HT_{1A}, 5-HT_{1B}, 5-HT_{1D}, and 5-HT_{1F} receptors) or sumatriptan (5-HT_{1B}, 5-HT_{1D}, and 5-HT_{1F} receptors) to modulate forskolin or isoproterenol stimulated cAMP production. These compounds, at concentrations up to 10 [μ]M, did not significantly attenuate cAMP production. These results indicate that although astrocytes express mRNA for each of the five 5-HT₁ receptor subtypes which have been isolated from the rat, these receptors are not coupled to the inhibition of adenylyl cyclase.

Honkaniemi, J., S. M. Massa, et al. (1996). "Global ischemia induces apoptosis-associated genes in hippocampus." Molecular Brain Research **42**(1): 79.

<http://www.sciencedirect.com/science/article/B6T07-3P8WWD9-B/2/d7a5e5c31045b97fe4222464bb9c4d80>

Using in situ hybridization, Northern blotting and RT-PCR we studied the post-ischemic expression of bcl-2, bcl-x, bax and ICE. One day following 5 min or 10 min of global ischemia bcl-2 and bcl-x mRNAs were induced in CA1 hippocampal pyramidal neurons while bax was unchanged. By 72 h after ischemia the expression of bcl-2, and bcl-x and bax mRNAs decreased in CA1. The large isoform of bcl-x (bcl-xL), detected using RT-PCR, decreased in whole hippocampus by 24-72 h after ischemia relative to the putative short (bcl-xS) and transmembrane deleted (bcl-x[Delta]TM) forms. Oligonucleotides to interleukin-1[beta] convertase (ICE), which detected the expected 2-kb transcript and two lesser 1.5- and 3-kb hybridizing species, demonstrated slight mRNA induction in the CA1 at 72 h following ischemia. DNA nick end-labeling at 3 days following ischemia showed DNA fragmentation in neurons limited to the CA1 region of hippocampus following 5 min ischemia, while DNA fragmentation was detected in CA1, CA3, dentate gyrus and cortical neurons following 10 min ischemia. The data support the view that hippocampal neurons might undergo an apoptosis-like death after global ischemia. Since global ischemia decreases total protein synthesis especially in the CA1 region, the increases in bcl-2 mRNA levels may not necessarily lead to increased Bcl-2 protein levels. This may explain why the CA1 neurons die despite the prominent induction of the protective bcl-2 gene. The observed decrease by 24 h in the bcl-xL/bcl-xS ratio which preceded DNA fragmentation may participate in the cell death produced by ischemia. However, because of the ischemia-induced decrease in total protein synthesis, the decreased bcl-xL/bcl-xS ratio does not necessarily lead to a changed ratio in the amount of the appropriate proteins. Since ICE like mRNA was induced at 72 h when the CA1 neurons were dead, the significance of this ICE-like mRNA induction remains unclear.

Huang, X. C., U. V. Shenoy, et al. (1997). "Modulation of angiotensin II type 2 receptor mRNA in rat hypothalamus and brainstem neuronal cultures by growth factors." Molecular Brain Research **47**(1-2): 229.

<http://www.sciencedirect.com/science/article/B6T07-3S0MHR6->

X/2/ff184324f0223fd780b477872e2bac60

This study investigates the regulatory effects of growth factors upon angiotensin II type 2 (AT2) mRNA levels in neurons co-cultured from newborn rat hypothalamus and brainstem. Incubation of cultured neurons with nerve growth factor (NGF; 5-50 ng/ml) caused time-dependent changes in the steady-state levels of AT2 receptor mRNA. Short-term (0.5-1.0 h) incubations with NGF resulted in significant increases in AT2 receptor mRNA, whereas longer-term incubations (4-24 h) caused significant decreases. Activation of NGF receptors is known to stimulate phospholipase C-[gamma] and subsequently activate protein kinase C (PKC). Incubation of cultures with the PKC activator, phorbol-12-myristate-13-acetate (PMA; 100 nM), caused temporal changes in AT2 receptor mRNA levels similar to those observed with NGF. By contrast, insulin (0.1-10 [mu]g/ml) elicited only significant decreases in AT2 receptor mRNA levels. The observed abilities of NGF and insulin to regulate the expression of AT2 receptor mRNA are consistent with the fact that the AT2 receptor gene promoter region contains several cis DNA regulatory elements that respond to growth factor-stimulated transcription factors. These novel observations which show that NGF and insulin can regulate AT2 receptor mRNA in neurons derived from neonatal rat CNS lend support to the idea that AT2 receptors have a role in development and differentiation.

Ikeda, T., S. Kitayama, et al. (2001). "Nerve growth factor down-regulates the expression of norepinephrine transporter in rat pheochromocytoma (PC12) cells." Molecular Brain Research **86**(1-2): 90.

<http://www.sciencedirect.com/science/article/B6T07-4299Y92-K/2/87062a8394c416703691fbc6736c8823>

Functional expression of norepinephrine transporter (NET) and its regulation were examined in rat pheochromocytoma cell line, PC12. Nerve growth factor (NGF) decreased [3H]-norepinephrine (NE) uptake in association with a decrease in NET mRNA levels. On the other hand, levels of tyrosine hydroxylase mRNA increased in PC12 cells treated with NGF for 4-24 h, while Oct-2 mRNA levels decreased at 4 h with NGF then recovered for 8-24 h in the presence of NGF. Both bFGF and EGF reduced [3H]NE uptake, although they failed to affect NET mRNA levels. To examine the NET transcriptional regulation, we identified the 5'-noncoding region of rat NET mRNA by the rapid amplification of cDNA end (RACE) method and cloned the 5'-flanking region of NET gene. The newly identified exon encodes the untranslated region of rat NET mRNA upstream of the known 5'-region including ATG start codon. Constructs having green fluorescent protein (GFP) as reporter were made with the cloned NET gene, and promoter activity was examined in CHO and SK-N-SH cells transiently transfected and in PC12 cells stably transfected with NET-GFP constructs. The results indicate that the 2.1 kb NET flanking region displays promoter activity and is responsible for the NGF-induced down-regulation of NET expression.

Imaizumi, K., M. Tsuda, et al. (1994). "Differential expression of sgk mRNA, a member of the Ser/Thr protein kinase gene family, in rat brain after CNS injury." Molecular Brain Research **26**(1-2): 189.

<http://www.sciencedirect.com/science/article/B6T07-485RK1F-W/2/4bff8057c15e112190bbf4e74be51300>

We cloned genes the expression of which were induced 3 days after cortical injury of rat brain by a differential display technique, and four novel and known sequences were isolated. Among these sequences, the sgk gene which was recently identified as a novel member of the serine/threonine protein kinase gene family, was selected for analysis of its expression patterns in rat brain by northern blotting and in situ hybridization, because hybridization signals were strong at the lesion

sites. Expression of *sgk* mRNA was induced within 3 days after injury, and was maintained at a high level for at least 14 days. The cells which strongly expressed the *sgk* gene were in the deep layers of the cortex and in the corpus callosum. In situ hybridization analysis for *sgk* and myelin proteolipid protein mRNA using serial sections showed that the distribution of both signals was very similar at the damaged regions. Therefore, it is likely that the *sgk* transcript is expressed by oligodendrocytes after brain injury. Investigation of the developmental expression of the *sgk* gene showed that neurons in layers I and II of the cortex, lateroposterior and laterodorsal thalamic nucleus, and ventral posterolateral and posteromedial thalamic nucleus strongly expressed *sgk* mRNA at postnatal day 1 and day 7, but these neurons showed no expression in fetal or adult brain. These results suggest that the induction of *sgk* gene may be associated with a series of axonal regenerations after brain injury, and in addition, the *sgk* gene may also play important roles in the development of particular groups of neurons in the postnatal brain.

Inoue, K., M. Sakaitani, et al. (1995). "Cloning and expression of a bovine glutamate transporter." Molecular Brain Research **28**(2): 343.

<http://www.sciencedirect.com/science/article/B6T07-3YGV2GR-K/2/b9cbe584de1534d591cb6bd1231207b3>

We have isolated a 3845 base-pair cDNA (BNGLUAS) encoding a bovine glutamate transporter (bovine GLAST) by screening a bovine retina cDNA library with an oligonucleotide probe corresponding to conserved regions of known glutamate transporters. The cDNA sequence predicted a protein of 542 amino acids and displayed 96% and 97% amino acid identity with the rat GLAST/GluT-1 and human GLAST, respectively. Expression of the bovine GLAST in *Xenopus* oocytes revealed Na⁺-dependent [¹⁴C]-glutamate uptake and electrogenic glutamate uptake.

Iwata, N., M. Virkkunen, et al. (1998). "Identification of a naturally occurring Pro15-Ser15 substitution in the serotonin5A receptor gene in alcoholics and healthy volunteers." Molecular Brain Research **58**(1-2): 217.

<http://www.sciencedirect.com/science/article/B6T07-3T8P2J7-S/2/eef45acc7f9019eac16d780ad514343>

We screened the serotonin5A receptor gene coding region in 186 unrelated alcoholic patients and 187 controls. A relatively abundant amino acid substitution and two synonymous DNA substitutions were detected. Two synonymous variants, A12T and C789T, had rarer-allele frequencies of 23% and 1%, respectively. The Pro15Ser substitution is located in the amino terminal, extracellular domain of the receptor adjacent to a putative phosphorylation site. Pro15Ser had rarer-allele frequencies of 8.1% and 5.9% in Finnish alcoholic patients and controls, respectively (p=n.s.).

Jabs, R., E. Guenther, et al. (2000). "Evidence for P2X3, P2X4, P2X5 but not for P2X7 containing purinergic receptors in Muller cells of the rat retina." Molecular Brain Research **76**(2): 205.

<http://www.sciencedirect.com/science/article/B6T07-400WXRS-2/2/64f680b029c163f72e6904434ba3ab0f>

P2X receptors are ligand-gated ion channels activated by ATP. They are expressed in a broad variety of tissues. To date, eight P2X receptor subunits (P2X1-P2X7, P2XM) have been cloned.

In spite of the considerable evidence of signaling by extracellular nucleotides in other sensory systems, only few studies have been undertaken in the retina. In earlier studies, we have demonstrated that there is mRNA expression of the P2X2-5 and P2X7 subunits in the rat retina. In the present study, molecular biological methods were used to investigate expression of P2X receptor mRNA in freshly isolated Muller cells (MCs) of the adult rat retina (Brown Norway). A total of 36 MCs was analyzed, employing the single-cell RT-PCR. A positive amplification signal of 11/14 for P2X3-mRNA, 5/10 for P2X4-mRNA, 3/10 for P2X5-mRNA and 0/8 for P2X7-mRNA was revealed. Additionally, the astroglial identity of the cells under studied was confirmed in 10 cases by simultaneous amplification of RT-PCR products of glutamine synthetase (GS)- and P2X-mRNA. We conclude that MCs of rat retina express ionotropic P2 receptors, which, in addition to other functions, may play a key role within the recently described long range calcium signaling and the fast direct glia-neuron interactions in the rat retina.

Jeohn, G. H., R. C. C. Chang, et al. (2000). "Post-transcriptional inhibition of lipopolysaccharide-induced expression of inducible nitric oxide synthase by Go6976 in murine microglia." Molecular Brain Research **79**(1-2): 18.

<http://www.sciencedirect.com/science/article/B6T07-40VT3B1-2/2/7f2c5e432fcb2f540b47e674192abf78>

Glia in the brain respond to various toxins with an increased expression of inducible nitric oxide synthase (iNOS) and an increased production of nitric oxide (NO). Here, we report that lipopolysaccharide (LPS)-induced expression of iNOS was down-regulated post-transcriptionally through the destabilization of iNOS mRNA by the indolocarbazole compound, Go6976, in murine microglia. This Go6976 effect is specific for iNOS since tumor necrosis factor [alpha] was unaffected by the compound. Interestingly, the post-transcriptional effects ascribed to Go6976 were not observed with other inhibitors of protein kinase A, C (PKC), G, or protein tyrosine kinases. Instead, these kinases appear to affect the iNOS/NO system at the transcriptional level. In the past, Go6976 has been reported to be a rather specific inhibitor of PKC in vitro. Results from our experiments, through prolonged treatment with phorbol esters and with the various PKC inhibitors including phorbol ester-insensitive PKC isotype inhibitor, suggest that the Go6976-mediated post-transcriptional regulation of iNOS gene expression and NO production in microglia is not mediated through its reputed effects on PKC activity. Since the effects of various neurotoxins and certain neurodegenerative diseases may be manifested through alterations in the iNOS/NO system, post-transcriptional control of this system may represent a novel strategy for therapeutic intervention.

Jeohn, G. H., B. Wilson, et al. (2000). "The indolocarbazole Go6976 protects neurons from lipopolysaccharide/interferon-[gamma]-induced cytotoxicity in murine neuron/glia co-cultures." Molecular Brain Research **79**(1-2): 32.

<http://www.sciencedirect.com/science/article/B6T07-40VT3B1-3/2/e625bfacacf792061a8483aa5ec556f9>

The expression of inducible nitric oxide synthase (iNOS) and the production of nitric oxide (NO) after exposure to endotoxins has been implicated in immune-mediated neurotoxicity. The indolocarbazole compound Go6976, which has been described as a selective protein kinase C (PKC) inhibitor in vitro, rescued neurons from lipopolysaccharide/interferon-[gamma] (LPS/IFN[gamma])- or interleukin-1[alpha]/tumor necrosis [alpha]/IFN[gamma] (IL-1[alpha]/TNF[alpha]/IFN[gamma])-induced cytotoxicity in murine primary neuron-glia co-cultures. Other compounds known to inhibit PKC, Ro31-8220, GF109203X, Go7874, H7, staurosporine and H89, failed to rescue neurons from the LPS/IFN[gamma]-induced cytotoxicity. These results

suggest that the neuroprotection by Go6976 from the LPS/IFN[gamma]-induced neuronal cell death is not mediated through its reputed effects on PKC activity. The neuroprotection paralleled the inhibition of iNOS gene expression and NO production. However, further analyses correlating NO production with the extent of neurotoxicity suggested that additional mechanism(s) besides the inhibition of the iNOS/NO system may be responsible for the neuroprotective effects of Go6976. An understanding of the mechanism underlying the neuroprotective effect of Go6976 may provide key insights into potential interventions for immune-mediated neurodegenerative diseases.

Kasai, K., T. Yamashita, et al. (2003). "Induction of mRNAs and proteins for Na/K ATPase [alpha]1 and [beta]1 subunits following hypoxia/reoxygenation in astrocytes." Molecular Brain Research **110**(1): 38.

<http://www.sciencedirect.com/science/article/B6T07-47FDMXT-1/2/e48bcce151c0a68c6073ad1a19a87883>

Characteristics of the cellular response to oxygen deprivation and subsequent reoxygenation (hypoxia/reoxygenation) include redirection of energy metabolism, increased glucose utilization and expression of oxygen-regulated proteins. Inhibition of protein synthesis during early reoxygenation period prevented effective astrocyte adaptation to hypoxia/reoxygenation, resulting in eventual cell death. To elucidate the role of astrocytes in the central nervous system in response to hypoxia/reoxygenation, we analyzed the cDNA library derived from the cultured rat astrocytes subjected to 24 h of hypoxia followed by reoxygenation by differential display, and isolated a cDNA corresponding to Na/K ATPase [alpha]1 subunit. The expression of Na/K ATPase [alpha]1 subunit mRNA as well as [beta]1 subunit mRNA was transiently increased after reoxygenation, whereas hypoxia itself did not induce any gene expression change. Na/K ATPase [alpha]1 subunit protein was transiently increased, whereas the protein expression for Na/K ATPase [beta]1 subunit showed sustained induction after reoxygenation. Overexpression of [beta]1 subunit in HEK 293 cells subjected to hypoxia/reoxygenation promoted survival of the cells. These findings suggest that Na/K ATPases may contribute to maintain the cellular environment of astrocytes subjected to hypoxia/reoxygenation.

Kashiwagi, K., Y. Iizuka, et al. (2003). "Differences in nitric oxide production: a comparison of retinal ganglion cells and retinal glial cells cultured under hypoxic conditions." Molecular Brain Research **112**(1-2): 126.

<http://www.sciencedirect.com/science/article/B6T07-4841424-5/2/395d975b6fa25ad56807fb7265183fe7>

The aim of this study was to compare the effects of hypoxia on nitric oxide synthase (NOS) expression and the production of NO between isolated retinal ganglion cells (RGCs) and retinal glial cells. Reverse transcription-polymerase chain reaction (RT-PCR) was employed to examine the presence of neuronal NOS mRNA, inducible NOS mRNA, and endothelial NOS mRNAs in the two cell types. RGCs and retinal glial cells were separately cultured under hypoxic (10% O₂) or control (20% O₂) conditions. Changes in NOS-mRNA expression were quantified by real-time PCR, and nitrite in the medium was measured up to 96 h of culture. The effects of non-NOS- and iNOS-selective inhibitors on hypoxia-induced release of nitrite in the culture medium were evaluated. RT-PCR revealed the presence of three types of NOSs in the two types of cultured cells. Hypoxic culture conditions significantly changed the expression of all NOS mRNAs in retinal glial cells but not in RGCs. NO production showed significant changes corresponding to those of NOS mRNAs in retinal glial cells but not in RGCs, and both NOS inhibitors significantly reduced hypoxia-induced nitrite release in retinal glial cells. Retinal glial cells but not RGCs may be the

major source of NO under hypoxic conditions.

Kawano, H., T. Nakatani, et al. (2004). "Identification and characterization of novel developmentally regulated neural-specific proteins, BRINP family." Molecular Brain Research **125**(1-2): 60.

<http://www.sciencedirect.com/science/article/B6T07-4CC80CC-2/2/0e37a8b0314f7eb84b0437b1596c0c07>
